REASSEMBLY: When installing switch plunger make certain that lip on inner end of plunger is down toward manifold (lip will prevent ball engaging on flat of shaft if installed incorrectly). See that adjusting shims are in place under contact spring, and spring seat washer seated on middle leg of contact spring. Coat contact surfaces of terminal cap lightly with Beacon M-285 lubricant or Rocker Arm Grease No. 1 (petroleum jelly can be used if other lubricants not available). *CAUTION*—Do not use other lubricants and do not lubricate switch ball or plunger. Make certain that return spring enters socket in switch cap and that cap is properly seated in counterbore in casting.

STROMBERG STARTER SWITCH

Car Model & Carb.	Stromberg Switch No.
Buick 40, 50, 70 (1948-52)	See Changes (below)
Buick 40 (1952-53) Code 7-90B	386030

Buick 70 (1953) Code 7-94, A, B, C	386030

▷CHANGES, CAUTIONS, CORRECTIONS

▷*STARTER SWITCH CHANGES FOR IMPROVED PERFORMANCE:* Manufacturer recommends that whenever switch being serviced, new parts included in Change-over Kit No. 386260 or new type individual parts as listed below should be used. When these changes made or Replacement Switch installed, *CODE NUMBER should be changed as follows:*

Starter Switch Change

Buick Series	Carb. Code No. Orig.	Change To:	Starter Switch Orig.	Change To:
40, 50 ('48-49)	7-69,A	7-69B	385000	386032
70 ('48-49)	7-70,A	7-70B	385000	386032

70 (Late '51)	7-91	7-91A	385611	386030

▷*STARTER SWITCH PRODUCTION CHANGES:* Several switch types have been used on production carburetors (see Starter Switch listing above). These switches have following features:

Switch Assy. No. 386032—Has light weight contact piston spring for use with carburetors WITHOUT Pump Lever Torsion Spring (Carb. Code 7-88 & 7-89) or WITH LIGHT WEIGHT Torsion Spring (Carb. Code 7-88A & 7-89A). *Switch identified by letter "B" stamped on switch housing.*

Switch Assy. No. 386030—Has heavy contact piston spring for use with carburetors having HEAVY Pump Lever Torsion Spring (Code 7-90 & 7-91). *Switch identified by "C" stamped on switch housing.*

▷*SWITCH PARTS CHANGES & SERVICE CAUTIONS:* New parts (furnished in Change-over Kit 386260 or separately) used for each switch as follows:

Starter Switch Parts Change

New Parts	Starter Switch No. 385000	385611
Assy. Housing & Seal	386033④	⑤386031
Vacuum Piston Seal	386025	386025

①—Orig. Part. Used on Code 7-69, 7-69A, 7-70, 7-70A, 7-88, 7-88A, 7-88B, 7-89, 7-89A, 7-89B, 7-90, 7-90A, 7-91 carburetors.

②—New Felt Filter. Used only on 7-69B, 7-70B, 7-88C, 7-89C, 7-90B, 7-91A carburetors.

③—Used only on Code 7-69B, 7-70B, 7-88C, 7-89C, 7-90B, 7-91A carburetors.

④—Identified by letter "B" stamped on housing. Used also in Switch Assy. No. 386032.

⑤—Identified by letter "C" stamped on housing. Used also in Switch Assy. No. 386030.

DESCRIPTION & OPERATION: Switch is mounted on carburetor and is controlled by an operating lever on the throttle valve shaft (for accelerator pedal starting). The switch contact and slide assembly is spring-loaded and is held up in the "off" position by by the operating lever when the throttle valve is closed. A spring-loaded vacuum piston or slide "latch" is provided to hold the slide in this off position when the engine is running and to prevent the starter operating during closed throttle idling.

▷*NOTE—Switch must be "timed" to insure correct throttle opening when starter operates. See Adjustment data.*

ADJUSTMENT: *CAUTION—Switch timing must be checked and adjusted with carburetor on engine (switch can be timed approximately with carburetor off engine, but setting should be checked AFTER CARBURETOR INSTALLED ON ENGINE.*

Switch Timing (with carburetor on engine): Place transmission in neutral and apply parking brake firmly (to prevent car moving during tests). Set engine hot or slow idle speed at exactly 8 MPH. or 450 RPM. With engine not running, insert #65 drill or wire (such as small paper clip through vacuum piston screen to operate vacuum piston (CAUTION—do not remove screen). Then proceed as follows:
1)—Close throttle, press vacuum piston in as far as possible, open throttle and hold it open while completing steps 2) and 3). Remove wire (slide will drop down into shallow groove in piston and hold piston in as long as throttle is held open).
2)—Rotate fast idle cam to cold or fast idle position, place 5/64" spacer between throttle stopscrew and fast idle cam, close throttle sufficiently so that spacer is gripped between screw and cam. Turn ignition on, hold spacer in position by hand and open throttle. Starter should not crank engine. If starter does operate, see 4) for adjustment but do not make adjustments until after making test 3).
3)—Use a 3/64" spacer and repeat test procedure given in 2) above. Starter should crank engine. If starter does not operate, adjust as follows:
4)—Adjust by bending tang on operating lever on throttle valve shaft which contacts switch slide. Bend tang downward if starter cranks during test 2) above (with 5/64" spacer), bend tang upward if starter does not crank during test 3) above (with 3/64" spacer). *CAUTION—Bend tang only slight amount and repeat tests 2) and 3) until correct operation secured.*

Approximate Switch Timing (with carburetor off engine): Close throttle valve on a drill rod of correct size (see table below) placed between throttle valve edge and carburetor wall. Bend tang on operating lever until it just contacts switch slide.

▷*CAUTION—This approximate setting must be checked and readjusted after carburetor installed on engine.*

Throttle Opening (Approx. Switch Setting)

	Throttle Opening	Drill Rod
Series 40, 50 ('48-49)	.075-.085"	#45 to #43
Series 70 ('48-49)	.080-.100"	#39 to #42
Series 40 ('50-53)	.086-.096"	#43
Series 50 ('50-52)	.086-.096"	#43
Series 70 ('50-52)	.090-.100"	#41
Series 50 ('53)	.110-.120"	#34
Series 70 ('53)	100-.110"	#37

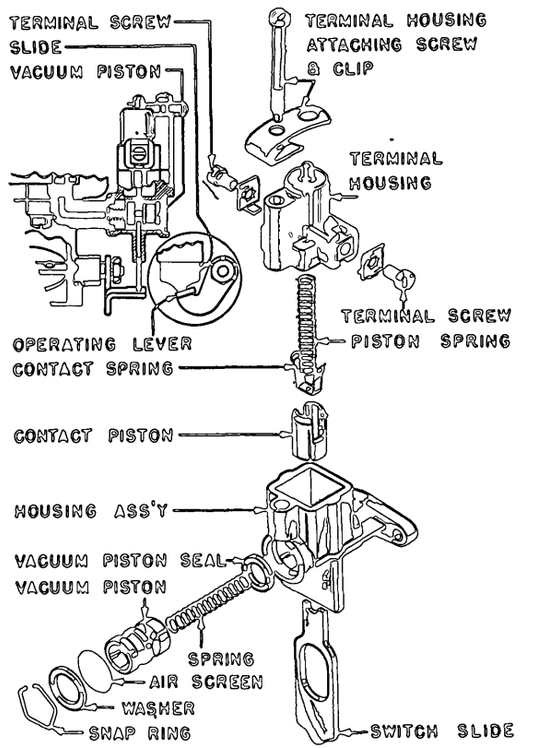
LUBRICATION: No lubrication is required in service. If switch has been disassembled, lubricate inside surface of terminal cap lightly with Beacon M-225 lubricant (Stromberg 385093) applied sparingly.

▷*CAUTION—Do not use other lubricant than specified above and DO NOT LUBRICATE SLIDE OR PISTON.*

DISASSEMBLY: Remove switch from carburetor by taking out two mounting screws. Remove terminal cap screw and clip, lift off cap and spring. Remove vacuum piston screen clip, remove washer and screen, move switch slide so that it does not interfere with piston, withdraw piston and piston spring.

▷*CAUTION—Do not interchange vacuum piston and switch contact guide springs (contact guide spring is HEAVIER).*

REASSEMBLY: Reverse disassembly directions given above and note the following important points:



Vacuum Piston—Install with end having deep groove and tapered counterbore inward (toward seal). Piston spring must not be interchanged with contact guide spring (piston spring is LIGHTER).

Contact Spring—Use extreme care not to distort or change dimensions of spring (will affect switch operation). Contact width should be 9/16" over-all (outside to outside of spring at open end). Contact guide spring must not be interchanged with vacuum piston spring (contact guide spring is HEAVIER).

Switch Slide—Narrow projection on top of slide must enter slot in bottom of contact guide.

Mounting Gasket—Always use NEW gasket on mounting flange to insure vacuum-tight seal (vacuum passage terminates at port in flange).

▷*CAUTION—Switch will not operate satisfactorily if this vacuum channel is not open or if atmospheric leak exists at mounting flange.*

STROMBERG STARTER SWITCH

①—Stromberg No. 384476 Kick-down Switch unit (separate unit).

►CHANGES, CAUTIONS, CORRECTIONS

►**Carter Kick-down Switch Parts Change (for Improved Performance):** Set of switch parts for improved operation furnished by Carter as Unitized Package No. 195-47U and should be used when reconditioning above Carter carburetors (except E7L4 and later carburetors).

Unitized Package No. 195-47U

Part No.	Part No.
63-98 Switch Piston Locator.	160-88S Switch Piston.
86-40 Terminal Washer.	184-53S Terminal Block Assy.
115-98U Pushrod Assy. & Spring.	101-36 Terminal Screw.

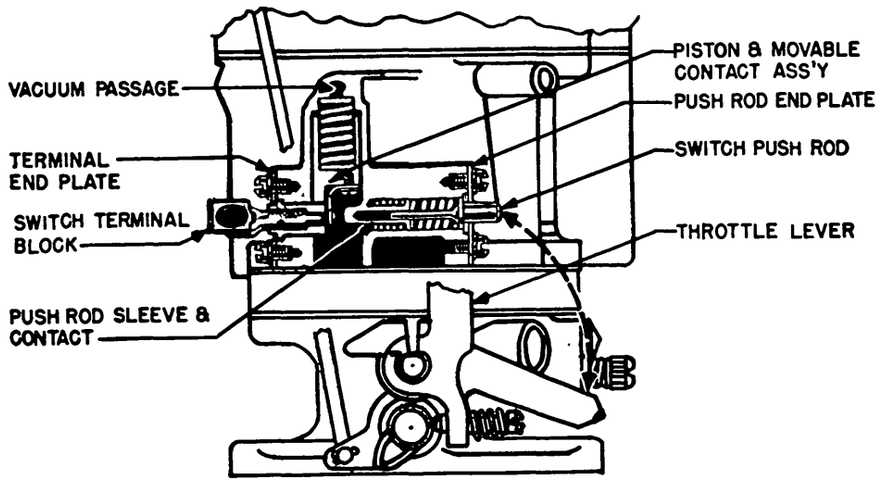
►**1949 Dodge Kick-down Switch Change for Improved Transmission Performance (Carter D6M1 & Stromberg BXVES-3 Code 3-95 & 3-95A Carburetors):** New kick-down switch springs furnished which raise kick-down speed limit from 40 to 43 MPH. **Carter and Stromberg spring not interchangeable** but can be identified as follows:

Carter—No. 61-399 (Dodge 1320082). Wire diameter .400", marked by blue dye (Stromberg spring also blue but lighter wire).

Stromberg—No. 385162 (Dodge 1320081). Wire diameter .350", marked by blue dye (Carter spring also blue but heavier wire). Spring free length 1 5/16". **This spring used in production on Code 3-95B carburetors.**

►*CODE 3-95C & LATER CARBURETOR CAUTION*—These carburetors have new type uncolored spring (free length 1⅜") and **should not be changed.**

DESCRIPTION & OPERATION: This unit is built-in carburetor (except Stromberg AAVS-2 which is mounted on the carburetor) for transmission control. It consists of a stationary contact connected to the transmission control solenoid, a movable contact mounted on a vacuum piston, and a switch plunger operated by the carburetor throttle valve lever which completes the circuit to ground (energizing the transmission solenoid) when the throttle valve is opened to slightly less than wide-open position. This action occurs at car speeds under approximately 27 MPH. (Low Range—for kick-down to First Gear), 53 MPH. (High Range—for kick-down to Third Gear). At higher car speeds, manifold vacuum pulls piston and movable contact up out of engagement so that plunger does not complete circuit to ground and kick-down does not occur.



NOTE—Speeds listed above apply to Vacamatic and Simplimatic Transmissions. On hydraulically controlled transmissions, kick-down limit speeds are 40-45 MPH. (Chrysler), 38-40 MPH (De Soto) in High Range. Low Range limits are correspondingly lower.

DISASSEMBLY: To disassemble, remove two screws in switch plunger end plate and withdraw plunger. Insert small soft drift into vacuum chamber to hold vacuum piston in position against spring tension, then remove two screws in stationary contact end plate, remove end plate and contact assembly. Release pressure on vacuum piston, remove piston and spring. Movable contact can be removed by taking out mounting screw in end of piston. Clean all metal parts thoroughly, examine entire assembly for damage or wear. Reassemble switch.

REASSEMBLY CAUTION—See switch change notes (preceding) for switch parts change to improve switch operation and transmission performance.

Stromberg AAVS-2 Switch Mounting Note—Vacuum passage and air passage for switch operation terminate at holes in switch mounting flange. Make certain that these passages are clean and that air-tight joint secured when switch assembly mounted on carburetor (use special mounting gasket Stromberg No. 384468).

ADJUSTMENT: Stromberg BXVES-3 Kick-down Switch—Adjust by bending tang or ear on throttle lever which contacts switch plunger so that plunger travel is 5/32" minimum when throttle valve is in wide open position. Plunger must have a minimum of 1/64" over-travel in this position.

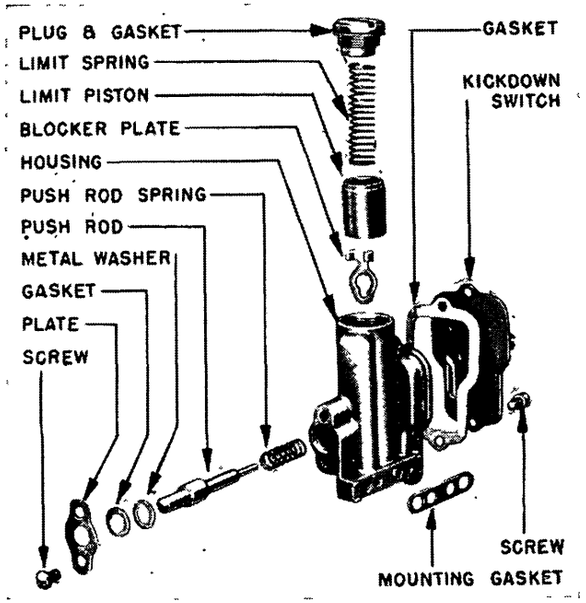
CARTER (B&B) KICK-DOWN SWITCH (STROMBERG BXVES-3 SIMILAR)

CHRYSLER, DE SOTO, DODGE V8 KICK-DOWN SWITCH

CHRYSLER & DE SOTO V8 (WITH CARTER "WCD" CARBURETOR)

Car Model	Kick-down Switch No.
Chrysler V8 (1951-53)	Carter No. 170-194S
DeSoto V8 (1952) ①	Carter No. 170-194S

①—Carter "WCD" Carburetors.



►*SWITCH NOTE: This switch has "Snap Action" type switch assembly mounted on side of housing.*

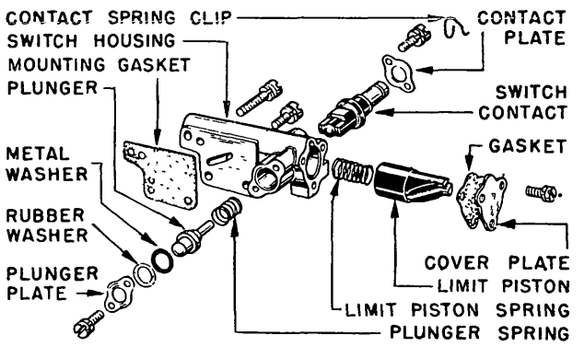
DESCRIPTION & OPERATION: Unit is mounted on carburetor throttle body and is vacuum controlled by a limit piston and blocker plate assembly. Switch can be operated only below 40 to 45 MPH. with wide open throttle. Above this speed, vacuum in main venturi moves the piston and blocker plate up, thus limiting travel of plunger so that snap action switch cannot be operated.

TROUBLE SHOOTING: If switch does not operate correctly, make following tests:

1) Disconnect wire at switch terminal, connect a 6 volt test lamp between this terminal and the negative terminal of the battery. Slowly push plunger in and listen for "click" of switch as it snaps to closed position. **Test lamp should light at same instant "click" is heard.** If lamp does not light, or considerable additional pressure required to light the lamp, switch is defective and should be replaced. If no "click" is heard and plunger travel is limited, piston and blocker plate are probably stuck in upper position and switch should be disassembled and cleaned.

2) If switch operates properly in test (1) above, operate switch by pressing accelerator pedal. Switch should click and test lamp light just before pedal reaches full travel. If excessive pressure (and compression of floor mat) required to operate switch, readjust throttle linkage, repeat test.

CHRYSLER & DE SOT V8 KICKDOWN SWITCH (WITH CARTER "WCD" CARBURETOR)



DISASSEMBLY: Remove kickdown push rod plate screws, lift out push rod, spring, metal washer, gasket, and plate as a unit. Remove limit piston plug and gasket from top of unit, lift out limit spring, piston and blocker plate *(NOTE*—Check piston for sticking before removal). Remove switch cover attaching screws, lift off switch assembly and gasket.

Cleaning & Inspection: Clean parts by immersing in solvent, dry with compressed air, inspect all parts for wear or damage. Check limit piston by installing piston and plug (omit spring), shake housing to make certain piston slides back and forth freely.

REASSEMBLY: Reverse disassembly procedure given above using new gaskets. When mounting unit on carburetor, blow out vacuum and vent passages in throttle body, use new switch mounting gasket and tighten mounting screws securely. Test switch as follows:

TESTING (After Installation): Connect 6 volt test lamp between switch terminal and negative side of battery. Slowly push plunger in, listening for the "click" of the switch and noting that lamp lights at same instant the "click" is heard.

Road Test of Switch Action—Check car on road to make certain switch operates below 45 MPH. but does not operate above 45 MPH. Test at 40, 45, and 50 MPH. by accelerating at ¾ throttle and pushing accelerator pedal down to kick-down position at speeds noted.

DODGE & DE SOTO V8 KICKDOWN SWITCH (DE SOTO WITH CARTER "BBD" CARBURETOR)

DODGE V8 & DE SOTO (WITH CARTER "BBD" CARBURETOR)

Car Model	Kick-down Switch No.
DeSoto V8 (1952-53) ②	Carter No. 170-231S
Dodge V8 (1953)	Stromberg No. 386190

②—Carter "BBD" Carburetors.

DESCRIPTION & OPERATION: Switch assembly is a separate unit mounted on the carburetor main body (vacuum and vent passages extend through switch mounting flange). Switch consists of a stationary contact or terminal and a movable contact located in the end of the limit piston. At car speeds below 45 MPH., these two contacts are aligned and the switch is closed by a spring-loaded plunger actuated by the throttle lever. At car speeds above 45 MPH., vacuum at carburetor main venturi is sufficient to pull limit piston in against spring tension, withdrawing the movable contact so that the plunger does not make contact.

TROUBLE SHOOTING: If switch does not operate correctly, make the following tests:

1) Disconnect wire at switch terminal, connect a 6 volt test lamp between this terminal and the negative terminal of the battery. Slowly push plunger in. Lamp should light. If lamp does not light with full plunger travel, limit piston may be stuck in inner position or contacts are dirty. Disassemble and clean switch.

2) If switch operates properly in test (1) above, operate switch by pressing accelerator pedal. Test lamp should light just before pedal reaches full travel. If lamp does not light, or if excessive pedal pressure required, readjust throttle linkage and repeat test.

3) Check car performance. See Testing (after Installation) below.

DISASSEMBLY: Remove plunger plate screws, lift out plate, washers, plunger, and spring as a unit. Remove switch contact plate screws, lift out terminal plate and contact. On DeSoto, unscrew limit piston plug; on Dodge, remove screws and lift off limit piston plate and gasket. Slide limit piston and spring out of cylinder.

Cleaning & Inspection: Clean parts by immersing in solvent, dry with compressed air. Inspect all parts for wear or damage. Check limit piston by installing piston in cylinder (without spring) and shaking housing with thumb held over opening. Piston should slide back and forth freely.

REASSEMBLY: Reverse disassembly procedure given above. Make certain that contact in limit piston faces toward fixed contact opening and that limit piston moves freely **after** terminal and contact assembly installed. When mounting unit on carburetor, use NEW switch mounting gasket and make certain mounting face on switch and carburetor are clean, tighten mounting screws securely. Test switch as follows:

TESTING (After Installation): Check switch performance as directed in tests (1) and (2) in TROUBLE SHOOTING above. Road test car as follows:

Road Test of Switch Action—Check car on road to make certain that switch operates below 40 MPH. but does not operate above 45 MPH. Test at 40, 45, and at 50 MPH. by accelerating car at ¾ throttle and pressing accelerator pedal down to kick-down position at speeds noted.

HYDRAULIC BRAKE TROUBLE SHOOTING

Brake Pedal goes down to the floor:

1. Master cylinder empty. Refill and check for leaks in the brake system. If cylinder is completely dry it will be necessary to bleed the entire system, to remove air. After refilling and bleeding, apply the brakes and if pedal still goes down check for bad fluid leak. Examine bottom of each brake drum for fluid drip which would indicate a leaking wheel cylinder. Also look under car for leakage on floor from line leak, or from master cylinder (at boot), indicating worn master cylinder parts. If pedal action normal make further check for leakage by depressing pedal hard and holding it down for 2 or 3 minutes. After a minute or so it may start to go down slowly indicating a leak. NOTE—Pedal going down slowly can also be caused by a worn master cylinder cup allowing leakage past the piston. This would not cause an external leak as fluid would return to the master cylinder reservoir, through the intake port.
2. Excessive lining to drum clearance.
3. Air in the brake system.

Too Much Pedal Travel Before Brakes Are Applied (with Brakes Adjusted and Bled):—

1. Defective master cylinder check valve. Master cylinder check valve is designed to maintain 8 to 10 lbs. pressure on the brake system when brakes are released. If pressure is not maintained considerable pedal movement is used to develop line pressure before brakes operate.
2. Too much clearance between pedal rod and master cylinder.

One Wheel Locks When Brakes Are Applied:—

1. Grease, oil, or brake fluid on lining. NOTE—If lining is saturated with oil or fluid it should be replaced.
2. Improperly adjusted shoes.
3. Brake shoes installed incorrectly.
4. Brake shoe springs installed incorrectly.

Brakes Drag or do Not Release Properly:—

1. Improperly adjusted brake shoes.
2. Broken shoe return spring.
3. Wheel cylinder piston frozen.
4. Mineral oil in the brake system. This oil will cause rubber cups to swell up causing sluggish action. NOTE—When mineral oil is found in brake system, the wheel cylinders and master cylinder should be reconditioned, and the lines thoroughly flushed out with alcohol, or new fluid.
5. Master cylinder by-pass port plugged, or pedal to master cylinder rod not adjusted correctly, not allowing the master cylinder piston to return far enough to uncover the by-pass port. See Pedal Adjustment instructions for the particular car being repaired.

Brakes Go On By Themselves (locking all wheels) while driving:—

1. Condition shown in item 5 under "Brakes drag or do not release properly" apply to this trouble.

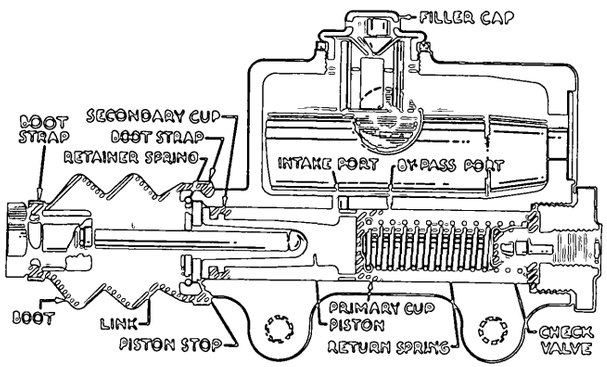
Car Pulls To One Side:—

1. Improper brake shoe adjustment.
2. Grease or oil on lining of one brake.
3. Plugged brake hose making one brake inoperative.

Brake Pedal Springy:—

1—Air in system. Bleed lines.
2. Brake shoe anchors incorrectly adjusted.
3. Thin brake drums, caused by machining too large oversize.

Brake Pedal 'Hard':—



1—Improper adjustment.
2—Incorrect lining type.
3—Oily linings—replace or install new shoes.
4—Partial contact—high spots. Linings should be ground concentrically.

SERVICING NOTE:—See following article for directions for bleeding lines and servicing of master and wheel cylinders. See separate brake articles for brake shoe and brake pedal adjustment directions.

HYDRAULIC BRAKE SERVICING

BLEEDING BRAKE LINES:—Remove master cylinder supply tank filler cap, fill tank with genuine brake fluid, keep tank filled with fluid during entire bleeding operation (air will be drawn into brake lines if tank allowed to become dry). Remove screw in bleeder valve on wheel backing plate, install special fitting and hose connection. Submerge free end of hose in brake fluid in clean glass container. Unscrew bleeder valve ½-¾ turn, press brake pedal down by hand approximately half of travel, allow pedal to return slowly. Repeat operation until fluid flow from tube is completely free from any air bubbles, then close bleeder valve, remove hose connection and replace dustscrew. Bleed lines at each wheel in same manner.

CAUTION—Use extreme care not to allow supply tank to become dry during bleeding operation. If automatic refiller unit not used, supply tank should be filled after every 6-10 strokes of the brake pedal (automatic refiller will maintain level in supply tank without attention during bleeding operation).

DRAKE MASTER CYLINDER

Two Cylinder (Chrysler Type Front Wheel Brake). When bleeding these brakes, first attach bleeder line to lower cylinder bleeder connection, bleed this cylinder and the brake line as directed above. Then connect bleeder line to upper cylinder bleeder connection and bleed this cylinder and the line between the cylinders as directed above. Both cylinders must be bled in this manner to remove all air from the brake system.

Chrysler Disc Type. Bleed all four lower cylinders first, and then four upper cylinders. See Disc Type Brake for complete information.

Brakes with Power Units (Hydrovac, Midland, Vacdraulic, Vacu-Ease). See separate articles on these units for information about bleeding.

SERVICING:—Wheel Cylinders—To disassemble wheel cylinders, remove brake shoes, take out wheel cylinder mounting screws, withdraw cylinder through backing plate. Disconnect brake line, remove piston boots, withdraw pistons. Examine cylinder bore. If corroded or scored, cylinders can be lapped or honed and oversize pistons fitted. Piston clearance (metal piston) in cylinder should be .001-.003" and must never exceed .005". In assembling wheel cylinder, wash all parts in alcohol, dip rubber piston cups in Brake Fluid, and insert ahead of piston with lip in. Central return spring in stepped cylinders is tapered and should be installed with small end toward piston in smaller bore. Reconditioned cylinders should be tested for leakage in fixture under alcohol with 8 lbs. and 80 lbs. air pressure. Wheel must be bled when wheel cylinder reinstalled.

Piston Cup Expanders—Can be used with special return spring in wheel cylinders to correct leakage caused by piston cup contraction in extreme cold temperatures. Expander should have .005" clearance in cylinder and should fit into open end of piston cup with slight clearance. Install expanders with cupped face in and use special return spring which is ½ turn shorter than standard spring.

Chrysler Wheel Cylinder Pistons (with Rubber "Piston Ring"). On all Chrysler, DeSoto, Dodge, Plymouth separate piston cups are not used and the pistons are sealed by a rubber piston ring in a groove on the pistons. These piston rings are removed by rolling them off the end of the piston. Install piston rings with lip in toward inner end of cylinder. On two cylinder brakes (with single acting pistons), install piston spring with large end toward piston and smaller end in toward end of cylinder.

Master Cylinder:—To disassemble master cylinder, remove rubber boot and push rod or link, take out retainer spring and piston stop, withdraw piston. Examine cylinder. If corroded or scored, cylinder can be lapped or honed and oversize piston fitted. Clearance should be .001-.003". In reassembling, wash all parts in alcohol, dip in Brake Fluid, see that check valve is installed correctly and that thin washer is in place between piston and primary piston cup. Insert piston with lips on both primary and secondary cups in. Test for leaks in same manner as for wheel cylinders and bleed entire system when installed on car.

By-pass Port Note—By-pass or compensating port connecting supply tank and master cylinder must be uncovered with the master cylinder piston against its stop. When installing master cylinder piston assembly, hold piston against stop and make certain that this port is not covered by lip of primary cup.

CAUTION—When master cylinder installed on car, brake pedal must be adjusted for correct pedal clearance or free-travel to insure this by-pass port being uncovered with pedal released and master cylinder piston against its stop. Brakes will drag if this port is not open.

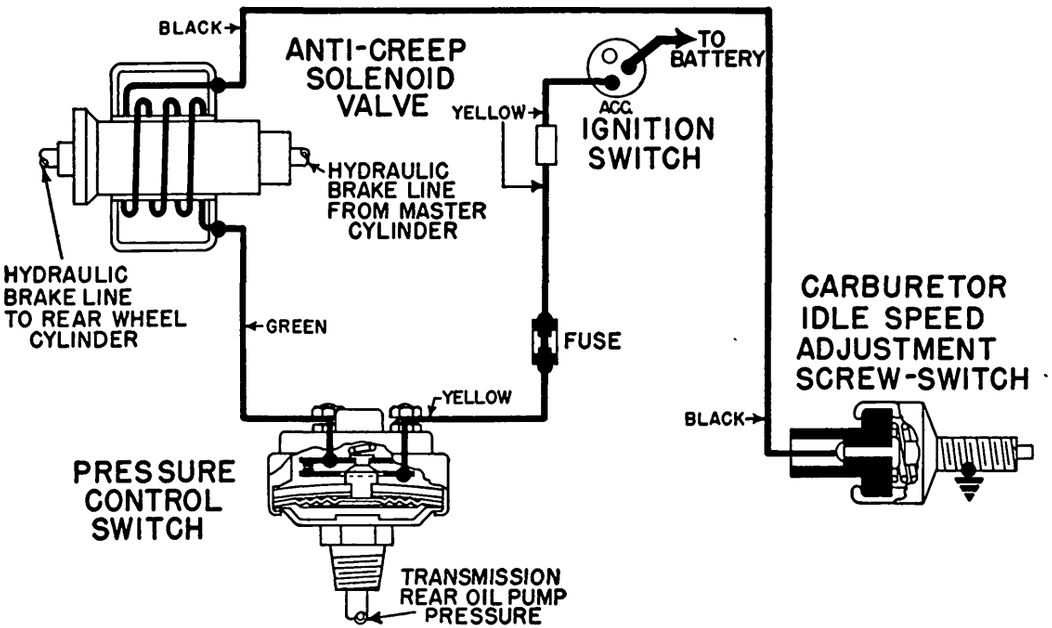
ANTI-CREEP

Studebaker 1950-55 Models with Auto. Trans.

►**ANTI-CREEP RELEASE SWITCH NOTE:** On 1950 Commander models, this switch also controls the engine idle speed and is called the "Carburetor Idle Speed Adjustment Screw Switch" (see illustration). On other models, switch is mounted as follows:

Champion—Release switch is mounted on accelerator cross shaft bracket on dash. Switch contacts are closed by the cross shaft lever when accelerator pedal is released (closed throttle), and open when the accelerator pedal is depressed to open the carburetor throttle.

1950 Commander—Release Switch or "Carburetor Idle Speed Adjustment Screw Switch" mounted on carburetor throttle lever and replaces the customary throttle idle speed stopscrew. When accelerator pedal is released, switch contacts are closed and the switch also positions the throttle valve for correct engine idle speed. When the accelerator pedal is depressed to open the carburetor throttle, the switch contacts open.



1951 & Later Commander & President—The release switch is mounted on accelerator cross-shaft bracket on dash (similar to Champion).

DESCRIPTION: System comprises a solenoid valve, pressure control switch and a release switch (see 1950 Commander data above). With ignition on, or when engine is idling and the car is not in motion and brakes are applied, the rear brakes will remain on, after releasing brake pedal, until accelerator is again depressed. With car in motion, system is inoperative and brakes function normally.

OPERATION: The solenoid valve mounted on rear of master cylinder holds brake pressure on the rear brakes whenever the Anti-Creep circuit is closed. The pressure control switch which is operated by automatic transmission rear pump pressure, opens the Anti-Creep circuit when the car is moving forward, and closes the circuit when the car is stationary, or moving in reverse. The release switch opens or closes the circuit as the accelerator is depressed or released. With the ignition "on", the accelerator released (release switch closed), and the car stationary (pressure control switch closed), the Anti-creep circuit is completed through these switches and the solenoid valve is energized. When the brakes are applied under these conditions, the anti-creep solenoid valve will retain approximately 200 pounds per square inch pressure at the rear wheel brakes to prevent "creeping." When the accelerator pedal is depressed, the circuit is open at the idle adjusting screw switch allowing the solenoid to de-energize thereby releasing the brakes instantly. When the car is moving forward, normal brake operation is not affected since the rear pump pressure holds open the Anti-Creep pressure control switch, preventing solenoid from energizing.

CONTROL UNITS REMOVAL & INSTALLATION: If operation not satisfactory and checking indicates units defective, remove and replace as follows:

Release Switch: To remove switch, disconnect switch lead, loosen locknut and unscrew switch from bracket (carburetor throttle lever on 1950 Commander).

ANTI-CREEP CONTROL UNIT WIRING DIAGRAM

►***CAUTION—Switch must be adjusted when re-installed on car.***

Pressure Control Switch—To remove, disconnect switch leads, unscrew switch from transmission case.

Solenoid Valve: To remove, disconnect all leads, disconnect brake line at solenoid valve outlet. Take out screw mounting solenoid valve on adapter, lift unit out. Install solenoid valve in same manner.

►***CAUTION—Bleed brakes after installing solenoid valve and connecting brake line.***

ADJUSTMENT: Release switch is only point requiring adjustment. Adjust switch, for each model, as follows:

1950 Commander Carburetor Idle Speed Adjustment Switch—Switch also controls engine idle speed and must be adjusted only with engine warm. With engine warmed up (choke valve wide open, fast idle inoperative), disconnect wire at switch on carburetor throttle lever, place selector lever in Neutral "N" position, turn switch in or out of carburetor lever until engine speed is 500-550 RPM.

Champion (All Models), Commander (1951-52)—After transmission linkage adjustment is completed, loosen switch locknut and screw switch into bracket until switch plunger just contacts plate. Connect switch wire, turn on ignition, screw switch in until an audible click is heard in the anti-creep solenoid. Tighten switch locknut.

Commander (1953 & Later), President—After carburetor and transmission linkage adjustments are completed, turn release switch into cross-shaft bracket until carburetor idle adjustment screw starts to break with low step of fast idle cam. Back off the anti-creep release switch three complete turns and secure with locknut. Install wire and test operation.

Linkage Adjustment: *See "Studebaker" Automatic Transmission in Transmission Section.*

CHECKING OPERATION: 1) While driving car at approximately 10 MPH, selector lever in "D" position, quickly apply and immediately release brakes. **Do not touch accelerator pedal.** Car should roll freely with no evidence of brake drag after brake pedal is released.

2) While driving car on level ground, release accelerator pedal and apply brakes, bringing car to complete stop. Car should not creep forward until accelerator pedal is depressed.

3) With car standing on level ground and engine idling, selector lever in one of "D" positions, and with anti-creep system preventing car from creeping, touch accelerator pedal lightly, then release it. Car should creep slowly from a standstill.

TROUBLE SHOOTING: Anti-Creep System Inoperative—Carburetor throttle valve sticking slightly open; release switch incorrectly adjusted; release switch sticking open; system fuse burned out; open circuit in ignition switch; open circuit between fuse and ignition switch; open circuit between pressure switch and fuse; pressure switch sticking open; open circuit between solenoid valve and pressure switch; open circuit or ground in coil winding of solenoid valve; open circuit betwen solenoid valve and release switch; check valves or gaskets allowing front pump pressure in rear pump line.

BENDIX POWER UNIT

Chevrolet Passenger Cars (1954-55)
Hudson (1955)
Lincoln (1953-55)
Mercury (1953-55)
Nash, Ambassador & Statesman (1954-55)
Oldsmobile (1953-55)①
Packard (1953-55)
Pontiac (1954-55)①

①—Moraine Brake Power Unit also used in 1955.

►CHANGES, CAUTIONS, CORRECTIONS

►*1953 LINCOLN & MERCURY BRAKE PEDAL TRAVEL CAUTION:* A minimum of 1" (Lincoln), 1½" (Mercury) pedal to floor clearance must be maintained (engine running). If less, check brake adjustment and need for new brake linings.

►*1953 EXHAUSTION OF VACUUM SUPPLY CAUTION (Engine Stalled):* It is possible to exhaust vacuum supply with two applications of brake (engine stalled). *(NOTE–See Oldsmobile Production Change below).* With no vacuum assist pedal pressure required to stop vehicle is greatly increased. If engine stalls (or is parked) on steep grades, stop car completely, set hand brake firmly, turn off ignition, and place selector lever in "R" position. Before releasing hand brake be sure engine is running.

►*1953 OLDSMOBILE SOLENOID VALVE ADDITION & VACUUM RESERVE TANK PRODUCTION CHANGE:* A solenoid valve, mounted on top of an enlarged vacuum reserve tank, has been added to Power Brake Unit of late 1953 cars. Solenoid is connected into stoplight switch energized power assist to brakes is available and will permit 3 or 4 brake applications with engine off or stalled at coasting speeds below 20 MPH. **Oldsmobile Solenoid Valve Checking and Adjustment–** With transmission in neutral and engine stopped, coast 20-30 MPH and apply brakes. Brake operation should be smooth and the same as with engine running. If there is any catch or hard spot in pedal travel, the stop light switch should be adjusted as follows: Loosen stop light switch attaching screws, then adjust switch so that stop lights make contact with first 1/8"-1/4" of pedal travel. Tighten attaching screws, again check to be certain that stop lights go off when brake pedal is in fully released position. Re-check operation by coasting and applying brakes.

►*1953-54 LINCOLN & MERCURY BRAKE MASTER CYLINDER OPERATING LEVER BRACKET INSTALLATION CAUTION:* When installing Lever Bracket, Part No. LA-22519-A., into pedal support brace, it is necessary to install lower retaining bolts with head of bolt to inside of pedal support, with nut and lockwasher installed on outside. If installation made with nut to **inside** of pedal support, full travel of brake pedal will be restricted.

►*1955 CHEVROLET BRAKE BLEEDING CAUTION (To Prevent Trapping Air in System):* Since no bleeder is provided at forward end of power unit to permit trapped air to escape from forward end of unit (due to slight tilting above horizontal line from pushrod eye for design reasons) one of two following methods can be used to eliminate any air trapped in system:

Unit Off Car: Fill master cylinder approximately half full, with forward end of unit tilted down below a horizontal line from pushrod eye, before unit is installed in position on dash panel.

Unit On Car: Raise rear end of car until forward end of power unit is tilted below a horizontal line from pushrod eye.

►*1955 CHEVROLET SLOW BRAKE PEDAL RETURN CORRECTION:* Check to see that pushrod has been installed to **inboard** side of lever assembly at the pedal linkage instead of to outboard side; check rubber boot to see that bellows have been pulled through smaller hole in dash panel and mounting plate (This should be done at same time power unit is being assembled to mounting plate) and that bellows are not all gathered on front side of dash panel and mounting plate, causing bind on pushrod; check lubrication at pedal linkage. Lubriplate where necessary. On early cars, after checking as indicated above, and brake pedal return is still slow, remove power unit from front of dash. Remove rubber boot, and squirt some rubber lubricant between valve sleeve into which pushrod is assembled and sleeve bore in valve assembly (This will lubricate "O" ring seal in valve sleeve).

►*1955 CHEVROLET VACUUM LEAK CAUTION (Windshield Washer Installation):* Some V-8 engine cars equipped with power brakes and electric windshield wipers (early cars) did not have proper Tee connection at carburetor for washer installation. When washer being installed be sure proper fitting is in carburetor. If not, install Tee Part No. 3718911 to make washer connection. **Under no circumstances cut into power brake line at any point.**

DESCRIPTION: Self-contained hydraulic vacuum power braking device utilizing engine intake manifold vacuum and atmospheric pressure for its power. It consists of three separate units as follows:

Power Unit: Three elements are combined to make up this single unit, namely:

(1) Vacuum Power Cylinder comprising a cylinder power piston, and piston return spring.

(2) Hydraulic Master Cylinder containing an hydraulic plunger, compensating valve, residual check valve, and fluid reservoir.

(3) Control Valve, mechanically actuated, which controls degree of brake application or release in accordance with foot pressure applied to pedal.

Vacuum Reserve Tank provides vacuum assist for a limited time when engine stalls.

Manifold Check Valve, in vacuum source line, maintains vacuum in unit should engine stall.

OPERATION: With engine running, brakes unapplied, both sides of power piston are open to atomspheric pressure. Application of the brake pedal causes vacuum port to open, thus connecting the forward side of vacuum power piston and rear side of reaction diaphragm to engine vacuum. This pressure differential causes power piston to move forward, thereby exerting a thrust on the hydraulic plunger. This increases line pressure to the four wheels. Release of the brake pedal restores the pressure balance in the power cylinder.

CHECKING & ADJUSTMENT: Check all parts of the power brake system before disassembling the Power Brake Unit whenever brake trouble experienced.

Adjustments: None required. If unit becomes faulty, manufacturer recommends that unit be overhauled using Power Brake Repair Kit. *NOTE*–Use all parts in kit. *DISCARD ALL OLD RUBBER PARTS.*

Bleeding Brakes: Bleed in same manner as standard brake system. Do not use vacuum assist while bleeding. Engine should not be running and vacuum reserve should be reduced to zero by applying the brake several times before starting bleeding.

Air Cleaner: Clean twice a year. To clean, remove air cleaner and thoroughly wash in cleaning solvent. Allow cleaner to dry before reinstalling.

Refilling Fluid Reservoir: Check level every 1000 miles. If level not up to "L" mark on dipstick (Oldsmobile); ¼" from filler plug opening (Lincoln & Mercury), within ½" from filler plug opening (Others), add brake fluid.

Vacuum & Hydraulic Line Inspection: Every 5000 miles, check hose, tubing and connections. Replace deteriorated hose or damaged tubing.

TESTING: Road test brakes by making a brake application at about 20 MPH to determine if vehicle stops evenly and quickly. If pedal has a spongy feel when applying brakes, air may be present in hydraulic system. Bleed system as described above. When engine is stopped and transmission is in neutral, apply brakes several times to remove all vacuum in system. Depress brake pedal, hold light foot pressure on pedal and start engine. If vacuum system is operating, pedal will tend to fall away under foot pressure, and less pressure will be required to hold pedal in applied position. If no action is felt, vacuum system is not functioning. Stop engine and again remove all vacuum in system. Depress brake pedal and hold foot pressure on pedal. If pedal gradually falls away under foot pressure, hydraulic system is leaking. If brake pedal travels to within 1" of toeboard, brake shoes require adjustment or relining.

LUBRICATION: Piston packing seal is lubricated at time of assembly and requires no further lubrication *CAUTION–NEVER lubricate vacuum valve.*

TROUBLE SHOOTING: The following conditions apply to Power Brake operation. Be sure brake shoes, drums, linkage, and adjustments correct before repair of Power Brake System.

Hard Pedal: Vacuum failure due to faulty vacuum check valve, collapsed vacuum hose, plugged vacuum hose or fittings, leaking vacuum reservoir or vacuum hose and pipe connections; bound up pedal mechanism; glazed linings; grease, brake fluid, or water on linings; vacuum leak in unit between piston plates, past leather piston packing, between vacuum cylinder and master cylinder, or around hydraulic plunger seal; restricted air cleaner; jammed pushrod and valve plunger; broken counter-reaction spring; leak past atmospheric poppet; vacuum hose on piston loose or restricted.

"Grabby" or Severe Brakes: Grease or brake fluid on linings; scored drums; anchor pins loose; vacuum leak in the reaction diaphragm; sticking pushrod and valve

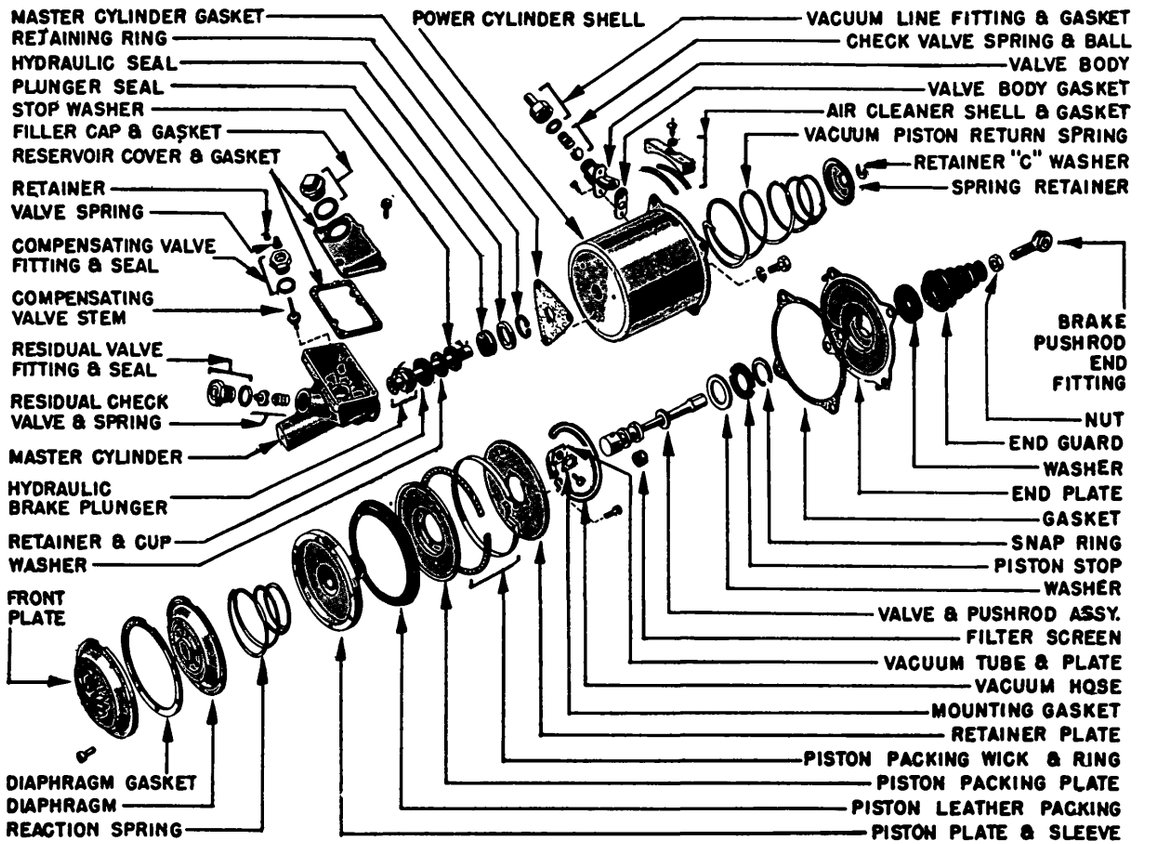
CONTINUED ON NEXT PAGE

BENDIX POWER UNIT (C nt.)

plunger; faulty pivot arm and vacuum poppet action; restricted diaphragm passage.

P dal Goes To Floor (Or Almost To Floor): Brakes require adjustment; air in hydraulic system; hydraulic leak in lines or at wheel cylinders; fluid reservoir needs replenishing; cracked drums or broken linings; hydraulic leakage at compensating valve, hydraulic plunger seal, compensating seal or outlet fitting seals.

Brakes Fail To Release (Or Slow Release): Anchor pins loose; bound up brake pedal linkage; brakes improperly adjusted; faulty residual check valve; excessive hydraulic plunger seal friction; faulty compensating valve; excessive piston packing friction; restricted air passage in piston plate; restricted air cleaner; sticky pushrod and valve plunger; broken piston return spring.



REMOVAL (CHEVROLET): From engine side of dash panel remove vacuum lines from vacuum inlet tube on intake manifold (top of engine on V8, left side center on 6 Cyl.). Remove vacuum line to vacuum reservoir. Remove stop light wire connection. Remove hydraulic line from hydraulic cylinder. From inside body remove lever to pushrod retaining bolt washer, lockwasher and nut and disengage pushrod from pushrod lever. Remove bolts and lockwashers retaining power brake unit to dash unit and remove unit from vehicle.

REMOVAL (LINCOLN & MERCURY): Disconnect pushrod from brake pedal. Remove master cylinder outlet fitting bolt (NOTE—It is not necessary to remove stop light switch wire or hose assembly from outlet fitting). Do not disturb outlet fitting in master cylinder. Loosen manifold hose clamp at check valve, remove hose from valve. Loosen vacuum reserve tank hose clamp at check valve and remove hose from valve. Remove bolts securing power brake assembly to bracket on dash panel, remove assembly.

REMOVAL (OLDSMOBILE): Disconnect hydraulic line at power brake master cylinder. Use care to prevent dirt entering hydraulic line and secure hose so that open end is above level of junction assembly to prevent loss of fluid. Plug master cylinder outlet with rubber stopper. Disconnect leads from stoplight switch and fold back floor mat. Remove three brake pedal bracket attaching bolts. Remove bracket and pedal assembly. Remove mast jacket grommet retainer clip and slide grommet up mast jacket. Remove mast jacket cover plate attaching screws. Loosen speedometer cable hold down clip and slip cable from under clip, then remove speedometer cable and grommet from mast jacket cover plate. Remove two cover plate to power cylinder bolts, and remove cover plate while positioning power brake unit so it rests on edge of opening in toe pan. Disconnect vacuum hoses and remove power brake unit through toe pan opening.

►*INSTALLATION NOTE:* When reinstalling hoses, position clamps so screw heads may be reached from below car. Place 5/16" bead of 3M Sealer around entire toe pan groove.

REMOVAL (PACKARD): Disconnect vacuum, atmospheric, and hydraulic lines and stoplight wires from power unit (raise hydraulic line above level of junction assembly to prevent fluid leakage). Disconnect and remove brake and accelerator pedals. Remove steering column grommet retainers, slide grommet up out of way. Remove carpet retainers and fold back carpet. Remove cover plate screws, then remove power brake and cover as an assembly, take out mounting screws and remove power brake from cover.

1953-54 BENDIX BRAKE POWER UNIT

REMOVAL (PONTIAC): Disconnect vacuum hose from vacuum pipe leading to vacuum tee connector. Raise car and remove engine side apron from left side. Remove electrical cables from behind cable guide on reservoir cover of brake unit. Remove coiled hydraulic pipe from outlet fitting on hydraulic cylinder and from tee connector. Disconnect pushrod from pedal and wires from stoplight switch. Remove nuts from U-bolt retaining pedal pivot bracket to steering column; remove pedal and pivot bracket (with stoplight switch assembly attached). Remove accelerator pedal. Push rubber grommet up on steering column and move floor mat out of way. On Synchro-mesh cars, remove clutch pedal seal retainer and steering column seal retainer and remove seals. On Hydra-Matic equipped cars, remove screws retaining mounting plate to floor pan and remove mounting plate with power brake unit attached. On Synchro-mesh cars, remove screws retaining power brake unit to mounting plate (brake will rest on frame). Remove screws retaining mounting plate to floor pan and remove mounting plate, "jockeying" as necessary to clear clutch pedal. Remove power brake unit. *(CAUTION—Do not support or carry brake unit by pushrod since pushrod may be pulled out of plunger).* Remove mounting plate from brake unit, if not previously removed, and remove vacuum hose from vacuum cylinder inlet tube.

DISASSEMBLY: *CAUTION—Use extreme care to prevent hydraulic system parts coming in contact with mineral oil or grease.* Clean all dirt from outside of unit, using care not to allow dirt or solvent to enter unit. Remove fluid filler cap or dipstick and gasket then empty fluid out of reservoir. On Lincoln, remove screw that secures heat shield to booster body, remove shield by sliding it off hydraulic cylinder.

►*CAUTION: Before further disassembly, scratch alignment marks at the following points: (1) Vacuum cylinder shell and vacuum cylinder end plate. (2) Vacuum cylinder shell and hydraulic cylinder casting. (3) Reser-*

CONTINUED ON NEXT PAGE

BENDIX POWER UNIT (C nt.)

voir cover and hydraulic cylinder casting. (4) Tube fitting and hydraulic cylinder casting.

ALL MODELS

Hydraulic Unit: Place hydraulic unit in vise (lead jaws) at its normal mounting angle and remove the six cover screws, cover and gasket. Using a 1 1/8" (thin-wall) socket wrench, unscrew and remove compensator port and valve assembly. Remove rubber seal ring from port fitting. Unscrew hydraulic output fitting and remove fitting and take off rubber seal ring. Remove check valve assembly and valve spring. Separate check valve rubber cup and cup retainer. Remove unit from vise and empty remaining fluid. *NOTE*–Master cylinder piston assembly will be removed after vacuum cylinder is removed from hydraulic cylinder casting.

1953-54 MODELS

Vacuum Unit: Replace unit in vise. Release lip of valve rod boot from cylinder end plate and slip boot off over end of rod. Remove screws holding cylinder end plate and gasket and remove these parts. With a small-nose pliers compress ends of valve stop washer snap ring and pry out opposite side of snap ring. Remove snap ring, valve rod and valve assembly. Remove the screen from around vacuum valve. *(CAUTION*–Protect polished surface of vacuum valve assembly). Remove hose from vacuum inlet tube. Compress the vacuum piston into cylinder about ½" and remove inlet tube assembly and gasket. Lift out the piston assembly. Using care not to compress the master cylinder piston from its released position, compress the piston return spring about ½" and remove the return spring seat retainer, spring seat and return spring. Remove the three vacuum cylinder, mounting bolts and lockwashers. Remove vacuum cylinder, gasket, rubber seal ring and metal encased leather seal from hydraulic cylinder casting. Using special pliers, next remove master cylinder piston cup washer retainer ring and lift the master cylinder piston and seal parts as a unit from the hydraulic cylinder. *(CAUTION*–Protect polished surfaces of master cylinder piston). Remove the steel backup washer, phenolic guide washer, cylinder piston seal and seal retainer from the master cylinder piston.

Vacuum Piston: Scratch alignment marks on front and rear piston plates. Remove the piston steel and rubber stop washers. Remove the five packing plate screws, retainer plate, wick expander spring, wicking, vacuum piston seal retainer and seal. Turn unit over and remove the five piston plate screws and separate the front and rear piston plates, diaphragm assembly, counter reaction-spring, gasket and vacuum valve return spring.

1955 MODELS

Vacuum Unit: 1) Replace unit in vise. Release lip of valve rod boot from cylinder end plate and slip boot and felt off over end of rod. Bend up two tabs on end plate and separate end plate and end plate gasket from cylinder. Slide vacuum hose off vacuum tube attached to vacuum cylinder. Remove air cleaner screw and separate screw gasket, shell, hair and rubber seals from vacuum cylinder. Remove two vacuum tube attaching screws, vacuum tube and gasket. *(CAUTION*–Inspect inner surface of vacuum cylinder under holes for burring from attaching screws. Remove burrs to prevent damage to power piston assembly). Pull out piston assembly from vacuum cylinder.

2) Compress piston return spring about ½" and remove the return spring seat retainer, spring seat and return spring. Remove the three vacuum cylinder mounting bolts and lockwashers. Remove vacuum cylinder, gasket rubber seal ring and metal encased leather seal from hydraulic cylinder casting. Using special pliers, next remove master cylinder piston cup washer retainer ring and lift the master cylinder piston and seal parts as a unit from the hydraulic cylinder. *(CAUTION*–Protect polished surfaces of master cylinder piston). Remove the steel backup washer, phenolic guide washer, cylinder piston seal and seal retainer from the master cylinder piston.

Vacuum Piston Stop, Compensating Stem & Vacuum Hose: Remove vacuum hose from piston tube. Remove tube screw and separate tube and rubber seal from piston assembly. Visually inspect condition of rubber stop. If there is no evidence of wear or damage, remove screws and remove steel stop washer with rubber stop attached. If rubber stop warrants replacing, separate stop from steel washer before removing steel washer. Remove compensating stem diaphragm and compensating stem.

Vacuum Piston, Valve Pushrod & Plunger: Hold rear piston plate assembly in vise using care not to damage surface at vacuum tube port. Loosen five piston plate screws and separate front piston plate, gasket, diaphragm assembly and counter-reaction spring from rear piston plate assembly. Remove vacuum poppet spring screw, spring from rear piston plate. Using pliers, remove atmosphere poppet retaining clip. Break clip, if necessary, to remove from poppet stem. Separate atmosphere poppet spring and atmosphere poppet from piston plate. Remove pushrod and plunger, and vacuum poppet assembly from piston plate. From groove in bore of piston plate, remove plunger stop ring. Using sharp tool under end of Spirolox ring, remove ring from groove at end of plunger. Separate pivot washer and pivot arm from plunger. Remove clip and separate vacuum poppet from pivot arm. From recess around plunger remove flat rubber seal.

Rear Piston Plate Packing & Plates–Place rear piston plate on bench, with packing and plates facing upward. Remove six retainer plate attaching screws, retainer plate, ring wicking, piston packing plate and leather piston packing.

CLEANING & INSPECTION: Thoroughly wash all parts in diacetone alcohol. Use air hose to blow dirt and cleaning fluid out of recesses and internal passages. Remove rust or corrosion from bore of vacuum cylinder shell with fine emery cloth. Place all cleaned parts on clean paper or cloth to prevent possibility of dirt being assembled into power brake. Inspect all parts for wear or damage and replace as necessary. Particular attention should be given to following items:

Vacuum Cylinder Shell: Inspect shell for scores, pits, dents or nicks, or damaged threads in nuts or in mounting flanges.

Hydraulic Cylind r Casting: Examine bore down one inch from open end. For the hydraulic cup to seal properly, this portion of bore must be free from scores, deep scratches or corrosion. The sealing surfaces at the reservoir cover, compensating port, and hydraulic outlet port must be free of scoring, pitting, dents and nicked edges. Also check casting for cracks and damaged threads.

Hydraulic Port Fitting: The surface at the small end of the fitting must be free from scoring or corrosion which might prevent sealing with rubber cup of residual check valve.

Compensating Port Fitting: Inspect surface around port opening, inside threaded end of fitting, for scoring or corrosion which might prevent proper seating of compensating valve.

Valve Supply Tube: Make sure tube braze is secure and that tube plate is not distorted.

Piston Plates: Examine plates for cracks and damaged threads. Inspect plunger bore in rear piston plate and poppet seats for scratches and nicks. **Do not** attempt to refinish bore. Replace with new plate, if necessary.

Hydraulic Plunger & Washer Assembly: Inspect polished surface for scores, pits, or dents. **Do not** attempt to refinish plunger surface. Replace with new assembly, if necessary.

Pushrod & Plunger Assembly: Rod must pivot freely in plunger without any noticeable end play. Inspect plunger for scores, pits, or dents on outside diameter of polished surfaces. **Do not** attempt to refinish plunger surface. Replace with new assembly, if necessary.

Vacuum Cylinder End Plate: Examine for distortion.

REASSEMBLY: Before reassembly, make sure working area, parts, and tools are free of dirt, grease and oil.

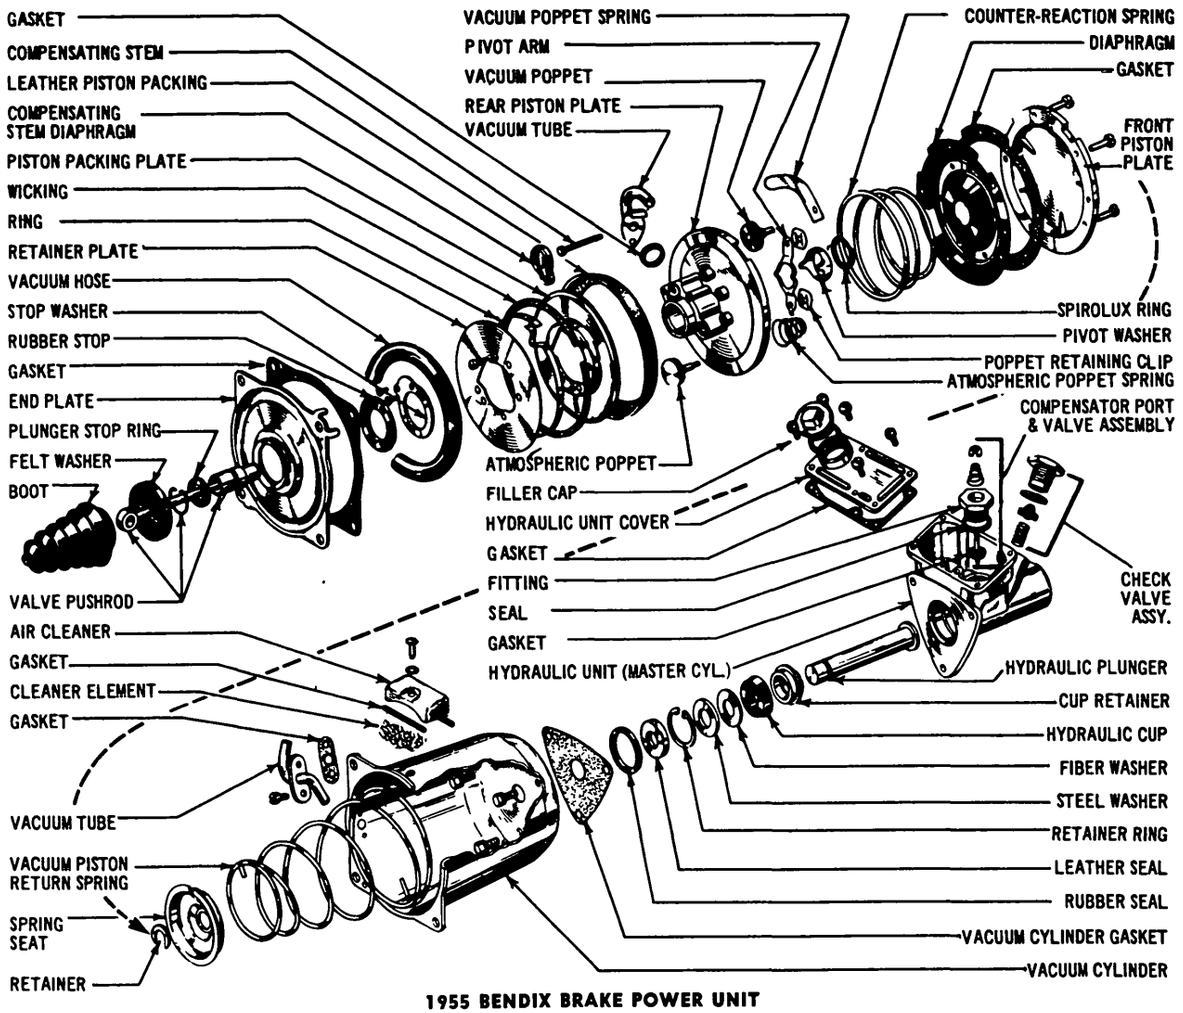
1953-54 MODELS

Master Cylinder Piston: Dip piston and cup in hydraulic brake fluid. Install cup retainer on piston with small end of retainer toward washer on end of piston. Dip cup in brake fluid, then install lip side of cup on cup retainer. Place piston-retainer-cup sub-assembly in hydraulic cylinder. Take care not to damage lip of cup as it enters cylinder bore. Install the phenolic guide washer and piston cup steel stop washer in place and install the retaining ring. Hold master cylinder piston in its outward position and install leather seal (with lip toward hydraulic cylinder).

Vacuum Piston: Place rear piston plate on bench with rear side facing up. Install Vacuum Piston Packing Assembly Ring over the piston plate, then install leather piston packing seal, lip side up, until it seats in recess of piston plate. Install vacuum piston packing seal retainer, wicking, wick retaining expander spring, wick retaining plate, and install the five retaining screws *(CAUTION–Care must be taken when installing these screws to apply sufficient downward pressur on screwdriver to partially compress the packing s al and thoroughly engage screw threads to prevent stripping the threads).* Turn vacuum piston over and install Diaphragm Installation Guide Pins into screw holes, then place the counter-reaction spring, small end down, on piston plate, and install reaction diaphragm (with large diaphragm plate toward rear piston plate) and gasket, over pins. Align the two air passage cutouts. Install the valve return spring with small end into reaction diaphragm (this will be over the back of

CONTINUED ON NEXT PAGE

BENDIX POWER UNIT (C nt.)



rubber pad). Install front piston plate, aligning the air passage cutouts or alignment marks. Press down front plate, compressing the spring, and remove one guide pin at a time, replacing each with a screw. Tighten screws uniformly. Saturate new wicking and wipe leather seal with a maximum of two teaspoons full of **shock absorber oil**. Fasten the vacuum tube and hose assembly and gasket to rear piston plate with two screws.

Vacuum Cylinder: Install master cylinder rubber seal ring and the cylinder gasket. Match aligning marks on vacuum cylinder and on hydraulic cylinder casting and install mounting bolts and lockwashers. Tighten to 4-5 ft. lbs. torque. Install the piston return spring engaging the hooked end of the large end of the spring between a mounting bolt and a small hump in the cylinder (any of the three). Place the spring retainer over the piston engaging hooked end of small end of spring in slot of retainer. Install retainer washer. Apply a thin coating of shock absorber oil to inside walls of vacuum cylinder and insert vacuum piston assembly into cylinder and align open end of hose with the center of the large elongated hole in vacuum cylinder. Push piston assembly into cylinder making sure that bore in vacuum piston front plate fits over master cylinder piston. Rotate piston assembly clockwise 20° to 30" and then 20° to 30° counter-clockwise. Move the piston through its full stroke a number of times to make certain open end of vacuum hose will be centered under elongated hole in vacuum cylinder after piston finds its normal working position. Install tube assembly, gasket and screw on vacuum cylinder. Tighten screw firmly and slip the hose on its connection. Again push piston into cylinder to its full stroke a number of times permitting it to return by itself and note if return spring causes piston to rotate. If it rotates enough to cause the coiled hose to rub against the inlet connection, remove piston and move piston return spring 120°.

Hydraulic Cylinder: Dip compensator rubber seal ring in brake fluid and install on compensator port fitting. While holding piston assembly forward in cylinder about ½", install port fitting and valve assembly and tighten securely. Dip line check valve rubber cup in brake fluid and assemble on cup retainer. Position spring and cup-retainer assembly on hydraulic output fitting lower face at small end of fitting. Invert the power unit and screw fitting into place, using care to see that parts remain in correct alignment. Tighten to 30-42 ft. lbs. torque. Assemble copper gasket, hydraulic tube fitting and the second copper gasket over fitting bolt. Screw assembly into outlet, aligning the marks previously made.

1955 MODELS

Compensating Valve: Insert stem of valve poppet assembly through hole in threaded end of fitting. Assemble large coil of poppet spring to fitting over end of poppet. Hold poppet on seat, compress spring, and insert "C" washer retainer in groove at end of stem. Crimp ends of "C" washer together to retain in place. Coat rubber seal with brake fluid and assemble over threads of fitting.

1955 BENDIX BRAKE POWER UNIT

Master Cylinder: 1) Coat residual check valve rubber seal with brake fluid and place over threads of hydraulic outlet fitting in inverted position, and insert cone end of cup and retainer assembly in end of fitting. Center check valve spring in recess of rubber cup. Hold master cylinder casting upside down and thread outlet fitting into hydraulic cylinder. Tighten to 50 ft. lbs.

2) Insert washer end of plunger into cylinder. Place cup retainer on plunger so that smaller inside diameter of retainer is toward plunger washer. Coat hydraulic cup with brake fluid and place over plunger; lip on cup must be toward cup retainer. Place Spauldite guide washer against cup. Place steel washer against guide washer. Slide all parts into bore of cylinder. *CAUTION*–Use care so as not to cut cup when placing on plunger and when inserting cup into bore of cylinder. It will be necessary to use a small screwdriver or similar tool having a smooth edge to start lip into bore.

3) Press parts into cylinder bore and insert snap ring using snap ring pliers. Be sure snap ring is engaged in recess. Push in on hydraulic plunger and then install compensating valve assembly into master cylinder. Pull back on plunger **to be sur** plunger washer tilts compensator valve. Tighten fitting to 15 ft. lbs. Place cover gasket on reservoir of cylinder. Align cover scribe marks and replace cover screws, with exception of rearmost screw on right hand side. Re-place filler cap or dipstick gasket, screw filler cap into cover or replace dipstick.

R ar Pist n Plate Packing & Plat s: Place piston assembly flat on work bench inside of piston assembly ring. Place leather packing against piston with lip up.

CONTINUED ON NEXT PAGE

BENDIX POWER UNIT (C nt.)

Place packing plate inside leather packing, with beveled edge of plate down against packing, so that "cutouts" and holes in plate are aligned with piston Coil wicking inside lip of leather packing Cut wicking to required size Remove wicking and dip in vacuum cylinder oil, let excess drip off and reinstall wicking Coil expander ring inside wicking with barbs pointing upward into wicking Engage notch at loop end of ring with hook at opposite end Replace and align wicking retainer plate Replace screws and tighten evenly

Vacuum Piston, Valv Pushrod & Plunger 1) Place stem of vacuum poppet in hole at rounded end of pivot arm and install two retaining clips making sure that clips are pushed down against pivot arm A piece of bar stock with 1/8 hole in end, or piece of brake pipe with flared end, facilitates installation Place rubber seal in recess of pushrod plunger with lip of seal toward pushrod Coat plunger with Lubriplate, place into bore of rear piston plate and engage snap ring in recess in bore of piston plate Place pivot arm vacuum poppet sub-assembly over end of plunger, insert pivot washer and engage Spiroluv ring into groove at end of plunger (Engage end of ring in groove and then screw into place) Place vacuum poppet spring into recess of piston plate and with end of spring over end of vacuum poppet stem, insert screw Place atmospheric poppet spring between pivot arm and piston plate with large coil of spring towards atmospheric port From opposite side of piston plate, place atmospheric poppet so that stem passes through plate, spring, and hole in pivot arm Install retainer clips on stem of poppet in same manner as before A length of round rod with a flat end can be used to back up atmosphere poppet when installing clips

2) Clamp rear piston plate assembly in vise and screw guide pins into place Place large end of counter-reaction spring in piston plate Place diaphragm over guide pins so that by-pass holes and notches in diaphragm and plate are aligned *NOTE*–When by-pass holes and notches are aligned, correct side of diaphragm will be toward piston plate

3) Move diaphragm downward until it seats on spring When properly seated, flange of metal ring will be within counter-reaction spring Place gasket and front piston plate over guide pins, making sure by-pass holes and notches are properly aligned

4) Apply force on front piston plate to compress counter-reaction spring until front piston plate rests on rear piston plate Loosely install two screws Remove guide pins, one at a time, and install remaining three screws, Tighten all screws evenly

Vacuum Piston Stop, Compensating Stem & Vacuum H se· Place vacuum poppet compensating stem into hole in recess in hub of piston plate Place compensating stem diaphragm in recess with "by-pass" slot of diaphragm outward and tab to left (when slot is toward you) Place steel stop washer over pushrod, align washer with hub of piston, replace two screws and tighten securely Soften coating of rubber stop (if stop was removed) with gasoline and cement to steel washer Position rubber seal in recess of piston, hook plate of tube to piston plate and replace screw, tighten screw securely Attach vacuum hose to tube and coil hose around hub of piston

Vacuum Cylinder: 1) Pull out hydraulic plunger, place Plunger Seal Installer (J-5405) over end of plunger, and assemble leather seal over seal tool with lip of seal toward master cylinder. Press seal into recess of master cylinder and then remove tool from plunger. Place rubber seal into master cylinder recess around leather seal. Align vacuum cylinder to master cylinder, and with gasket in place, insert three capscrews (and lockwashers), tighten to 6 ft. lbs

2) Place larger end of vacuum piston return spring in vacuum cylinder making certain hook on spring is between a screw head and a raised projection on end of cylinder. Assemble retainer plate over end of spring, aligning notch with hook on spring Compress spring, and with retainer plate over end of plunger, insert "C" washer into groove of plunger.

3) Apply thin film of vacuum cylinder oil to bore of vacuum cylinder and to lip of leather packing, insert piston into cylinder so that free end of vacuum hose is in line with center of hole. Push piston into cylinder, adjusting position slightly until hook seats between two web sections of front piston plate. Move piston 20-25° in both directions in cylinder and stroke piston against spring several times by hand, to allow piston to find its normal operating position. Check location of end of hose with respect to center of hole in cylinder Install tube and gasket and replace two screws. Slide end of hose onto vacuum tube approximately 5/8'. Operate piston by hand through its full stroke several times to make certain that hose does not rub against cylinder or piston. Should interference occur, remove and rotate piston to a new web position where interference does not occur.

Air Cleaner & End Plate: Place two rubber seals on bottom edges of air cleaner shell. Place hair in shell. Replace screw and gasket and attach air cleaner shell to vacuum cylinder. Be sure hair is under shell, a small steel scale or similar tool can be used to push hair under ends of shell. Align end plate gasket and end plate and place against vacuum cylinder. Bend over two tabs of end plate to secure plate to cylinder. Install rod guard felt in large end of boot. Dip small end of boot in brake fluid and place boot and felt over pushrod. Attach lip of boot to scallops at center of end plate.

INSTALLATION: To install power brake assembly reverse removal procedure and note the following

1953-54 MODELS

Vacuum Valve & Piston: *CAUTION–Check to see that movement of the vacuum piston is within 3/32" to 7/32" from its full released position. This movem nt should allow compensator valve to close. If this dimension does not check, unit is not assembled prop rly and should be rechecked.* If dimension checks install vacuum valve screen over the grooved port in vacuum valve and carefully insert the valve and rod assembly into vacuum piston (phenolic guide washer must be in place on rod) and install retainer snap ring. Install felt washer and rubber boot. Match fluid reservoir cover alignment marks and install cover and gasket, and filler cap and gasket.

1955 MODELS

Hudson & Nash: To prevent any contact during operation, a minimum of ¾" clearance must be maintained between centerline of pushrod-to-bell crank clevis pin and outer surface of front adjusting link locknut

Pontiac: There should be approximately 1/8' clearance between pushrod and bore of plunger at top or 12 o'clock position with brake pedal released. If improper clearance noted, loosen brake pedal pivot bracket and shift slightly to obtain clearance. *NOTE*– If clearance cannot be obtained, check for bent pushrod or bent mounting plate.

BUICK POWER UNIT

Buick (1953-54)

►CHANGES & CORRECTIONS

►*AIR-VACUUM CYLINDER PRODUCTION CHANGE Two types used, Series No. 2, identified by letter "K" in front of production date on head of unit, has no control or dampener springs on ends of reaction rod and stop and uses new type power piston and push rod. When overhauling Series No. 1 Power Brake Unit control and dampener springs must be discarded and new power piston and push rod installed. When changes made stamp or paint (use red or yellow) letter "K" on head of unit preceding date of manufacture.*

►*1953 POWER BRAKE VACUUM PUMP PRODUCTION CHANGE (To Provide Vacuum Reserve at Idle Speed)* —Effective October 1 1953 Vacuum Pump is part of power brake installation This unit may be installed on earlier cars *For data see "Description" below*

DESCRIPTION: Vacuum suspended type Self contained hydraulic vacuum power braking device utilizing engine intake manifold vacuum and atmospheric pressure for its power It consists of three separate units as follows

Power Unit: Three elements are combined to make up this single unit, namely
(1) **Air-Vacuum Cylinder** comprising a cylinder, power piston and piston return spring
(2) **Hydraulic Cylinder** containing an hydraulic plunger return spring, and compensating port
(3) **Control Valve,** mechanically actuated which controls degree of brake application or release in accordance with foot pressure applied to brake pedal It consists of a valve push rod, slide valve reaction rod, reaction spring assembly, and counter-acting spring

Hydraulic Fluid Reservoir· Mounted under hood

Manifold Check Valve: Located in vacuum source line Maintains vacuum in unit should engine stall

Power Brake Vacuum Pump: *NOTE—This unit part of Power Brake installation on all 1954 cars (and 1953 cars beginning Oct. 1, 1953).* Consists of a motor driven vacuum pump with a control relay (see Wiring Diagram) Control relay circuit is connected to

CONTINUED ON NEXT PAGE

BUICK POWER UNIT (C nt.)

accessory terminal of ignition switch (at the car fuse block) and is grounded through the generator main brush. The vacuum pump will operate whenever the engine speed is less than 250 RPM. with the ignition turned on, and supplies vacuum for the power brake operation. When the engine speed exceeds 250 RPM. (which is less than normal idle speed of 450 RPM.) the voltage developed by the generator causes the relay to open and cuts out the vacuum pump. At higher speeds manifold vacuum is sufficient to provide for brake power unit operation. The vacuum pump provides a "Stand-by" vacuum source in the event of engine stalling.

OPERATION: With engine running, brakes unapplied, full vacuum chamber of the unit (both sides of power piston) is held at engine manifold vacuum. Application of the brake pedal causes atmospheric port to open, admitting air to the cover side of the power piston, while full manifold vacuum is maintained on the cylinder side of piston. This pressure differential causes power piston to move forward, thereby exerting a thrust on the small piston in the hydraulic cylinder. This increases line pressure to the four wheels. Release of the brake pedal restores the vacuum balance in the power cylinder. Should failure in the vacuum power system occur, brakes can still be applied conventionally.

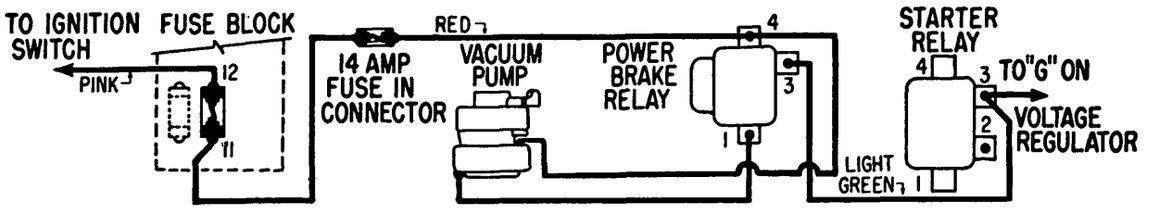
POWER BRAKE VACUUM PUMP: Used on all cars after Oct. 1, 1953. May be installed on earlier cars.

Servicing—No attention required other than pump lubrication. At 5000 mile intervals, remove filler screw from top of pump unit, fill as necessary with regular SAE 5 oil.

Specifications—Vacuum pump and motor assembly is Trico or Movac. Serviced as an assembly.

Control Relay—Delco-Remy No. 1116896. Contact gap should be .025" (.017-.033").

Contact Opening Voltage—5.7-7.2 volts.



Contact Closing Voltage—Not more than 3 volts after excitation of 12-15 volts.

Fuse—14 ampere. In fuse holder in line between the car fuse block and the control relay.

CHECKING & ADJUSTMENT: Check all parts of the power brake system before disassembling the Power Brake Unit whenever trouble is experienced.

Pedal Linkage Adjustment: In cases where hard or sticky initial pedal pressure is encountered or where pedal fails to return to release position when foot removed, check for lack of lubrication of pedal shaft or binding of clevis pin due to rusting or chloride corrosion. To correct latter condition drive out pin and install new pin or clean up old pin. (Early production has no grease fitting at this point —late production has straight fitting). If no fitting in lever, remove engine splash pan, drill and tap lower end of lever with 1/4 x 28 thread and install a 90° grease fitting. Grease fitting should be turned toward rear of car to permit access to fitting with grease gun. Reinstall splash pin. If binding still occurs with joints lubricated, it may be caused by mis-alignment of pedal shaft with push rod. With push rod in position loosen bolts which attach pedal shaft bracket to frame and permit bracket to shift to a free position. Retighten bolts.

Pedal Stop Adjustment: With pushrod removed, adjust pedal stop bolt so that pedal grommet is compressed to ½" height (1953), ⅞" height (1954). Tighten locknut.

BUICK POWER BRAKE VACUUM PUMP WIRING DIAGRAM

Push Rod Adjustment: After adjusting pedal stop, install push rod and loosen adjusting jam nut. Holding pedal against stop, adjust push rod length to provide 1/16" clearance or lost motion in power cylinder. Note that in making adjustment only finger tip pressure should be used in pushing rod into power cylinder. Pressures above two pounds will start valve moving. The 1/16" clearance should be in addition to any movement of cylinder valve. ***CAUTION—Great care must be taken when installing push rod into valve body. Any pressure on push rod will open valve. An open valve will build up pressure in hydraulic system causing brakes to lock after a few miles of operation.*** Shorter adjustment safer as long as push rod will actuate brake valve even with brake pedal fully released.

Brake Shoe Adjustment & Pedal Height: Brake shoe settings and procedures same as for manual brakes. After brake shoes properly adjusted, pedal will have certain height which cannot be adjusted up or down. Normal pedal height from lower, back edge of pedal to floor mat is approximately 2".

BLEEDING HYDRAULIC SYSTEM: Using pressure bleeder attached to fluid reservoir under hood of car, bleed **first** the cylinder **end** bleeder until fluid runs clear, **second** at cylinder **flange** bleeder, and last at the four wheel bleeders. When fluid runs clear at all points, start car engine, pump brake pedal several times, and rebleed at two bleeder screws on unit. After bleeding completed, check for brake system leaks while applying heavy brake pressure, with car engine running.

TROUBLE SHOOTING: If operation unsatisfactory, check as follows:

Brake System Loses Fluid: Tighten all connections. If fluid loss still occurs, the trouble is probably worn or damaged primary cup, seal, reaction cup, or reaction "0" ring. If evidence of presence of abrasive material, polish out light scores with very fine polishing paper, then thoroughly wash parts before assembly. Use Kit in reassembly. NOTE—If heavy abrasive action has taken place due to severe contamination of brake fluid, install new power piston and sleeve assembly after thoroughly flushing reservoir and wheel cylinder lines.

Brakes do not Release Properly: Brake pedal arm, fulcrum or pushrod clevis may be binding; push rod adjustment too long; inspection screw and gasket loose or missing; excessive friction caused by "dry" leather piston cup in 6" diameter air-vacuum cylinder. To remedy the latter lubricate cup by oiling through inspection hole in head of unit, using only 2 or 3 ozs of special oil furnished in Kit. Then back off shoes and, with engine running, pump pedal several times until leather frees up. CAUTION—***Do not pour this special oil into reservoir. It will contaminate fluid.*** Other causes of above difficulty are plugged compensation holes near end of power piston sleeve, broken residual valve spring or power piston return spring, cylinder mis-alignment, damaged or weakened control spring or dampener spring in Series 1 units, or weak or damaged reaction rod spring in Series 2 units (Series 1 units have date only on head of unit, Series 2 units have date preceded by "K"—See Production Change above); excessively dry "0" ring on outside diameter of air valve seat (Series 2 units only). Use entire Kit when making replacements.

Power Unit does not Boost: To determine if unit operating, stop engine, then depress brake pedal several times to eliminate all vacuum from system. Apply brakes, and while holding foot pressure on pedal, start engine. If unit operating, pedal will move forward when vacuum power is added to pedal pressure. **If above check shows unit not operating** manifold check valve may be stuck in closed position; bent, broken, or obstructed vacuum source line from engine to check valve or check valve to unit; blocked air inlet to air cleaner cover; blocked air passage in guide sleeve under boot; jammed air valve seat in power piston due to foreign material becoming lodged in power piston air valve seat bore cavity. **If above test shows unit is operating** difficulty may be damaged secondary cup, insufficient fluid in system, glazed brake lining, grease or brake fluid on linings, bound up pedal fulcrum or push rod clevis. When replacing parts, use **entire kit.**

REMOVAL: Remove cranking motor splash pan. Disconnect return spring, remove clevis pin at front end, then remove brake pedal pushrod with cylinder pushrod attached. Disconnect breather tube which is clamped to inlet tube on power cylinder air cleaner cover. Disconnect hose and pipe from vacuum chamber (rear) end of power cylinder. Disconnect reservoir-to-hydraulic cylinder pipe, allow reservoir and pipe to drain. Disconnect distributor-to-cylinder pipe and allow to drain. **Discard old fluid** and cover pipe ends with tape to exclude dirt. Remove nuts and lockwashers attaching power cylinder to its support and remove cylinder from car.

INSTALLATION: To install, reverse removal procedure, except for installation of pushrod and splash pan. Adjust brake pedal stop and pushrod, then bleed hydraulic system.

DISASSEMBLY: Major Components.

Thoroughly clean entire exterior of Brake Power Unit, being careful not to allow dirt and solvent to enter unit. ***CAUTION—Use extreme care to prevent hydraulic system parts coming in contact with mineral oil or grease.***

1) Remove push rod boot and discard.
2) Clamp unit in vise with hydraulic cylinder end

CONTINUED ON NEXT PAGE

BUICK POWER UNIT (Cont.)

down. In clamping unit USE NO MORE PRESSURE THAN NECESSARY TO HOLD IN POSITION (to avoid cracking or distorting cylinder).

3) Remove air cleaner cover, lift out cleaner core.

4) Remove three head bolts and lockwashers, then insert screwdriver in slots in flange, twist, then remove head by tapping up evenly on flange, using screwdriver and heel of hand, or light hammer. CAUTION—Removing head releases return spring unless power piston held down during head removal. Remove return spring.

Vacuum Side of Unit: 1) If power piston and guide have been removed with head, set power piston assembly (with head) in holding fixture with power piston end down and guide end up, lift head off power piston guide. Remove "0" ring and bumper from outside diameter of head, discard.

2) Place head in arbor press with inside face up. Remove bearing, "0" ring, and guide seal. Discard "0" ring and guide seal, but not bearing.

3) With power piston assembly still in holding fixture, bend back lip of leather piston cup, remove wick and expander spring, discarding wick only.

4) Disassemble power piston and guide assembly by removing three bolts and lock washers, lift guide assembly off power piston. Discard "O" ring.

5) Remove floating control valve assembly from guide assembly, discard valve but not spring. Lift off leather piston cup and discard, lift air valve seat out of power piston and discard.

6) Lift out control spring (Series 1 only) and reaction rod spring from power piston, lift out reaction rod and stop assembly, lift out dampener spring (Series 1 only). *Discard Series 1 control and dampener springs* (See Production Change above). Remove washer from reaction rod and stop assembly, discard washer.

7) Insert drift pin into center of power piston, push out reaction rod piston assembly. Using *extreme care* to avoid marring piston, remove "0" ring and reaction cup from reaction rod piston, discard.

Hydraulic Cylinder: 1) Drain hydraulic cylinder thoroughly *(do not re-use fluid)*.

2) Set housing and cylinder assembly on bench, with cylinder end up, remove four hex nuts and lockwashers from cylinder flange, lift cylinder off housing, discard cylinder-to-housing "O" ring.

3) Place cylinder in vise with outlet end down and flange end up; *do not grip tightly*. Using wrench, remove cylinder plug assembly (turn counterclockwise). Disassemble cylinder plug assembly *by hand* by removing primary cup, retainer and seal. Discard cup and seal but not retainer.

4) Remove power piston bearing assembly. Be careful to avoid marring inside diameter of bearing. Withdraw bearing carefully. *CAUTION—Removal of bearing releases residual valve spring, which will fly out unless controlled.*

5) Remove secondary cup retainers and secondary cup. Discard cup but not retainers, remove "0" ring and discard. Unless damaged, do not remove blue steel secondary cup supporting washer. If necessary to remove, apply compressed air to a filler port on outside diameter of bearing.

6) Lift residual valve spring retainer off hydraulic cylinder, then lift spring and residual check valve assembly out of cylinder. Remove residual check valve assembly from end of spring by prying off with screwdriver, discard valve. Remove and discard rubber residual check valve seat (loosen from end of cylinder by prying with a screwdriver).

CLEANING & INSPECTION: Before any part of unit is reassembled, all parts must be thoroughly cleaned, using diacetone alcohol or clean brake fluid. Avoid allowing any dirt or grit to get into unit during assembly.

REASSEMBLY: *NOTE—The Power Brake Cylinder Overhaul Kit includes all necessary replacement parts for both vacuum and hydraulic elements. Whenever unit disassembled for service, all parts contained in Kit should be replaced, regardless of whether they show wear at the time. BEFORE REASSEMBLY, WET ALL "O" RINGS AND CUPS WITH BRAKE FLUID, EXCEPT PRE-GREASED "O" RINGS AND SEALS SUPPLIED.*

1953 MODELS

▷*VACUUM POWER CYLINDER PRODUCTION CHANGE: Series 1 & Series 2 Brake Power Unit Reassembly procedures different. See Changes & Corrections.*

Hydraulic Cylinder: 1) Clamp hydraulic cylinder in vise, flange end up. Drop new residual check valve seat in place (be sure it is nested properly in end of cylinder), assemble new residual check valve assembly onto small end of residual check valve spring; valve assembly will snap on to end of spring with hand pressure.

2) Insert valve and spring assembly into cylinder with valve end first (be sure valve rests against seat), then place spring retainer on upper end of spring small end up.

3) Reassemble bearing assembly by installing new "O" ring in groove on outside diameter of bearing; install blue support washer (if removed), new secondary cup and cup retainers in bearing.

4) Reassemble cylinder plug assembly by inserting new seal, seal retainer (flat side out), and primary cup in plug.

5) With cylinder still held in vise, flange end up, reassemble bearing assembly and plug assembly into cylinder. Lubricate "O" ring on bearing assembly with brake fluid, insert bearing into cylinder with cup retainer end down. Install cylinder plug assembly in same operation, using drift pin to hold residual check valve spring down; plug can then be turned by hand. Use wrench to tighten securely, *do not force.*

6) With housing resting on bench, cylinder end up, install new cylinder-to-housing "O" ring, then assemble cylinder to housing so that bleeders on cylinder are on opposite side from the vacuum inlet on housing. Assemble cylinder flange nuts and lockwashers to studs, *but do not tighten.* Place housing and cylinder assembly back in vise, cylinder end down, housing end up.

1954 MODELS

Hydraulic Cylinder: 1) Mount hydraulic cylinder in vise with flanged end up. Install spring, residual check valve with concave side outward, and head nut with new gasket, and check valve seat in hydraulic cylinder. Tighten nut securely.

2) Install secondary cup retainer in cylinder with notched edge inward, then install secondary cup with flat side outward, using care that cup lip is not turned back at any point. Place secondary cup support washer on piston bearing with brake fluid, install bearing with notched face outward, and center of bearing in cylinder bore.

3) Place primary cup spacer on piston bearing with notched edge down and center it on bearing so it will not be damaged when cylinder plug is installed.

4) Install a new seal into cylinder plug with flat side inward, seal retainer with flat side outward, and a new primary cup with flat side inward against retainer. Use finger to force outside lip of both seal and cup down and outward against bore of plug to insure sealing contact. Screw plug into hydraulic cylinder by hand, then tighten it firmly with a wrench but do not use force.

5) Place new "O" ring around cylinder plug, then install hydraulic cylinder on housing with head nut on opposite side from vacuum tube on housing. Install nuts on all studs but do not tighten.

ALL MODELS

Power Piston Guide Assembly: NOTE—Before reassembling Guide Assembly, inspect inner end of guide sleeve where it seats against air valve seat assembly. *This must be Smooth and Clean.*

1) Assemble expander spring to power piston guide assembly, with ends bent in. With power piston guide on bench, shaft end up, by hand place spring in groove so that approximate center of spring coincides with one of the four slots in power piston guide flange; insert wedge (supplied in Kit) through slot to hold spring in place. Next, wrap each end of spring around power piston guide, secure with wedges in two side slots, then complete wrap of spring, with ends overlapping under fourth slot, lock in place with fourth wedge. Remove first three wedges *(CAUTION—Final wedge will be removed in step 5—wedges must be removed at final assembly).*

2) Saturate wick in special oil supplied with Kit, assemble to power piston guide over expander spring with grain of felt running parallel to centerline of power piston. Be sure joints of wick and spring do not coincide.

3) Invert assembly and set in holding fixture, assemble new leather cup to power piston guide, then slide service ring down over leather cup. Be sure heel of leather cup does not ride over edge of power piston guide and flange lies flat against its face.

4) After wetting inside diameter of new floating control valve assembly with brake fluid, place spring on retainer. Press complete assembly down on power piston guide stop. Install new "O" ring on hub.

1953 MODELS

Power Piston, Guide & Reaction Rod Assembly: *NOTE—In reassembling all Series No. 1 units use new Power Piston and Push Rod. See Production Change above.*

1) Assemble new reaction cup and "O" ring on reaction rod piston, with lip of cup toward small end of piston. *Do not disturb silicone grease on ring.*

2) With power piston and sleeve assembly on bench, sleeve end up, and after wetting cup with brake fluid, assemble reaction rod piston assembly into power piston sleeve with lip of cup facing up. Invert assembly and place in holding fixture.

3 Install new stop washer over reaction rod and stop assembly so that it rests snugly against stop, drop assembly into power piston. Install reaction rod spring into inside of reaction rod stop.

4) Insert new rubber push rod bumper into air valve seat, nesting it snugly at bottom of push rod cavity; install new "O" ring in groove on outside of air valve seat, using care to preserve silicone grease; then

CONTINUED ON NEXT PAGE

BUICK POWER UNIT (C nt.)

install this air valve seat assembly into power piston over reaction rod stop. ***CAUTION—Steel air valve seat will damage aluminum vacuum valve seat unless inserted with extreme care.*** Test action of air valve seat against spring for freedom of movement.

5) With power piston and sleeve assembly still resting in holding fixture, assemble power piston guide assembly to power piston and sleeve assembly as follows: Insert push rod through power piston guide and into push rod cavity in center of air valve seat; hold air valve seat down against reaction rod spring, position guide on power piston, start bolts with lockwashers installed. Use three of six holes in guide (other three holes are air passages). After starting one bolt and lockwasher, ***remove remaining expander spring wedge,*** install remaining two bolts and lockwashers, tighten all three bolts using care not to strip threads, remove service ring.

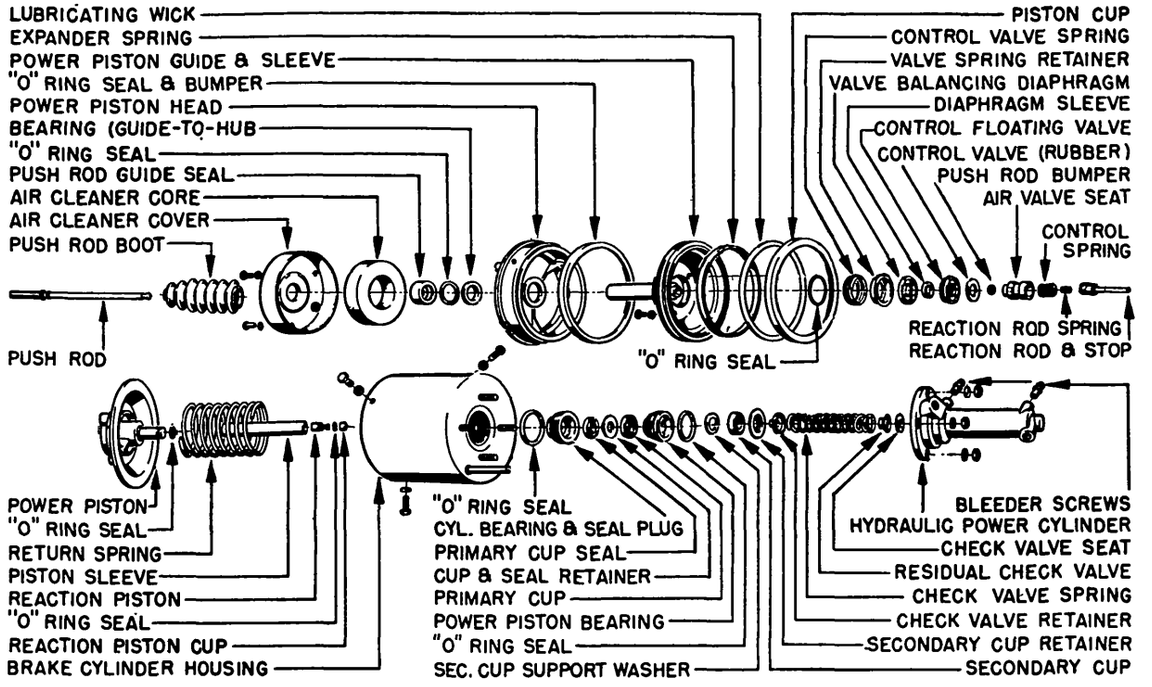
Head, Bearing & Seal Assembly: 1) With cylinder head resting on bench, hub end up, insert bearing with flat side down, then press new "O" ring into bearing groove with finger. Insert new greased guide seal (felt side up), use care not to remove grease. 2) Using arbor press, apply load to **outside edge** of seal, press into position. Apply only enough pressure to bottom seal on bearing, ***do not crush.***

1954 MODELS

Power Piston, Guide, Reaction Rod & Head Assembly: 1) Install a new metering hole seal over end of reaction rod in bore of stop and press down firmly. Install a new stop washer over other end of rod and seat it firmly against the stop.

2) Install new "O" ring in groove of reaction rod, being careful to preserve silicone grease on "O" ring, then install reaction rod in piston with a twisting motion.

3) Install a new "O" ring in groove of reaction piston, being careful to preserve silicone grease on "O" ring, then install piston over end of reaction rod **with wide land inward,** and press it down into bore of power piston sleeve.



4) Wet a new reaction cup with brake fluid, place it over end of reaction rod with lip side outward and carefully push it down into bore of power piston sleeve. Install spring and retainer over end of reaction rod, compress spring and install a new cotter pin to retain these parts.

5) Mount piston on holding fixture with sleeve down, then install control spring around reaction rod stop.

6) Install new "O" ring in outside groove of air valve seat, being careful to preserve silicone grease on "O" ring, then install valve seat assembly in power piston above reaction rod. ***CAUTION***—Use care to avoid damaging vacuum valve seat on the aluminum piston.

7) Place piston guide over piston and insert push-rod through guide to hold air valve seat down against reaction rod spring while starting bolts with lockwashers. Use three equally spaced holes in guide (Other three holes are air passages). After starting one bolt, remove expander spring wedge, then install other bolts and tighten all securely, using care not to strip threads in aluminum piston. Remove service ring.

8) Place cylinder head on bench, hub end up. Insert new guide seal into hub between bronze bearing and flat wick retainer washer that are inside hub; lips of seal must be upward away from bearing. Slide wick retainer washer down against seal, install a new wick in hub between washer and outer lip of hub, then move washer up snug against wick. Apply any remaining grease in seal and wick packing envelopes to inside of hub.

TYPICAL BUICK BRAKE POWER UNIT ASSEMBLY

ALL MODELS

Complete Unit: 1) Install new rubber "O" ring and bumper on outside diameter of head, then wet outside diameter of rubber with oil supplied in Kit. Oil inside of vacuum cylinder and oil leather cup on outer diameter of power piston guide.

2) With housing and cylinder assembly held in vise, housing up, install return spring so that it nests inside the four cylinder flange head bolts.

3) Set power piston and guide assembly in place with retaining shoulder nesting in return spring, then press power piston and guide assembly down against return spring and into housing about two inches. Pour remaining special oil supplied in Kit (should be 1-2 ozs.) into housing on power piston assembly. ***Avoid pouring oil into air holes.***

4) While holding power piston down, assemble cylinder head assembly over power piston guide sleeve and into housing. Locate head with inspection screw hole on opposite side from bleeders on hydraulic cylinder (1953), on opposite side of unit from vacuum tube on other end of housing (1954).

5) Remove assembly from vise and press guide sleeve end down on bench to hold piston and guide in fully applied position while tightening hydraulic cylinder stud nuts evenly. Power piston must move freely when all nuts are tight.

6) Blow out or replace air cleaner core, install core and cover, placing air inlet tube on same side as hydraulic cylinder bleeders (1953), on same side as inspection hole screw in cylinder head (1954).

7) Install new boot on pushrod and install rod and boot, placing end of boot securely over flange on air cleaner cover.

HYDROVAC POWER UNIT

Cadillac (1954-55)
Ch vr l t Trucks (1946-55)
F rd Trucks (1953-55) ①

►CHANGES & CORRECTIONS

►*1954 CADILLAC ACTUATING PISTON & CYLINDER ASSEMBLY PRODUCTION CHANGE:* **Starting with Engine Serial No. 54038 a new 3/8" Actuating Piston and Cylinder Assembly entered production replacing the earlier 5/16" piston and cylinder. Units with the later type piston and valve are identified by the number 377144 stamped on the brass identification tag. Units with the 5/16" assembly have number 376755 (production units), 376930 (replacement units) stamped on identification tag.**

►*1955 CADILLAC PRODUCTION CHANGES:* The following changes over previous models have been made in 1955 production: **(1)** ½" diameter control valve piston replaces smaller piston formerly used, thereby reducing pedal pressure required for brake assist. **(2)** Use of a smaller master cylinder boot and pedal shaft seal at toe-board have eliminated need for brake pedal retracting spring. **(3)** Residual check valve, formerly located in master cylinder, is now located in hydraulic cylinder end cap on power assembly.

►*1955 CHEVROLET PRODUCTION CHANGE:* Beginning with 2nd Series (Except Low Cab Forward) residual check valve has been incorporated in hydraulic cylinder end cap on power assembly.

►*1955 STUDEBAKER CONTROL VALVE PRODUCTION CHANGE (To Provide Softer Brake Fedal):* Beginning Serial Nos. G-1334649 (16G6), 8403935 (16G8), 7160012 (6HY), and 7160032 (6HC & K), a 7/16" control valve is used in place of 3/8" control valve formerly used. Kit, Part No. 537939, available to make installation on earlier cars. *CAUTION*—7/16" conversion kit is for use on 1955 Models **with factory installed** Power brake units only, it is not recommended for installation on any car with power brakes having the high (7 1 ratio) brake pedal.

DESCRIPTION: Bendix HYDROVAC Power Unit connected in hydraulic brake line between master cylinder and wheel cylinders (no mechanical connection).

OPERATION: As brake pedal is depressed, the hydraulic pressure developed in the master cylinder is transmitted to the power brake hydraulic cylinder and to the power brake hydraulic cylinder and to the hydraulic piston in the vacuum control valve. As the hydraulic piston in the power brake hydraulic cylinder is against the stop washer when pedal is first depressed, the check ball in the piston is held off its seat by the piston yoke. This allows fluid from the master cylinder to pass through the piston directly to wheel cylinders. This feature permits normal operation of brakes when engine is not running. Fluid under pressure is also directed to the hydraulic piston in the vacuum control valve. As fluid pressure moves this piston, it actuates the vacuum diaphragm control shaft and forces diaphragm against vacuum poppet valve sealing off atmospheric side of diaphragm from manifold vacuum. Continued movement of the piston and the diaphragm, forces the atmospheric poppet valve off its seat and admits air under atmospheric pressure to vacuum piston.

BLEEDING BRAKES (Except Cadillac): *(CAUTION—This operation must be done with engine stopped and no vacuum in the power brake system).* Attach bleeder hose to bleeder valve on control body, keep end of drain hose below surface of fluid in drain jar. Loosen bleeder valve ½-¾ turn. Depress brake pedal slowly by hand to expel air When pedal has reached toe board, close bleeder valve before returning pedal to released position Repeat this procedure until air bubbles cease to appear at the end of the bleeder drain hose in the jar and the stream is a solid fluid mass, then tighten bleeder valve and remove drain hose. *(NOTE*—**During the operation the brake master cylinder must be filled with fluid).** Following above procedure, bleed at bleeder valve on end cap of hydraulic cylinder, then proceed to bleed wheel cylinders in the usual manner.

BLEEDING BRAKES (Cadillac): Use same procedure as described above for cars other than Cadillac, except as follows: Bleed valve on end cap of hydraulic cylinder first, then valve on control valve body.

LUBRICATION: Remove screw plug on front end of vacuum cylinder and fill cylinder to level of hole (Studebaker 1 oz.) with Delco Shock Absorber Fluid or Bendix Hydraulic Cylinder Fluid as follows:
Cadillac: Once yearly.
Chevrolet: Every 10,000 miles.
Ford & Studebaker: Once yearly or every 20,000 miles.

TROUBLE SHOOTING: Before trying to determine cause of trouble, make certain that master cylinder reservoir is full, that brake system is free of air, that there are no binds in the brake linkage, that there are no air or fluid leaks to the master and wheel cylinders. Then proceed as follows:

Hissing Sound (Engine Running), Brakes Either On or Off: Caused by external leak on vacuum side of control diaphragm. Check and correct leak at control valve body, diaphragm, and gasket to end plate. Check and correct leak between vacuum cylinder and end plate.

Hissing Sound (Engine Running), Greater When Brakes Off: Caused by external leak on atmospheric side of control valve diaphragm. Check and correct leak at atmospheric poppet, external pipe and rubber tubing, and valve body screws.

Hissing Sound (Engine Running), Brakes On: Caused by internal vacuum leak, air entering through breather. Overhaul unit and check for leak at vacuum poppet, control diaphragm, or vacuum power piston.

Little or No Boost From Power Brake (May be Accompanied by a Hissing Sound or Loss of Brake Fluid):
1) Internal vacuum leak between atmospheric and vacuum side of power piston. Overhaul unit, and check for leak at vacuum poppet, control diaphragm, or vacuum power piston.
2) Internal hydraulic leak. Check for low brake fluid level. Overhaul unit and check for presence of brake fluid in inner side of vacuum cylinder, or inner side of control diaphragm. Check and correct leaks at control valve cup, control valve fitting "O" ring seal, vacuum piston push rod seals, or hydraulic power piston cup or ball check.
3) External hydraulic leak. Check and correct leak at point of origin.
4) Internal friction. Check and correct shock absorber fluid level in vacuum cylinder. If necessary, overhaul unit and check for rusty, dirty, or distorted vacuum cylinder wall, dry or worn vacuum piston leather packing, swollen rubber cups due to heat or wrong brake fluid, worn or damaged rubber cups, or dirt, rust, sludge, or foreign matter in power piston or control valve regions.

Booster Loses Effectiveness While Stopping (P dal Grows Harder or "Kicks Back"): Caused by internal hydraulic leak or internal or external vacuum leak. Overhaul unit and check for leaks at control valve, valve fitting, power piston, vacuum poppet, control diaphragm, or vacuum power piston. Check for sticking power piston, or restricted air cleaner (if so equipped).

Tendency To Over-Brake (Pedal drops under foot. May show up as slow operation of power brake): Restriction in atmospheric passage or sticky control valve. Clean air filter for restriction in atmospheric passage. If necessary, overhaul unit and check for misalignment of control valve assembly. Check for dirty or sticky vacuum or atmospheric poppet, as well as sticky control valve. NOTE—Above condition may also be caused by internal hydraulic leakage or internal friction. To correct, overhaul unit and check for leak at hydraulic power piston cup or ball check. Check for binding in power piston assembly. Check level of lubricant in vacuum cylinder.

Brakes Slow to Release (or fail to release complet ly): May be caused by sluggish control valve action or internal friction. Overhaul unit and check for weak vacuum power piston return spring or atmospheric poppet return spring. Check for dirty or sticky control valve. Check for power cylinder lubricant level. If necessary overhaul unit and check for binding in power piston assembly.

No Power Assist (on first application after engine shut off): Caused by an external vacuum leak or an internal vacuum leak in the check valve. Check and correct external leaks at valve body, external pipe, vacuum cylinder, and atmospheric poppet. For the internal leakage, overhaul or replace check valve assembly.

Brakes Apply When Engine Started: Caused by broken or improperly assembled atmospheric valve return spring or control valve diaphragm return spring, sticking control valve piston.

Air in Hydraulic System: Caused by an improperly assembled, defective or missing control valve piston secondary cup.

Grabbing Brakes: Caused by sticking control valve piston or sticking power piston.

Loss of Fluid from Brake System: Caused by defective hydraulic cylinder cup or seal, defective or damaged control valve piston cup (crack or split in lip at center of cup), dirt chips or other foreign matter under lip of piston cups, improperly tightened or defective gaskets or rubber seals.

HYDROVAC POWER UNIT (C ntinued)

P wer Unit Fails to Operate: Low or no vacuum due to clogged or restricted lines, defective check valve, clogged air filter (if so equipped).

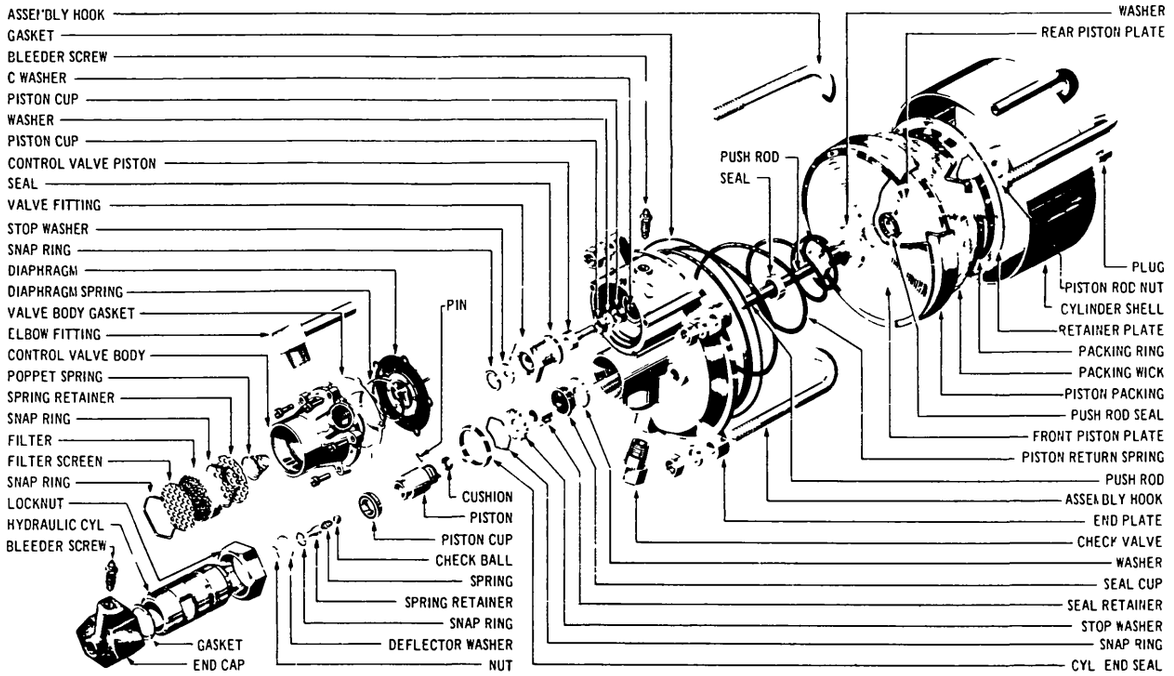
REMOVAL OF POWER BRAKE UNIT: Disconnect brake lines at cylinder end plate. Loosen vacuum line hose clamp at check valve and slide hose off. Remove three nuts and lockwashers from cylinder mounting bracket and remove unit from car. *NOTE*–Ford and Studebaker have stop light wires that must be disconnected before unit is removed.

DISASSEMBLY OF POWER BRAKE UNIT: When disassembling Power Brake use care in handling parts to prevent their coming in contact with mineral oil or greases. Do not handle hydraulic cups and seals with greasy hands.

Hydraulic Cylinder Assembly: 1) Loosen the cylinder nut and unscrew hydraulic cylinder assembly from end plate. Hold end cap in a vise and remove hydraulic cylinder from cap using an open end wrench on the flat part of cylinder. Remove gasket and bleeder fitting from end cap.

2) On 1954 Cadillac, Chevrolet 1955 1st Series and Earlier Trucks, and Studebaker, remove the bolt holding the hydraulic line end connection to the end cap and remove fitting and copper gaskets. Scribe line on cylinder shell and end plate so these parts can be reassembled in their original positions. Loosen hook bolts and remove cylinder shell, sliding tube out of rubber hose.

3) On 1955 Cadillac, 1955 Chevrolet 2nd Series Trucks, and Ford, remove residual check valve snap ring, spring seat, spring and residual check valve. Loosen hook bolts and remove cylinder shell, sliding connector pipe out of rubber hose.



4) On all cars, compress piston spring by pressing down on end plate. Hold piston in position with Vacuum Piston Retaining Strap, Tool J-5650 (two wire hooks and a plate can readily be made to hold piston in position). Remove hydraulic piston assembly from pushrod by holding retaining spring back and removing small pin. Remove hydraulic piston cup from piston, remove snap ring, retainer, spring, and ball. Remove hydraulic cylinder and seal. Remove snap ring, then remove pushrod seal cup parts. Drive out pushrod leather retainer with a flat end rod or drift.

Vacuum Control Valve Assembly: 1) Scribe control valve body and end plate to insure proper location on reassembly. Remove control valve body screws and remove control valve assembly with diaphragm and gasket. Remove diaphragm from control valve body.

2) On Cadillac and Studebaker, remove air intake filter snap ring, screen and filter, and take out lower snap ring and screen.

3) On Chevrolet and Ford, remove snap ring which retains cover on control valve and poppet assembly and remove cover, valve spring and gasket,

4) On all cars, remove hydraulic control valve fitting from end plate. Push piston out of fitting and remove cups from piston (washer between cups on Chevrolet and Studebaker). Remove seal, retainer ring, and stop

HYDROVAC BRAKE POWER UNIT

washer from fitting.

Vacuum Piston: Remove nut from threaded end of push rod, retainer plate, packing, and expander ring. Remove small diameter piston plate with rubber seal ring. Remove leather packing, larger diameter piston plate, and washer from push rod.

Vacuum Piston Pushrod Assembly (Ford): Remove pushrod lock ring from groove in piston guide. Remove spring washer, then lift out pushrod, spring, bottom spring washer, and bottom lock ring.

Vacuum Piston Pushrod Guide (Ford): Clamp hexagonal section of guide sleeve in a vise. Remove guide sleeve to body gasket, washer, and nut. Loosen outer locknut, then remove assembly from vise. Remove locknut, gasket, and guide sleeve. Remove piston guide by drawing it into cylinder shell.

Check Valve (Cadillac & Studebaker): Remove assy. from elbow in end plate. Remove plug from bushing and bushing from check valve assembly. Remove snap ring, spring retainer, and spring with check ball. Remove spring from check ball.

REASSEMBLY OF POWER BRAKE UNIT: Before reassembling unit, clean all parts thoroughly, and after cleaning, wash all parts for hydraulic system in alcohol. Be careful not to get grease or oil on hydraulic parts. Use new rubber seals and cups when reassembling.

Vacuum Pist n: (*NOTE*–An assembly ring can be made by cutting a 1" section from end of a power cylinder). Place front (larger) piston plate in assembly ring with lip down. Place new leather packing on plate with lip up, place new rubber seal in center of plate. Install rear (smaller) piston plate with lip down. Coil new wick inside lip of packing and cut it to proper size. Soak wick in cylinder oil (not ordinary oil) and allow it to drain thoroughly. Install wick. Place packing ring inside wick with gripper points up, and engage notch at loop end of ring with hook at opposite end. Install wick retainer plate with cutout portion over loop of expander ring. Place flat washer over threaded end of pushrod (guide rod on Ford), insert pushrod (guide rod) through assembled piston parts, being careful not to damage inner seal ring. Large piston plate should rest against flat washer. Clamp hex on pushrod (guide rod) in a vise, being careful not to damage polished surfaces. Install nut and tighten securely, being careful not to allow either piston plate to rotate while nut is being tightened. Remove assembly ring. Stake nut with center punch.

Pushrod Assembly (Ford)–Clamp hexagonal section of guide rod firmly in a vise. Assemble pushrod attaching parts over beveled end of pushrod in following order: Lock ring, one spring retainer, spring (large end first), second spring retainer, snap ring (smaller). Use care in assembling smaller diameter snap ring in groove at lower end of pushrod, to avoid distorting ring. Insert end of pushrod in recess at end of guide rod. To attach pushrod to guide rod, compress spring and assemble to lock ring in groove of guide rod. Be sure lock ring is firmly seated in groove of guide rod.

CONTINUED ON NEXT PAGE

HYDROVAC POWER UNIT (Continued)

Vacuum Control Valve Assembly: 1) Install stop washer and retainer ring in hydraulic control valve fitting. 2) On Chevrolet and Studebaker, dip piston cups in brake fluid and install on piston with washer between cups. Install C-washer. Lips of both cups must point away from end of piston with hole in it.

3) On Cadillac and Ford, install new rubber cups on piston with lip of cups toward small end of piston. 4) On all cars, install piston in fitting with hole in end of piston next to stop washer. Install a new rubber seal gasket in groove in fitting. Install fitting in end plate and tighten securely.

5) On Cadillac and Studebaker, install poppet return spring with small end down, retainer and snap ring in control valve body. Install new filter, screen and outer snap ring.

6) On Chevrolet and Ford, install poppet return spring with small end down, gasket, end cover with air inlet tube, and secure in place with snap ring.

7) On all cars, place guide pins in control valve body screw holes in end plate (Guide pins can be made by cutting heads off three 8-32 x 2½" machine screws). Install gasket diaphragm, diaphragm spring (if so equipped), and control body on guide pins allowing cylinder tube to slide into connecting hose. *(CAUTION* —When assembling diaphragm, spring, and control valve body, extreme care should be taken not to distort the diaphragm when compressing the spring). Remove guide pins one at a time and install screws and lockwashers. Install hose clamps.

Cadillac Note—One side of valve body mounting flange is straight. This should be positioned next to hydraulic cylinder boss on end plate.

Hydraulic Cylinder Assembly: 1) Install new pushrod leather seal into end plate with lip of seal toward hydraulic cylinder side of end plate. Place end plate on bench and install stop washer with chamfered side down. Install seal cup with lip up and seal retainer with counterbored side next to cup (Cadillac & Studebaker), flat side next to cup (Chevrolet & Ford). On Ford and Chevrolet, next install spring with small end toward bore of end plate. (No spring on Cadillac and Studebaker). On all cars, next install stop washer and install snap ring in groove.

2) Place vacuum piston return spring over pushrod with small end of spring next to piston, carefully guide pushrod through seat in end plate. Compress spring. Use vacuum piston restraining strap or hook clamps to hold end plate and the cylinder together. Install ball, spring, retainer and snap ring in piston. On Cadillac and Studebaker, install deflector washer and nut.

3) Dip hydraulic piston cup in brake fluid and install in groove with lip of cup toward check valve end of piston. Dip hydraulic piston in brake fluid and assemble piston on push rod. Install retaining pin in hole in piston and rod. When pin is in position, retaining spring will hold it in position. Place end cap in vise and install bleeder screw, end cap gasket, hydraulic line connector with copper gaskets and retaining bolt.

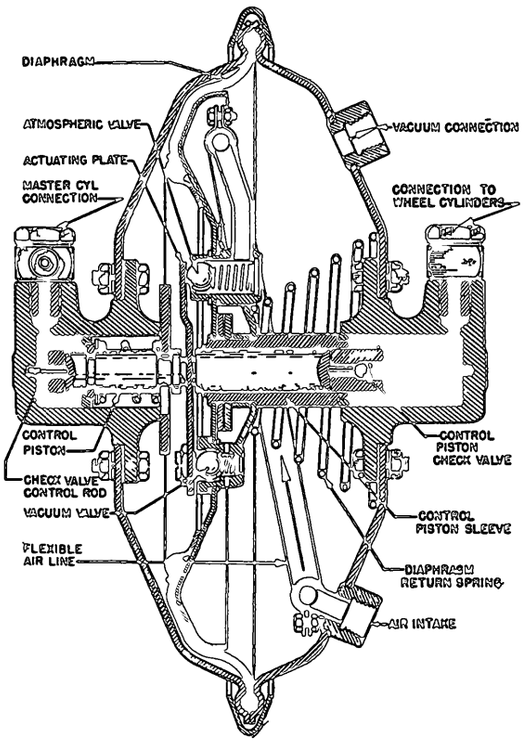
4) On 1955 Cadillac, 1955 Chevrolet 2nd Series Trucks, and Ford, install residual check valve, spring, spring seat, and snap ring.

5) Thread hydraulic cylinder into end cap with milled flats next to end cap, and securely tighten cylinder. Thread check nut on cylinder to limit of threads. Install hydraulic cylinder end seal against shoulder in end plate. Guide lip of piston cup into cylinder carefully, and threaded cylinder into end plate until cylinder bottoms firmly against end seal. Tighten cylinder until bleed screw on end cap is aligned with bleed screw in end plate and tighten check nut securely.

6) Remove piston retaining strap or clamps. Place rubber gasket in groove on end plate. Saturate cotton wicking by dipping vacuum piston in Shock Absorber Fluid, and allow excess oil to drain off. In addition, coat inside of cylinder shell lightly with shock absorber fluid. Insert piston into shell by tipping piston and gradually working it down into shell. Align scribe marks on shell and end plate (if made) and attach hook bolts. Tighten each bolt evenly until all bolts are uniformly tight.

Check Valve (Cadillac & Studebaker): Install end of spring over check valve ball. Install spring retainer plate with depression in plate in end of spring, install snap ring. Install plug in check valve body. Install fitting in bushing and install valve assembly in elbow on end plate.

INSTALLATION OF POWER BRAKE UNIT: Position power brake unit on mounting bracket and install lockwashers and nuts. Connect vacuum hose to check valve on power brake and tighten hose clamp. Connect brake line fittings to end plate. On Ford and Studebaker, connect stop light wires. On all cars, bleed system (see above).



VACDRAULIC POWER UNIT

Chrysler Crown Imperial, C40 (1946-47-48)

DESCRIPTION: Vacdraulic is a self-contained diaphragm type power unit connected in the hydraulic brake line between the brake master cylinder and the wheel cylinders. The diaphragm type power piston is mounted directly on the control piston sleeve within the vacdraulic housing and includes the control valves (atmospheric air intake valve and vacuum valve), valve operating mechanism, and manifold vacuum connection (flexible line from vacuum connection on housing to vacuum valve). A control piston is located within the power piston control sleeve. This piston is hollow to permit brake fluid to flow freely through the unit when brakes are off (ball check valve in end of piston is held off its seat by a control rod in this position) and has a rubber "piston ring" type seal at each end.

OPERATION: Vacdraulic unit is "vacuum suspended" type with vacuum on both sides of diaphragm when brakes are released (vacuum valve open, atmospheric valve closed) and entire power piston assembly is held in the off position by a large return spring in the housing. When brake pedal is depressed to apply brakes, fluid flows freely through the unit to the wheel cylinders (control piston check valve open). As pressure in brake lines increases, the control piston tends to move within the control sleeve, closing the vacuum valve and opening the atmospheric valve. Atmospheric air pressure acting on one side of the diaphragm causes the power piston sleeve to move with the control piston to force fluid out through the lines to the wheel cylinders at a "boosted" pressure and with no loss of volume (check valve closes when piston starts to move). Whenever brake pedal movement stops (as when brakes held "on"), a balance is set up between the vacdraulic unit control piston and sleeve movement so that the atmospheric valve closes without the vacuum valve opening. This causes the power piston to remain stationary. When pedal released to release brakes, the vacuum valve opens and the return spring moves the power piston assembly to its "off" position. At this point the control piston check valve is positively opened by the rod to permit free fluid flow back to the master cylinder.

ADJUSTMENT: None required.

VACDRAULIC POWER BRAKE UNIT

CHRYSLER VACU-EASE BRAKE POWER UNIT

Chrysler Six & Eight (1949-54)
DeSoto Six (1950-54), Eight (1952-54)
Dodge Six (1950-54), Eight (1953-54)

►*PRODUCTION CHANGE NOTE:* Two types used.

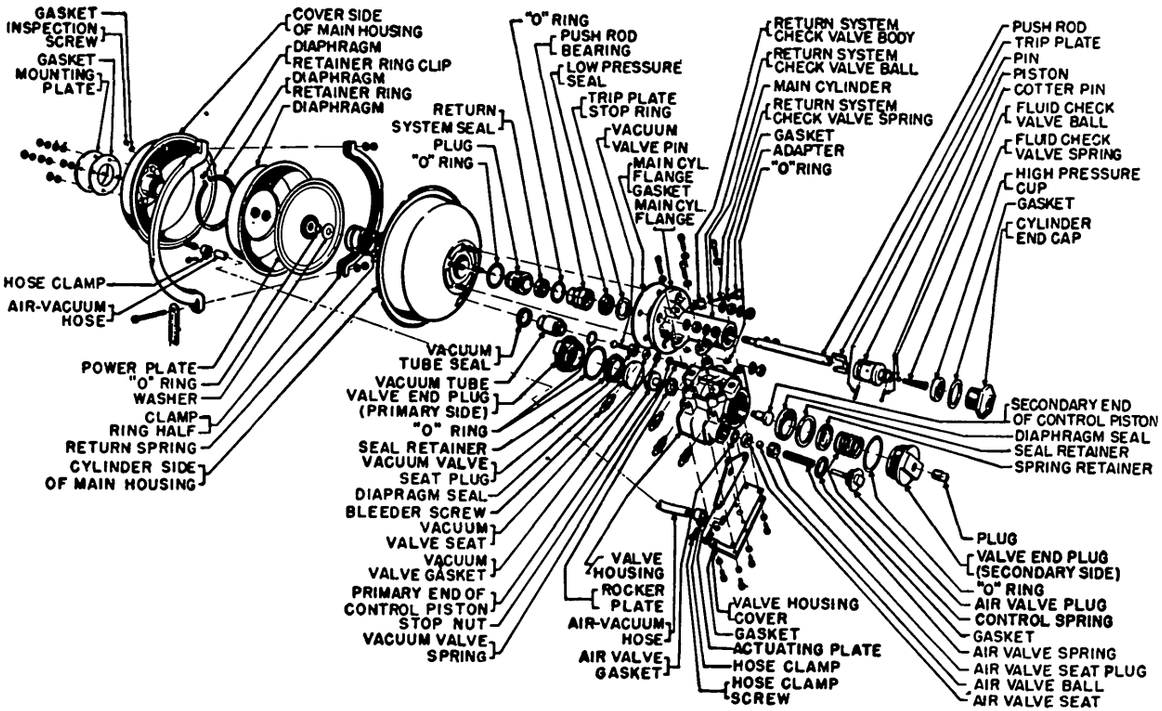
Internal Valve—1949 and Early 1950.

External Valve—Late 1950-54.

DESCRIPTION: Internal Valve Type—This unit is similar in construction to the Vacdraulic Power Unit. Primary and secondary cylinders can be removed without disturbing the diaphragm housing, Fluid return system has outside cross-over line.

External Valve Type—The valve housing and cylinder unit are mounted as an assembly on one end of the main diaphragm housing. The valve housing assembly controls the relative air pressures on both sides of diaphragm. Fluid return system built-in. NOTE—The External Valve Type unit can be used to replace the Internal Valve Type by using an Adapter Kit, Chrysler Part No. 1321149.

ADJUSTMENT: None required.



►*CAUTION:* Repair of the vacuum and air valves in the field is not recommended by the manufacturer, since these parts are specially calibrated.

INTERNAL VALVE TYPE UNIT OVERHAUL: All that is generally required is a minor overhaul as follows. ***Cleanliness is extremely important.***

Disassembly: After removing the unit from the car tape up the air and vacuum connections to keep out dirt. Remove the cross-over line and cylinder end caps. Mount the unit, primary end down, on a box or a short length of 4" pipe. Remove 4 nuts holding the secondary cylinder to housing. Remove cotter pin, fluid check valve ball, spring, and trip rod. Remove the cup retainer washer, secondary cup and spring. Remove the fluid seal with a hook, being careful not to scratch the control piston. Invert the unit and remove the primary cylinder. Remove the snap ring, cup retaining washer, primary retaining cup and piston ring. Using pliers and screwdriver remove the annealed ring from the end of the piston being careful not to damage the ring groove, and remove the seal with a hook. Examine parts for scores, chipping, or out-of-round. Always replace the cups and seals regardless of condition. Cylinders should be mirror smooth. Light scratches can be smoothed out with crocus cloth, but badly scored cylinders must be replaced.

Diaphragm Unit—To examine the diaphragm with the unit disassembled as above, mark both halves of the diaphragm housing, remove the clamp ring and unfasten the housing keys. Maintain pressure on the housing to keep the return spring under control. Housing should be dry inside. If wet with fluid, seals are leaking. Check diaphragm for cracks or leaks. When installing a new diaphragm, fit it snugly to the power piston flange, with the nub on the diaphragm fitting into the locating hole in piston. Connect hose to valve and inlet connections, holding power piston and diaphragm assembly so that locating tab on diaphragm is lined up with the locating slot in housing. This will prevent twisting the hose when assembling. Place housings together and install clamp ring, tapping ring all around with a rawhide mallet to seat ring, tighten all nuts.

Reassembly: Install the secondary end first. Lubricate the control piston and seal with silicone grease or castor oil. NOTE—The secondary seal has a ¾" inside diameter and the primary seal ½" inside diameter. Install the seal in the cylinder seat with the metal case down, lip up. Slide the piston ring, cup (with lip up), and retaining washer onto the end of the control piston. Drop the valve check ball into the end of the piston and install the ball spring (small end to ball). Install spring retaining cotter pin. Install new cylinder flange gasket, and apply a small amount of brake fluid on the cylinder wall and outer lip of the secondary cup. Install cylinder, aligning the elbow fitting with the inlet tube on housing. Install mounting nuts. Reach underneath and press the power piston up toward the secondary end to align the cylinder. Release the piston and tighten the cylinder nuts evenly to 150 inch pounds torque. Invert the unit and lubricate the piston and seal with silicone grease or castor oil. Install seal, with metal case down (lip up). Install annealed retaining ring in groove, using the minimum amount of pressure possible to close the ring. Install the primary piston ring, cup (with lip up), retaining washer, and snap ring. Lubricate cylinder wall and primary cup outer lip with brake fluid and assemble the primary clyinder as given for the secondary cylinder. Install trip rod in center of the control piston, insert copper gasket, trip rod stop plate, cap copper gasket, and cap. Mount the unit with the cap in the vise and tighten the other end cap to 80 ft. lbs. torque.

VACU-EASE BRAKE POWER UNIT (EXTERNAL VALVE TYPE)

EXTERNAL VALVE TYPE UNIT OVERHAUL: After removing the unit from the car, proceed as follows. ***Cleanliness is extremely important.***

Disassembly: Clamp unit in vise (grip four mounting screws). Loosen cylinder end cap and clamp on hose. Remove four Allen head screws holding valve housing to cylinder, and remove housing. Invert the unit, mark both halves of housing, remove clamp ring and disassemble cover side of main housing from cylinder side. Remove hex nut from center of power plate and lift off plate and diaphragm assembly. Remove small "O" ring and washer from end of push rod and remove return spring. Remove the four cylinder-to-main housing nuts, and remove cylinder. Clamp cylinder in vise with push rod end up. Screw special protective "thimble" (included in repair kit) on threads of push rod end, unscrew return system seal retaining plug and remove it. Pull the push rod out of the cylinder. Remove cylinder end cap and examine cylinder walls. Remove light scratches with crocus cloth, and clean with alcohol. Replace badly scored cylinders. Remove cotter pin, fluid check valve ball and spring, and bronze bearing from push rod.

Reassembly: Remove secondary cup from piston being careful not to scratch the anodized aluminum surface, and replace with a new one. Drop check valve ball in piston, install ball spring (small end to ball) and install cotter pin. Lubricate piston and cylinder with brake fluid, insert push rod and piston assembly from cap end of cylinder. Install cylinder cap with new copper gasket, finger tight. Clamp cylinder, push rod end up in vise, and install stop plate washer. Remove primary cup from inside

CONTINUED ON NEXT PAGE

VACU-EASE POWER UNIT (Continued)

bronze bearing, and "O" ring from outside of bronze bearing, and replace with new cup and ring. Lubricate bronze bearing and slide into cylinder over push rod with primary cup down. Press down lightly with thumb. Lubricate inner lip of retaining seal, slide seal and plug assembly over end of push rod. Screw retaining plug into cylinder and tighten. Place cylinder in vise and tighten end cap to 110 ft. lbs. torque. Remove special thimble nut from threads on push rod. Replace "O" ring seal, and cylinder flange gasket between cylinder and main housing. Remove cylinder from vise and assemble to main housing with flat side of cylinder facing the short studs. Install lock washers and nuts and tighten to 150 ft. lbs. torque. Clamp assembly in the vise with push rod end up, and install flat washer first, and a new small "O" ring on end of push rod. Install spring in boss of power plate and press plate and diaphragm down over end of push rod against spring. Secure assembly to push rod with nut and lock washer tightened to 40 inch pounds torque. Assemble the two halves of the housing (lining up marks). See that cross-over tube rests in slot in cylinder side of main housing. Install clamp ring. Tighten clamp ring bolts, being careful to center cross-over line between ears of clamp ring. Pull vacuum tube out of valve housing and replace "O" ring and rubber grommet. Lubricate "O" ring only, and re-install vacuum tube, "O" ring first, into valve housing. Replace "O" rings used between valve housing and cylinder. Reconnect housing hose. Fasten the valve housing to cylinder.

TROUBLE SHOOTING: **Brakes do not Release Properly**—With engine running, check the brakes for release. If not released, crack line from master cylinder to power unit. If this releases brakes, trouble is not in power unit. If brakes not released, crack hydraulic line at end of cylinder of power unit (line between power unit and wheel cylinders). If this releases brakes, power unit is at fault (missing inspection screw or gasket on main housing cover).

Unit does not Boost: With engine running, press the pedal down and listen for a rush of air through the power unit air cleaner. If no rush of air is heard, check if vacuum is present at the unit by disconnecting the line. If no vacuum is reaching the unit, check for plugged line, or defective vacuum check valve (at the engine manifold). If a rush of air is heard at the unit air cleaner when the pedal is depressed and booster still is inoperative, it indicates the fluid check valve is not seating properly. If with engine running, a continuous rush of air is heard, without operating the brake pedal, it indicates the diaphragm punctured or cross-over line between valve housing and cover is leaking.

1955 CHRYSLER, DE SOTO, DODGE, PLYMOUTH POWER UNIT

Chrysler & Imperial (1955)
DeSoto (1955)
Dodge (1955)
Plymouth (1955)

DESCRIPTION: Integral type, self-contained, vacuum-suspended, power braking device using engine intake manifold vacuum and atmospheric pressure for its power. Unit incorporates air-vacuum housing, hydraulic cylinder, fluid reservoir, air cleaner, and vacuum check valve. Unit is mounted on dash above brake pedal.

OPERATION: With engine running, brakes unapplied, both sides of power piston are under a vacuum. Application of brake pedal causes atmospheric port to open, forcing power piston forward and thereby exerting a thrust on hydraulic plunger. This increases line pressure to the four wheels. Release of brake pedal restores vacuum balance in power cylinder.

CHECKING & ADJUSTMENT: Check all parts of the power brake system before disassembling the Power Unit whenever brake trouble experienced.

Adjustments: No adjustment of Power Unit for free play or return stop is required. Unit has built-in pedal return spring and a pedal return stop. Pedal height and travel are determined by the combined length of the pushrod and pushrod end (clevis) which are adjustable.

Pedal Height & Travel Adjustment (Unit on Car)– Slide scale next to boot, inside of pedal bracket up to and against dash panel, and measure distance back to center line of clevis pin. Distance should be 8 57/64" (Chrysler), 8 23/32" (Others). If not, re-adjust clevis on rod, re-tighten clevis jam nut and re-check dimension.

Pedal Height & Travel Adjustment (Unit Off Car)– Measure from reinforcing plate mounted on unit to center line of hole in rod end (clevis). Dimension should be 8 61/64" (Chrysler), 8 25/32" (Others).

▷*PEDAL ADJUSTMENT NOTE:* It is suggested that for greatest braking efficiency, driving ease, and comfort, that brake shoes be kept well adjusted to maintain maximum pedal reserve with brakes applied.

BLEEDING BRAKES: Using a pressure bleeder attached to fluid reservoir of unit, bleed system from bleeder screw immediately forward of the reservoir on top of hydraulic cylinder of unit, then at the four wheel cylinders. When fluid runs clear at all points, start engine, pump brake several times, and then re-bleed system. After bleeding completed, check for leaks in brake system while applying heavy brake pressure with engine running. *NOTE*–After bleeding system, fill reservoir to no higher than 1/8" below filler cap neck.

LUBRICATION: Check level of brake fluid in reservoir every 1000 miles. Fill reservoir to no higher than 1/8" below filler cap neck.

TROUBLE SHOOTING: Before checking power brake unit for source of trouble check remainder of brake system.

Pedal Fails to Return: Overall width of pedal hub plus nylon bushing flanges exceeds length of pedal pivot spacer pinching the hub and bushings; bind of nylon bushings.

Brake System Loses Fluid: Loose or broken connections in brake hydraulic system; worn or damaged primary cup, primary cup seal and dome cup.

Brakes Do Not Release Properly: Pedal fails to return properly; plugged compensating holes in power piston sleeve; damaged or weak power piston return spring, air valve control spring, or reaction spring; excessively dry air valve "O" ring; brakes improperly adjusted; insufficient brake fluid in system; dust boot retainer on air cleaner cover is not concentric with power piston guide sleeve.

Unit Does Not Boost: (*NOTE*–To determine if unit operating, test as follows: With engine stopped, depress brake pedal several times to eliminate all vacuum from system. Apply brakes, and while holding foot pressure on brake pedal, start the engine. If unit operating, pedal will move forward when engine vacuum power is added to pedal pressure). Possible causes for brake not boosting: Bent, broken or obstructed vacuum source line from engine manifold to check valve, or a faulty vacuum check valve; blocked air passage in power piston guide sleeve or in air cleaner element; jammed air valve seat assembly in power piston due to foreign material becoming lodged in power piston air valve seat bore cavity; damaged secondary cup.

Loss of Pedal: Dirt or foreign material lodged between outside lip of secondary cup and cylinder bore.

Brakes "Touchy" or "Grabby": Inspection screw missing on air side of diaphragm; grease, fluid or moisture on brake linings; brakes improperly adjusted.

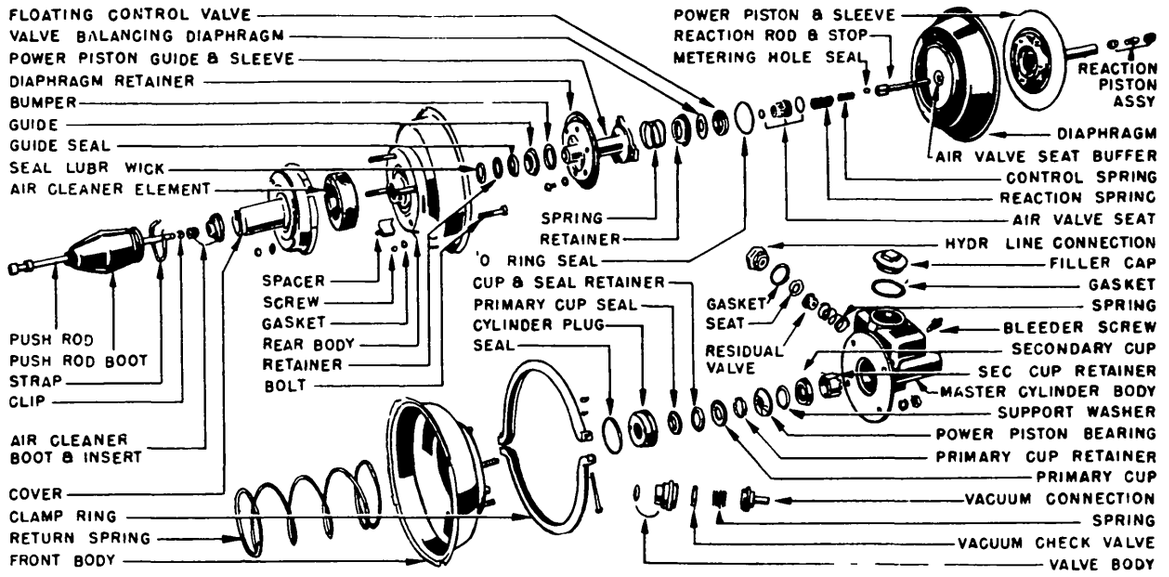
"Spongy" Pedal: Air in brake lines or in hydraulic cylinder on power unit.

Pedal Travel Too Great: Improperly adjusted brakes; air in brake system.

REMOVAL & INSTALLATION: Remove clevis pin attaching pushrod to power lever. Disconnect hydraulic line at power brake unit. Disconnect vacuum line at power brake unit. Disconnect stop light switch wires. From passenger compartment side, remove nuts from power brake unit two lower studs which extend from power brake unit through dash panel and pedal mounting bracket. Then remove four nuts on engine side of dash panel which hold reinforcement to dash panel. This will allow removal of reinforcement and power brake unit as an assembly. Remove power brake unit assembly from reinforcement by removing two upper stud nuts. At same time, this allows air cleaner cover and air cleaner to be removed. To install, reverse removal procedure. *NOTE*–Before reinstalling unit on car, check brake pedal linkage for freedom of movement. Refill master cylinder.

OVERHAUL: *NOTE*–After removing brake unit and before starting disassembly operations, remove reservoir filler cap and gasket, pour out brake fluid and discard it. Stroke unit at least two applications to dissipate vacuum and to pump out as much of remaining fluid as possible through wheel cylinder connection. Stop light switch in boss on bottom of hydraulic cylinder should not be removed except for replacement or to correct a fluid leak.

CONTINUED ON NEXT PAGE



1955 CHRYSLER, DESOTO, DODGE PLYMOUTH POWER UNIT (Cont.)

Disassembly: Major Components–Remove pushrod from unit by sliding pushrod boot down on rod and clamping end of pushrod in vise, then, gripping lower unit firmly, pull it away from pushrod with a quick jerk. *(NOTE–* Pushrod is held in place by pushrod retainer clip, which cannot be re-used. Whenever pushrod removed from unit, new retainer clip must be used at reassembly). Open boot retainer strap and remove pushrod boot and air cleaner cover boot Discard retainer strap Clamp unit in vise with hydraulic cylinder end down. Vise should be clamped on hydraulic cylinder only tightly enough to hold securely, clamping too tightly will crack or distort cylinder Remove reinforcement plate, then air cleaner cover assembly by removing four hex nuts and lockwashers. With cover assembly removed, lift out four spacers and air cleaner core. Disassemble body assembly by removing two clamp rings. To facilitate correct reassembly, loosen both clamp ring screws but remove only one, keeping the two clamp ring parts held together in their proper relationship. *(CAUTION–* Be sure to lift straight up while holding power piston guide sleeve down against return spring. Valve side of body assembly should slide straight up and off of power piston guide sleeve). Remove power piston and guide assembly from body assembly by lifting straight up This is important to prevent damage to power piston sleeve and bearing. If edge of diaphragm did not free itself from flange of body assembly, hold power piston and guide down against return spring while loosening edge of diaphragm Then allow return spring to lift power piston and guide assembly. Remove return spring. Remove hydraulic cylinder assembly off of body assembly Remove and discard cylinder-to-body seal

Body Assembly (Cylinder Side)– Remove vacuum check valve assembly, then remove and discard check valve-to-body "O" ring. Position check valve assembly in vise clamping on large hex on body, to remove check valve body cap. Lift out check valve spring and floating valve assembly, but **do not** discard spring.

Body Assembly (Valve Side)–From hub of body assembly, valve side remove and discard guide seal and seal lubricating wick This can be done with small pointed pliers, using care not to damage guide bearing or wick retainer. Examine inspection screw and gasket, remove only if damaged or not sealing properly.

Power Piston & Guide Assembly–Place power piston and guide assembly in holding fixture, with power piston and guide end up. Lift guide return bumper from guide sleeve, and discard, but note its thickness It is important that the new bumper be the same thickness as the one removed (Except on very early production, the thicker bumper is smooth on both sides). Remove diaphragm retainer and diaphragm. Lift guide assembly off of power piston assembly, and remove and discard "O" ring seal from between these two assemblies. Remove and discard floating control valve assembly, and valve balancing diaphragm, but **d not** discard spring, or spring retainer. With power piston assembly still in holding fixture, lift out air valve seat assembly and discard. Lift out control spring and reaction spring. Lift out reaction rod assembly. Remove and discard metering hole seal and buffer. Remove power piston assembly from holding fixture, insert a drift pin into center of power piston, and push out reaction piston insert and dome cup assembly. Using extreme care to avoid marring reaction piston or dome cup insert, remove and discard reaction cup. Reaction piston and cup insert can be popped out of cup by pinching dome between thumb and forefinger.

CHRYSLER, DE SOTO, DODGE, PLYMOUTH BRAKE POWER UNIT

Hydraulic Cylinder Assembly–Place cylinder assembly in vise with flange end up. Do not clamp tightly. Using a face spanner wrench, remove cylinder plug assembly Disassemble cylinder plug assembly by hand by removing primary cup, retainer and primary cup seal from cylinder plug Primary cup is easily removed by gripping inner cup lip between thumb and forefinger. Discard cup and seal, **do not discard retainer.** From hydraulic cylinder, lift out primary cup retainer, power piston bearing, and secondary cup support washer. Then remove secondary cup only and lift out secondary cup retainer. With cylinder clamped in vise, remove secondary connection plug, and residual check valve seat. Then lift out residual check valve assembly and valve spring. Discard residual check valve assembly and seat

Cleaning & Inspection: Before any part of unit is reassembled, all metal parts must be thoroughly cleaned with diacetone alcohol or clean brake fluid and wiped dry. Avoid allowing dirt or grit to get into unit during reassembly. When assembling unit, be sure to discard all parts specified and other damaged parts, replacing them with NEW, clean parts.

Reassembly: Hydraulic Cylind r Ass mbly–1) Position hydraulic cylinder in vise with secondary connection boss facing up. Insert residual check valve spring and new residual check valve assembly. Place new residual check valve seat on residual check valve; center carefully. Assemble secondary connection plug and new gasket to hydraulic cylinder. Torque to 125 ft. lbs. Position hydraulic cylinder in vise with flange end up, and wet inside of cylinder with brake fluid. Then insert secondary cup retainer, small end up, being sure that it rests evenly on hydraulic cylinder bore. Then, after wetting new secondary cup with brake fluid, insert it into cylinder. Cup lips must be down, be sure that cup lip is not turned back at any point as cup slides into cylinder. Place secondary cup support washer in position on secondary cup.

2) Insert power piston bearing into cylinder on top of secondary cup support washer. Notched face of bearing must face up, and bearing must be centered in cylinder bore Place primary cup retainer, notched edge down in hydraulic cylinder, centering it on notched surface of power piston bearing *(This is v ry important).* Be sure that retainer is centered as closely as possible by eye, so it will not be damaged when cylinder plug assembly is installed.

3) Assemble cylinder plug assembly by inserting new seal, seal retainer flat side out, and new primary cup in that order. Both seal and cup must enter plug with lips facing out. Use finger to force outside lip of both seal and primary cup down and outward against bore of plug to insure sealing contact. Install cylinder plug assembly into hydraulic cylinder using a face spanner wrench. Torque to approximately 25 ft. lbs.

Guide Assembly–Inspect end of guide casting where it seats against air valve seat assembly. This must be smooth and clean. Position guide assembly in holding fixture with sleeve end down. Then assemble new valve balancing diaphragm on new floating control valve–after wetting outside diameter of diaphragm slightly with hydraulic brake fluid. Press spring retainer over diaphragm and floating valve assembly, us-

CONTINUED ON NEXT PAGE

1955 CHRYSLER, DESOTO, DODGE PLYMOUTH POWER UNIT (Cont.)

ing thumb pressure only. Then wet inside diameter of diaphragm slightly with hydraulic brake fluid and place spring on retainer. Press complete assembly down on power piston guide stop. Also install new power piston-to-guide "O" ring seal on power piston guide hub.

Power Piston & Guide—1) Assemble stainless steel reaction piston into bronze dome cup insert. Small diameter of bronze insert must be toward spherical end of reaction piston.

2) Assemble new pre-greased dome reaction cup over spherical end of reaction piston and insert assembly. Force cup back firmly to insure snug fit of cup bead in groove of insert. Place power piston and sleeve assembly on bench, sleeve end up, and after lubricating outside diameter of reaction cup with brake fluid, press reaction piston, insert end dome cup assembly into power piston sleeve, dome out. Use care to avoid damaging cup. Press down into sleeve firmly until it bottoms. Check to be sure that outside diameter of reaction cup is not obstructing compensating ports, and that all these port holes are open and clean.

3) Assemble new buffer and new metering hole seal to reaction rod and stop assembly. Invert power piston and sleeve assembly and place it holding fixture, sleeve end down, then drop complete reaction rod assembly into center of power piston.

4) Place reaction spring in center of reaction stop cavity, and control spring around outside of reaction stop, in power piston cavity.

5) Install new air valve seat "O" ring seal in groove on outside diameter of new air valve seat assembly using care to preserve silicone grease on seal (This seal is supplied pre-greased in cellophane envelope in kit).

6) Install complete air valve seat assembly in center of power piston cavity, over control spring reaction spring and reaction rod stop. Use a twisting motion as seal enters bore of power piston. Then use thumb pressure to test air valve seat springs for freedom of movement, *(NOTE*—Air valve seat is steel, power piston cavity is aluminum casting; use extreme care to avoid any damage or marking, especially on aluminum vacuum valve seat.).

7) Position diaphragm retainer over guide and sleeve assembly, with three of the six holes in the retainer lined up with three holes in guide. Position diaphragm on flange of power piston and sleeve assembly with flange of diaphragm down. Be sure that inside diameter of diaphragm is nested snugly all around in groove of power piston flange.

8) With power piston diaphragm retainer and guide assembly held directly above power piston assembly, insert pushrod without retaining clip through center bore of guide and into pushrod cavity in center of air valve seat assembly. Then, holding air valve seat down against control and reaction springs, position guide assembly so that three holes in guide line up with three holes (tapped) in power piston. Be sure that "O" ring seal is properly positioned between guide and power piston.

9) Install three lockwashers and hex bolts through holes in diaphragm retainer and into tapped holes in power piston. Tighten all three bolts evenly to torque of 90-100 **in. lbs.** Using pushrod, check for freedom of movement of air valve seat against control and reaction springs.

10) Place new rubber guide return bumper over guide sleeve and press firmly down on hub of guide. *NOTE*—A kit, available from Chrysler Corporation Parts Division, contains two guide return bumpers, each of a different thickness. It is important to install the bumper which is the same thickness as the one that was taken out of unit at disassembly.

Body Assembly (Valve Side)—With body assembly, valve side resting on bench, hub end up, insert new guide seal into hub, being sure that lips of seal are facing up, away from bearing, and that seal is installed between bearing and wick retainer which is inside hub. *(NOTE*—Seal will slip easily into place if held between thumb and forefinger, in an elliptical shape and inserted through hub of body. This seal is supplied pre-greased in a cellophane envelope in the repair kit). Insert new wick into hub in same manner as seal was inserted, using care to preserve grease on wick. After wick installed, be sure that wick retainer is positioned snugly against wick and away from cup lips. Apply any grease remaining in seal and wick envelopes to inside of hub, to provide maximum lubrication for seal, wick, and guide bearing. Check inspection screw and gasket to be sure they are tight.

Body Assembly (Cylinder Side)—Position vacuum check valve body in vise and insert new floating valve assembly, being sure that bonded rubber seal is facing down, against seat. Then assemble spring and cap.

Reassembly of Major Components—1) Place new cylinder-to-body seal in groove around cylinder plug assembly, being careful to avoid twisting seal.

2) Assemble hydraulic cylinder assembly to body. Position cylinder on body in such a way that, when viewing assembly from cylinder end, vacuum check valve is to left of hydraulic cylinder. Then assemble hex nuts and lockwashers to studs, finger tight only.

3) Position cylinder assembly with body assembly, cylinder side, in vise with cylinder end down and body assembly flange facing up. Place return spring in body assembly, centering it around cylinder plug assembly and inside the four cylinder flange bolt heads in housing.

4) Assemble power piston and guide assembly to body assembly, valve side, by inserting guide sleeve through hub of body assembly. Be careful to avoid damaging felt wick in hub.

5) Hold assembled power piston and guide assembly and body assembly, valve side, by guide sleeve, which now protrudes out of hub of body. Wipe power piston sleeve with brake fluid, then carefully position power piston on return spring so that spring nests around shoulder of power piston.

6) Press power piston and guide assembly down into unit against return spring, watching to avoid misalignment as power piston sleeve enters bore of cylinder plug assembly. Holding power piston and guide down against spring, place edge of diaphragm in groove on flange of body assembly, valve side, over edge of diaphragm and flange of body assembly, press firmly into position.

7) With two sides of body assembly properly mated, place two half-ring clamps over body flanges, being sure that flat portion of rings match cutaway portions of body flanges. Fasten half-ring clamps with two clamp ring screws, lockwashers and hex nuts. Tap ring clamps snugly into place with a rubber mallet, then tighten securely. "Do Not Lubricate" tag should be attached on either side of unit, under one of these two nuts. *(NOTE*—Two sides of body assembly must be assembled so that notches on one side mate with keys on other, and the cutaway portions of the flanges match).

8) Press power piston and guide assembly down as far as possible against return spring three or four times to be sure that power piston sleeve and hydraulic cylinder are properly centered. Remove unit from vise, invert, and while holding unit down to push power piston and guide assembly into fully applied position, tighten evenly the four cylinder flange nuts, using a torque of 180-200 **in. lbs.** After all flange nuts are tight, power piston and guide assembly must return freely to "off" position as soon as pressure is released. If power piston does not return freely, loosen cylinder flange nuts and re-align cylinder to housing; then retighten nuts and test again for free return.

9) Return unit to vise then blow out or replace air cleaner core, centering it around hub of body assembly. Then place one spacer around each of four mounting bolts.

10) Assemble air cleaner cover assembly to unit over air cleaner core and spacers, position cover so that air inlets will face down when unit is mounted in position on vehicle. Assemble reinforcement plate to unit over air cleaner cover assembly, positioning plate so that its longest dimension will be below unit when mounted in position on vehicle. Install four lockwashers and hex nuts and tighten securely to torque of 180-200 **in lbs.** Be sure guide sleeve and air cleaner cover sleeve are concentric. If necessary, tap cover sleeve lightly with rubber mallet to align.

11) Insert pushrod into pushrod boot, then into air cleaner cover boot, and insert assembly and snap NEW pushrod retainer clip into position on small end of pushrod. Be sure that small end of boot is nested snugly in groove on outer end of pushrod.

12) Holding boots back toward outer end of pushrod, press pushrod with retainer clip straight down through center of guide sleeve and into air valve seat cavity. Exert approximately 40 lbs. of pressure until end of pushrod snaps into place. When properly installed, pushrod is held securely enough in place so that it can be used to lift the weight of the unit.

13) Fit boots on flange of sleeve of air cleaner cover assembly, first the boot cover assembly, then the pushrod boot, being sure that they fit snugly. Then install new boot retainer strap. Reinstall bleeder screw and reservoir filler cap and gasket. Also reinstall stop light switch if it has been removed. Be sure all are in position and secure before reinstalling on vehicle.

MIDLAND POWER UNIT

Ford Trucks (1948-55)
Ford Passenger Cars (1954-55)
Ford "Thunderbird" (1955)

►CHANGES & CORRECTIONS

►*1955 500 & 600 SERIES TRUCK BRAKE PEDAL "KICK-BACK" CORRECTION:* An improved design brake booster hydraulic cylinder spring retainer has been released to prevent possibility of brake pedal "kick-back" This retainer has same number as earlier type (TEAA-2423-A) but is identified by code number (8-55) to right of word "retainer" on package

DESCRIPTION: Consists of a vacuum power chamber, hydraulically actuated vacuum control valve, and an hydraulic slave cylinder, all in a single sealed unit.

OPERATION: With engine running, brakes released, power diaphragm is vacuum suspended. Depressing pedal causes fluid to pass from master to slave cylinder, moving control valve piston, which admits atmospheric pressure to front of diaphragm As pushrod moves, check valve seals fluid in slave cylinder and hydraulic line pressure builds up to operate brakes

REMOVAL & INSTALLATION: Depress pedal a few times to relieve vacuum. Remove lines and attaching bolts To install, reverse removal procedure.

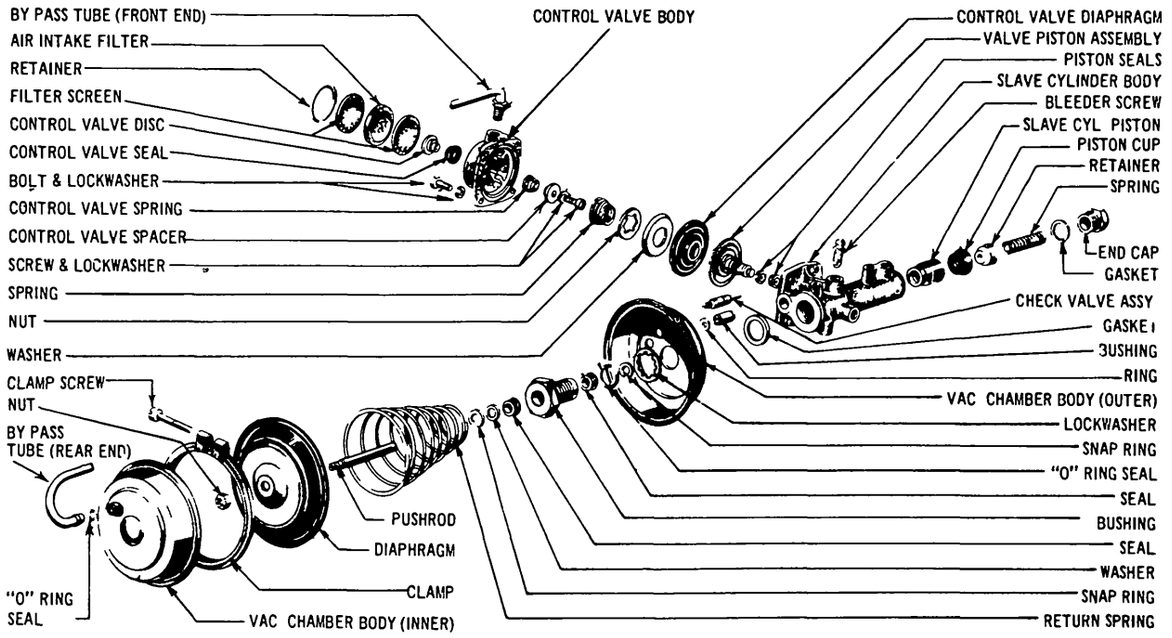
TROUBLE SHOOTING: Brake Pedal Kicks Back—Engine Running—Slave piston cups leaking, hydraulic check valve leak, intermittent vacuum leak in unit

Brakes Do Not Release—Engine Running: Control valve piston sticking, hydraulic (slave piston) sticking, valve spring broken, diaphragm body leaking

Vacuum Leak With Brakes Released—Engine Idles Normally: Defective "O" ring seal or body-to-slave cylinder gasket, dirt or worn atmospheric valve seal, defective or dirty vacuum check valve.

Vacuum Leak With Brakes Released—Rough Engine Idle: Leaking diaphragm in vacuum chamber, leaking control valve piston or diaphragm; leaking control valve vacuum valve seal.

Hard Pedal—Indicating Inoperative or Weak Booster: Clogged air cleaner element, sticking hydraulic (slave) cylinder piston, air leak at atmospheric valve seal, control valve diaphragm, control valve piston, or power chamber diaphragm.



OVERHAUL: *TRUCK NOTE*—Do not remove breather in cab or controls mounted in engine compartment unless operating conditions indicate repairs are necessary.

Disassembly: 1) Remove control valve bypass tube from control valve and the body. Remove stop light switch. Mark both halves of body with a scriber, then mark flanges of control valve and slave cylinder so parts can be assembled in their original positions

2) Remove clamp then remove outer body and the diaphragm and pressure plate assembly with return spring. Remove vacuum check valve from inner body

3) Remove retainer and air intake hose fitting (or snap ring, screens, and filter) from control valve body. Remove control valve to slave cylinder attaching bolts and lockwashers Lift the control valve body, diaphragm spring, and the control valve piston and diaphragm assembly from slave cylinder body

4) Remove pushrod bushing, lockwasher, inner body, and gasket from slave cylinder body Remove transfer bushing and "O" ring seal from cylinder body.

TYPICAL MIDLAND BRAKE POWER UNIT

5) Remove end plug or cap, gasket, return spring and retainer, from end of slave cylinder. Remove slave cylinder piston cup and piston from cylinder. Remove inner and outer pushrod bushing seals.

6) Remove inner and outer seals from control valve piston. Remove control valve diaphragm plate and retaining nut by prying inner tangs of nut away from piston shaft. Separate the control valve disc and spacer by removing attaching screw and lockwasher. Then remove disc, seal, spring, and spacer from control valve body. Remove check valve retainer, check valve and return spring as an assembly from slave cylinder piston. Remove pushrod from diaphragm and disassemble check valve.

Inspection: Wash all metal parts in brake fluid and dry thoroughly. Use air to dry all internal passages. Replace all worn or damaged parts and if slave cylinder bores or control valve plunger show wear or evidence of corrosion, the slave cylinder body should be replaced. Replace pushrod if rough or damaged. If control valve seat is worn or damaged, replace control valve body.

Reassembly: 1) Assemble diaphragm on pushrod. After nut is tightened, coat threads with shellac to prevent leakage. Assemble control valve disc, seal, spring, and spacer in the control valve body with screw and lockwasher. Position control valve diaphragm and plate on control valve, and secure diaphragm and plate solidly in place with nut. Install control valve piston seals on piston

2) Insert check valve spring and valve and retainer in slave cylinder piston. Be sure check valve floats freely and does not bind in bore. Install the inner and outer pushrod bushing seals, and secure them in place with the retainers.

3) Coat the piston bores in slave cylinder body with hydraulic fluid. Dip slave cylinder piston, seal, retainer, and spring in fluid. Install piston in bore with recessed end toward pushrod bushing end of body Carefully position seal and retainer on top of piston Insert spring in retainer, and secure it in place with end plug or cap, using new gasket.

4) Place new gasket and inner body of vacuum power chamber on slave cylinder body. Make certain transfer bushing and "O" ring are in place before inner body is installed on cylinder body. Install pushrod bushing lockwasher over end of bushing. Thread bushing in place, be sure inner body seats squarely on cylinder body, then tighten bushing securely.

5) Dip control valve piston in hydraulic fluid, then install control valve. Position control valve spring on control valve diaphragm with small end of spring on diaphragm plate. Position control valve body over spring, align the scribe marks, then install control valve body-to-slave cylinder body attaching bolts and lockwashers. Tighten bolts solidly. Install air intake hose fitting (or screens, filter, and snap ring) on control valve body.

6) Place small end of diaphragm return spring on top of pushrod bushing. Carefully insert end of pushrod into bushing. Align diaphragm plate on large end of spring. Place outer body of vacuum power chamber on top of diaphragm with marks in alignment. Install clamp, making certain diaphragm head is properly positioned between two halves of chamber, then tighten clamp screw firmly.

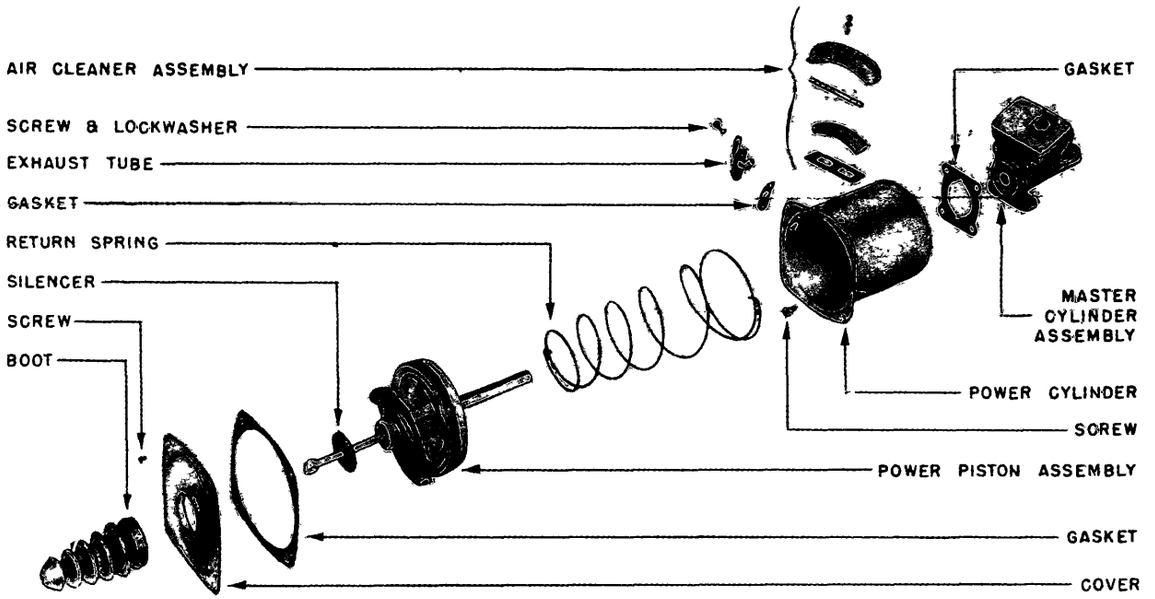
7) Assemble check valve, then install it in inner body of chamber. Install a new seal on slip end of bypass tube, then install tube in outer body of chamber and control valve. Tighten nut on control valve body firmly.

MORAINE POWER UNIT

Buick (1955)
Oldsmobile (1955) ①
Pontiac (1955) ①

①—Bendix Brake Power Unit also used.

►CHANGES, CAUTIONS, CORRECTIONS



►*1955 BUICK CHECK VALVE NOISE CORRECTION (Caused by Vacuum Leak Between Check Valve & Vacuum Tank or in Check Valve):* (*NOTE*—Check valve chatter may be caused by riding brake pedal causing drain on vacuum supply). Make vacuum check, after making sure that brake pedal is in fully released position, properly adjusted and with no binds in it, and that the check valve is free of foreign material and operates freely. If vacuum assist still not obtained, replace check valve (NEW Part No. 5455046) as follows: Remove vacuum line from check valve to "T" connection. Remove cap from old valve body and remove spring and valve (*NOTE*—Leave valve body attached to frame). Discard valve and spring. Cut vacuum pipe just ahead of first bend (From "T" connection end). Install 3/8" pipe flare nut, flare pipe. Install new valve on end of pipe that was just cut off and flared. Replace old valve cap (without spring and valve). Install new valve and vacuum line as an assembly and make sure hose at "T" connection makes sufficient contact with new valve. Recheck vacuum assist.

►*1955 BUICK HYDRAULIC PISTON REACTION PLATE INSTALLATION CAUTION:* If reaction plate installed backwards, faulty brake operation will result and it will be difficult to select proper number of shims (See Overhaul below). Reaction plate should have concave side of rim toward shoulder of piston and rounded side of rim against reaction levers.

►*1955 PONTIAC MASTER CYLINDER SECONDARY CUP EXPANDER ASSEMBLY PRODUCTION CHANGE:* New finger type expander and spacer assembly, Part No. 5454862, now used in production, and replaces spring loaded expander used on early cars. Finger type expander requires a new spacer (identified by black oxide finish). *NOTE*—It is not necessary to add expander to early production units which did not originally have it.

DESCRIPTION: Self-contained, combined vacuum and hydraulic unit using intake manifold vacuum and atmospheric pressure for its pressure. In "brake-released" position power piston is balanced by atmospheric pressure on both sides of piston. Unit incorporates two main sections—vacuum power cylinder and hydraulic master cylinder. Unit replaces conventional master cylinder only. *NOTE*—On Buick master cylinder fluid reservoir is separate.

OPERATION: With engine running, brake unapplied, both sides of power piston are under atmospheric pressure. On application of brake pedal, intake manifold port opens and creates vacuum right side of power piston. Atmospheric pressure then moves power piston to right thereby exerting thrust on hydraulic plunger. This increases line pressure to four wheels. Release of brake pedal restores atmospheric pressure balance in power cylinder. In case of engine failure and consequent loss of engine vacuum, several applications of brake are possible by using vacuum supply in vacuum reservoir. In case of complete vacuum loss, brakes can be applied in conventional manner, although more effort is required due to loss of power assist.

POWER BRAKE ASSEMBLY

CHECKING & ADJUSTMENT: Check all parts of power brake system before disassembling Power Brake Unit whenever brake trouble experienced.

Adjustments: No special adjustments required. Anytime brake pedal goes to within 1". from floor (floor mat to underside of pedal pad), brakes should be adjusted. At time brakes adjusted, following inspections must be made:

1) Check vacuum lines and connections between intake manifold, check valve, vacuum reserve tank, and vacuum power cylinder for possible vacuum leaks.
2) Check fluid level in master cylinder reservoir. See Lubrication below.
3) Check condition of air cleaner element and insert clean element, if necessary.
4) Check steering column pedal plate for loose screws. Check for free operation of brake pedal. If binding exists, check for misalignment between pedal and vacuum cylinder pushrod.
5) Check stop light switch for proper operation.

Bleeding Brakes: Bleed in same manner as for standard brakes. Do not use vacuum assist while bleeding. Engine should not be running and vacuum reserve should be reduced to zero by applying brake several times before starting bleeding procedure. After power unit reinstalled, bleeding of power unit and flex line can be accomplished at junction block bleeder screw, provided remainder of system is free of air.

LUBRICATION: Check level of brake fluid in reservoir every 1000 miles. Refill to ½-1" from top of filler plug opening (Buick), high enough to register on dipstick (Oldsmobile), ½" from top of filler plug opening (Pontiac). *NOTE*—Reservoir is separate and under hood on Buick.

PERIODIC SERVICE: Intake manifold tee connector should be removed and cleaned Spring and Fall or every 10,000 miles.

TROUBLE SHOOTING: Before checking Power Brake Unit for source of trouble check remainder of brake system.

Hard Pedal: 1) Vacuum failure due to faulty vacuum check valve, collapsed vacuum hose, plugged vacuum fittings, hose or pipes, leak between vacuum power cylinder and hydraulic master cylinder.
2) Bound up pedal mechanism.
3) Power Brake unit trouble—internal vacuum hose loose or restricted; jammed sliding valve; vacuum leaks in unit caused by loose piston plate screws, loose piston packing, faulty master cylinder piston, vacuum seal, or leak between hydraulic master cylinder and vacuum power cylinder; defective diaphragm; restricted air cleaner.

Grabbing Brakes (Apparent Off-and-On Condition): Power Brake unit valve trouble—reaction diaphragm leakage, faulty rubber bumper pad in reaction diaphragm; sticking sliding valve reaction; restricted diaphragm passage; master cylinder piston binding in power piston guide.

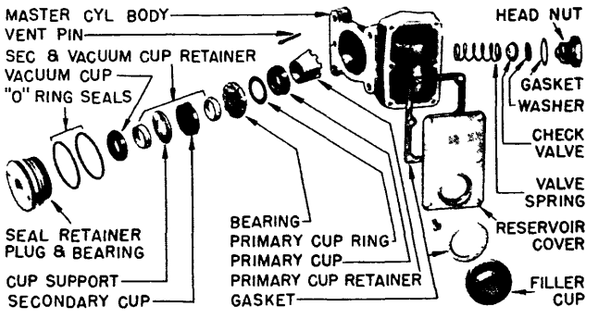
P dal Goes to Floor (Or Almost to Floor): Brake adjustment; fluid reservoir needs replenishing, power brake hydraulic leakage—defective primary or secondary cup, defective vacuum seal, defective head nut or head

CONTINUED ON NEXT PAGE

MORAINE POWER UNIT (Cont.)

nut gasket, cracked master cylinder casting, leaks at wheel cylinders or in pipes, or in connections, defective "O" rings on cylinder plug.

Brakes Fail to Release (Or Slow Release): 1) Bound up brake pedal linkage.



2) Weak brake shoe return springs, or rusty bosses on backing plate.

3) Faulty residual check valve, excessive hydraulic plunger seal friction, excessive piston packing friction, restricted air passage in vacuum piston, restricted air cleaner, sticky air valve, broken piston return spring, broken air valve return spring.

REMOVAL & INSTALLATION: Buick–Remove starter splash plan. Disconnect return spring, loosen locknut on cylinder pushrod, remove clevis pin at brake pedal, then unscrew pedal pushrod from cylinder pushrod. Disconnect air inlet hose at air filter on brake cylinder, and disconnect hoses from vacuum tee on opposite side of cylinder. Disconnect reservoir-to-hydraulic cylinder pipe, allow reservoir and pipe to drain. Disconnect distributor-to-cylinder pipe and allow to drain. **Discard old fluid** and cover pipe with tape to exclude dirt. Remove nuts and lockwashers attaching power cylinder to its support and remove cylinder from car. Install power cylinder by reversing removal procedure. Adjust pushrods by screwing cylinder pushrod in or out of pedal pushrod until pedal grommet is compressed to approximately ¾" after it contacts toeboard with pedal in released position.

Oldsmobile: Disconnect hydraulic line at power brake master cylinder (*NOTE*–Use care to prevent dirt entering hydraulic line and secure hose so open end is above level of junction assembly to prevent loss of fluid. Plug master cylinder outlet with rubber stopper). Disconnect stop light leads and fold back floor mat. Remove brake pedal bracket attaching bolts, then remove bracket and pedal assembly. Remove mast jacket grommet retainer and slide grommet up mast jacket. Remove mast jacket cover plate attaching screws. Loosen speedometer cable hold-down clip and slip cable from under clip, remove speedometer cable and grommet from mast jacket cover plate. Remove two cover plate-to-power cylinder bolts, and remove cover plate while positioning power brake unit so it rests on edge of opening in toe pan. Disconnect vacuum hoses and remove power brake unit through toe pan opening. To install, reverse removal procedures.

Pontiac: Disconnect vacuum hose from vacuum pipe running from vacuum tee connector, disconnect hydraulic pipe from outlet fitting on hydraulic cylinder. Disconnect pushrod from pedal and wires from stop light switch. Remove nuts from U-bolt retaining pedal pivot bracket (with stop light switch assembly attached). Remove clutch pedal seal retainer (Synchro-mesh cars) and steering column seal retainer, remove seals. On Hydra-Matic cars, remove screws in mounting plate, remove plate with power brake unit attached. On Synchro-mesh cars, remove screws which retain power brake unit to mounting plate (brake unit will rest on frame). Remove screws which retain mounting plate to floor pan and remove mounting plate "jockeying" as necessary to clear clutch pedal. Remove power brake

MASTER CYLINDER UNIT

unit (*CAUTION*–Do not support or carry brake unit by pushrod since pushrod may be pulled out of plunger). Remove mounting plate from brake unit, if not previously removed, and remove vacuum hose from vacuum cylinder inlet tube. To reinstall, reverse removal procedure (*NOTE*–Brake pedal pivot bracket has tang which mush fit in a hole in steering column). Fill reservoir, bleed system, test brakes. *NOTE*–In installed position there should be approximately 1/8" clearance between pushrod and bore of plunger.

OVERHAUL: *CAUTION: Use extreme care in the handling of hydraulic system parts to prevent their coming in contact with mineral oil or grease. DO NOT HANDLE HYDRAULIC PISTON CUPS OR SEALS WITH GREASY HANDS.*

Disassembly (Oldsmobile & Pontiac): Clean all dirt from outside of power brake unit Remove dipstick and gasket (Oldsmobile), filler cap and gasket (Pontiac), from master cylinder and pour brake fluid out of reservoir (*NOTE*–Operate pushrod by hand with unit upside down to pump fluid from cylinder bore). Clamp master cylinder end of unit in holding fixture J-5433 with adapter J-5796 and remove cable guide. Remove screw that holds air cleaner unit to outside of power cylinder. (*CAUTION*–Removal of air cleaner unit must precede disassembly of internal parts to avoid damage to large leather piston cup inside power cylinder housing). Remove boot and felt silencer from pushrod end of brake unit Remove end cover and gasket (held to power cylinder housing by two recessed flat head screws) Slip rubber exhaust hose from vacuum exhaust tube inside power cylinder housing (*NOTE*–Do not use compressed air to remove). Press power cylinder assembly back into power cylinder housing so that it does not rub against vacuum exhaust tube. Holding power piston in this position with one hand, remove two screws that hold vacuum exhaust tube to outside of power cylinder. Using fine emery cloth remove burrs from inside power cylinder housing at screw holes. Ease power piston out of power cylinder housing (There is a strong coil spring back of power piston assembly. Be careful to control piston by hand as it is removed from housing) Remove large coil spring from inside power cylinder housing. Remove hex head bolts at the inside base of power cylinder housing that hold it to master cylinder (*NOTE*–Power cylinder housing pilots on an extension of cylinder plug and should be removed carefully so as not to damage "O" ring on plug extension).

Air Cleaner Unit–Pull screw out through housing and assembled parts. Unseat rubber gasket from edges of housing, lift out element and hairpin spring.

Master Cylinder–Clamp master cylinder in fixture J-5433 with adapter J-5796 or in a vise in vertical position and remove cylinder plug assembly using special spanner wrench J-5794. Remove two "O" rings from outside diameter of plug. Remove secondary cup and washer from inside of plug. Inspect vacuum seal assembly in plug. If seal appears to be in good condition and there has been no indication of a vacuum leak, DO NOT attempt to remove vacuum seal assembly from cylinder plug. If vacuum seal defective, cylinder plug and vacuum seal must be replaced as an assembly. **On Oldsmobile,** from the bore of the master cylinder, lift out spacer, plunger bearing, primary cup washer, primary cup and retainer. **On Pontiac,** from the bore of the master cylinder, lift out expander, spacer, bearing, flat primary cup ring, primary cup and conical retainer. Reset master cylinder in vise or Tool J-5433 and remove head nut assembly and copper gasket (*NOTE*–Be careful so that check valve and check valve spring do not fall from hole as head nut is loosened). Remove rubber check valve seat washer which fits over button on head nut. Lift out check valve and check valve spring. **On Oldsmobile,** remove cover assembly. Note position of filler tube in relation to master cylinder body so that it may be installed in same position on reassembly. **On Pontiac,** inspect fluid reservoir through filler hole opening. If reservoir is dirty to the extent that it cannot be cleaned thoroughly through filler hole, remove reservoir cover and gasket. Make note of position of filler hole in relation to master cylinder body so that it may be installed in same position on reassembly. **On Oldsmobile and Pontiac,** inspect vent on underside of casting. (Vent pin is designed to keep this hold open). If hole clogged and cannot be cleaned out so that pin rides free, pin may be straightened and removed through counterbore end of vent hole.

Power Piston Assembly–Remove vacuum hose from power piston assembly if it is to be replaced (*NOTE*–Hose is cemented to tube). Carefully unseat triangular shaped lock ring with screw driver to permit removal of pushrod and air valve assembly. Use caution in removing lock ring so that it will not flip out and become lost or cause personal injury. Turn power piston assembly upside down. Stop plate washer will slide out of opening in power piston and down onto pushrod. Carefully pull out air valve and pushrod while holding piston in vertical position. Valve spring and shims will come out with air valve (*CAUTION*–Lift out spring and make note of number of shims which fit over valve shank and rest on valve shoulder). Remove "O" ring from air valve. (*NOTE*–It is not necessary to remove pushrod from air valve unless it is noisy or excessively loose). If necessary unseat snap ring by pinching snap ring with pliers J-5403. Pull out pushrod, remove rubber bumper from end of pushrod (ring and washer may be left on pushrod). Set power piston assembly on bench on hub end and loosen four screws that hold two halves of power piston assembly together. Before

CONTINUED ON NEXT PAGE

MORAINE POWER UNIT (Cont.)

completely removing screws press down on top half (power piston guide) with one hand. *(NOTE*–There is an internal spring between two halves that will have a tendency to part the two halves unless controlled by hand). Gently lift off power piston guide and master cylinder piston assembly. Turn upside down and remove "O" ring from pilot on power piston guide. Slide power piston guide off master cylinder plunger and remove "O" ring from master cylinder plunger. Examine reaction plate, which is held to end of master cylinder piston by small Truarc ring. If necessary to remove remove reaction plate, expand Truarc ring with special pliers J-4880 and lift off reaction plate. From counterbore of power piston, remove in order six fingers (or reaction levers), reaction spring, valve plate, and valve diaphragm spring. Carefully lift large leather cup off power piston. Keep in mind that underneath leather cup is a metal lip expander and wick assembly that has a tendency to uncoil when released. Wick and expander may be separated for inspection. Eject floating valve assembly from power piston by pulling out or by thumb press from hub end. If parts stick together and cannot be pressed out with fingers, pry gently from opposite end to loosen. Remove rubber power piston stop bumper from hub of power piston.

Floating Valve Assembly–Unseat cup-shaped valve spring retainer with small screw driver *(CAUTION*–Use care to prevent screw driver from damaging diaphragm). Press floating control valve through inner diameter of diaphragm. This also frees diaphragm retainer plate. Unseat rubber diaphragm from groove in diaphragm retainer ring.

Disassembly (Buick): Mount power brake cylinder in vise with hydraulic cylinder down, being careful not to damage the loose vent pin in flange of cylinder. Tighten vise only enough to hold cylinder firmly *(CAUTION*–Excessive tightening will distort or crack cylinder). Remove pushrod boot and retainer from housing cover. *Do not attempt to remove pushrod which is anchored in air valve by a spring type lock.* Remove housing cover bolts, cover, and gasket. While holding power piston down, disconnect vacuum hose from vacuum tee and gasket from housing. *Slowly* release power piston to control the pressure of piston return springs as piston and attached parts emerge from housing. Make sure that lip of leather piston cup does not catch in holes in housing. Remove power piston from air valve, then place valve and hydraulic piston assembly where polished surfaces of valve and piston will not be damaged by contact with other parts.

Air Cleaner Unit–Remove screw from air cleaner cover and assembled parts. Remove gasket, filter core, and spring from the cover.

Power Piston Assembly–Remove eight screws with lockwashers, piston guide, piston cup (leather), and the felt lubricating wick with expander spring from power piston. Remove rubber stop bumper but leave "O" ring inside piston hub and vacuum hose for later inspection.

Valve & Hydraulic Piston Assembly–Support valve and hydraulic piston assembly in an 8" length of 3" pipe, or its equivalent, with pushrod up. Remove snap ring, then lift air valve with attached control valve out of pivot plate and remove reaction spring. Remove lock ring, using ring pliers J-4880. Remove valve reaction plate, valve diaphragm spring, and control valve and diaphragm assembly from air valve. *(NOTE*–One to four spacers (washers) may be on the middle shoulder of air valve, but some assemblies require none. Note the number of any spacers present, then remove spacers from air valve). Remove diaphragm retainer from valve diaphragm, carefully pry off valve spring retainer, then remove diaphragm and retainer plate from control valve. Remove air valve return spring from bore of hydraulic piston. Remove snap ring, lift piston with cover out of pivot plate, and remove reaction levers. Remove snap ring, reaction plate, and cover from piston. Remove piston return springs from cylinder housing. Remove four nuts and lift housing from hydraulic cylinder. Remove gasket. Unscrew and remove cylinder plug from hydraulic cylinder body, using Spanner Wrench J-5794, then remove secondary cup, cup support retainer, and vacuum cup seal. Remove cup retainer, piston bearing, cup ring, primary cup, and primary cup retainer from cylinder body. Remove head nut with gasket, and check valve and spring from cylinder body.

Push Rod-Air Valve Assembly–*(CAUTION–Do not attempt to remove pushrod from air valve unless one part is damaged so that replacement is required).* To unlock pushrod, prepare a piece of 3/16" steel rod about 7" long by filing flats on one end to reduce size to 5/32", then use as a punch to bend both arms of pushrod lock. Grip hex of pushrod in vise and pull on air valve to separate these parts, then insert thin metal strips through air holes in valve to remove the lock. *Use care to avoid damaging annular seat on air valve.*

Cleaning & Inspection: Clean all parts in diacetone alcohol or clean brake fluid *(CAUTION–Do not use antifreeze alcohol, gasoline, kerosene, or any other cleaning fluid that might contain even a trace of mineral oil, as this could cause serious damage to all rubber parts in brake system).* Blow parts dry with air. As an aid in determining cause of power brake failure, carefully examine all rubber parts for nicks, cuts or other damage. After examination, discard these rubber parts if Overhaul Kit being used for repair. Blow dirt and cleaning fluid out of all internal passages. Make sure that small compensating ports in end of master cylinder plunger (hydraulic piston on Buick) are clear. If plugged, clean thoroughly and flush hydraulic system to remove all dirt. Outer surface of master cylinder plunger (hydraulic piston), bore of master cylinder (hydraulic cylinder on Buick) or vacuum cylinder, may be cleaned or reconditioned with fine crocus cloth if not too deeply pitted or scratched. If any parts indicate that heavy abrasive action has resulted from severe contamination of brake fluid, replace damaged parts and be sure to flush fluid reservoir and wheel cylinder lines thoroughly. Make sure that vent pin is properly retained in hole and that vent hole is clear. If using Overhaul Kit for repair of power brake use all new parts in kit regardless of whether old parts appear fit for use. The six reaction levers may be flattened with a wooden mallet if they are not badly distorted.

Reassembly (Oldsmobile & Pontiac): *CAUTION–During reassembly make certain that no grease or mineral oil comes in contact with internal parts of unit. Until used, keep cleaned parts on clean paper or cloth.* Master Cylinder–1) Drop check valve spring into place in 1" threaded opening in master cylinder casting. Seat check valve assembly into check valve spring. Button check valve seat washer onto head nut, and fit copper head nut gasket over threaded end of head nut. Screw head nut in place carefully to avoid binding check valve as it is depressed into hole in casting. A few drops of brake fluid on check valve seat washer will facilitate assembly. Torque to 80-90 ft. lbs. (Oldsmobile), 85-100 ft. lbs. (Pontiac).

2) Replace reservoir gasket and cover. Install all screws with exception of cable guide attaching screw (Pontiac). Be sure cover is installed with filler hole (Pontiac), filler tube (Oldsmobile), in proper position. Install filler cap and gasket loosely (Pontiac), or dipstick (Oldsmobile) to avoid danger of dirt entering reservoir during reassembly of unit.

3) Clamp master cylinder in fixture or vise, in vertical position, with large counterbore facing upward. Wipe counterbore and threads with very thin coating of brake fluid. Place conical primary cup retainer with notched end down into open end of bore. Press primary cup into hole (Note that outer lip of primary cup fits around and over small end of retainer when it is properly centered in hole). Place primary cup retainer (thin blued steel washer) in place on back of primary cup. Set bearing into bore with notched side up, making sure that hub of bearing fits into counterbore on back of primary cup. Place spacer on top of bearing. On Pontiac, place expander on top of spacer with fingers toward bearing. *(PONTIAC NOTE*–Early production units did not have an expander. If an expander is to be installed on these units a new spacer, with a 1/32" larger diameter, will be required. For a short time a a spring loaded expander was used in place of expander and spacer. In this case place spring on bearing and expander on spring).

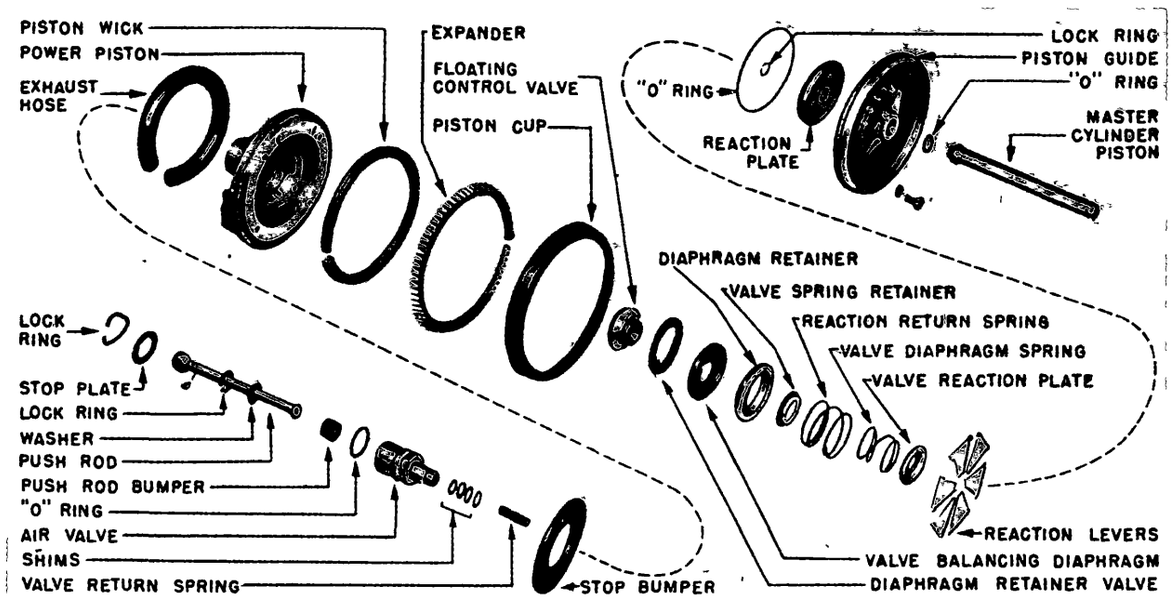
4) Assemble cylinder plug assembly as follows: Seat vacuum cup seal with ribbed sides up into bottom of counterbore cylinder plug. Place spacer on top of vacuum cup (this spacer is smaller in diameter than secondary cup spacer), follow with secondary cup washer. Seat secondary cup with ribbed side up in large counterbore. Slip 1 51/64" "O" ring into first groove on outside diameter (nearest end of plug opposite threaded section), slip second 1 51/64" "O" ring over threaded end and seat on hub which has same diameter as first groove. *CAUTION*–No "O" ring should be placed in second groove that has four small through holes.

5) Screw cylinder plug assembly into place *(CAUTION*–On Oldsmobile, spacer must be properly centered on top of bearing, then carefully install plug assembly so that lip of secondary cup fits around spacer when plug is screwed into place. On Pontiac, spacer and expander must be centered properly on bearing so that lip of secondary cup fits around expander when plug is screwed into place). Use special Spanner Wrench J-5794 for tightening cylinder plug assembly (20-30 ft. lbs.).

CONTINUED ON NEXT PAGE

MORAINE POWER UNIT (C nt.)

6) If necessary, replace vent pin in vent hole and bend to approximately 45° to hold in place. Head of pin rides in counterbore of hole.



7) Assemble power cylinder housing to master cylinder with four 5/16" hex head screw and lockwasher assemblies (12-14 ft. lbs.). Be sure to install gasket between housing and master cylinder and position notch in gasket over vent hole in cylinder. The housing pilots on the extended portion of cylinder plug assembly. Assembly is facilitated by wiping bore of housing pilot hole with thin coat of brake or Hydra-Matic fluid. In assembling the housing be sure that two 3/8" air intake holes are on top (match reservoir cover side of master cylinder). Exercise care in installing housing so that "O" ring on cylinder plug extension is not damaged.

Floating Valve Assembly–Fit rubber diaphragm over small diameter of diaphragm retainer ring. Hold diaphragm retainer plate on back of diaphragm with one hand, flat side of plate adjacent to rubber; press floating control valve into place over retainer plate. The hub end of valve fits through the hole in the rubber diaphragm. Press cup shaped valve spring retainer over hub of floating valve and inner flange of diaphragm. Wipe outside diameter of floating valve with Hydra-Matic fluid or Dow Corning No. 4 Silicone Grease.

Power Piston–Set power piston casting on bench, hub end down. Press by hand the floating valve assembly, with rubber valve face down, into power piston counterbore. Assemble felt wick in channel of metal lip expander. *(NOTE*–If new wick is used, soak in Hydra-Matic or Shock Absorber fluid, allowing excess to run off). Install wick and expander assembly into outer groove of piston with expander fingers on outside and pointing toward hub end of power piston. Holding expander in place, slip rubber cup in place with lip also pointing toward hub end of piston. If new leather cup is installed use cardboard cylindrical retainer to confine cup during installation. This will avoid any sluggishness in operation during first few days of use or until leather becomes softened by fluid. Snap valve diaphragm spring in place over valve spring retainer. Seat valve plate on top of valve diaphragm spring so that center portion nests in spring. Place reaction spring around valve diaphragm spring and seat in recess of valve diaphragm retainer. Set six reaction levers in place. Ears on levers fit into mating slots in face of power piston. Small ends of levers will extend toward middle and rest of reaction spring.

Piston Guide–Place 5/8" "O" ring in groove of master cylinder plunger. Place reaction plate over small end of piston with raised edge extending outward. Retain reaction plate on plunger with Truarc snap ring using pliers J-4880. Lubricate lightly "O" ring and adjacent surface of master cylinder plunger with Dow Corning Valve Seal "A" or equivalent silicone grease. Fit 3½" "O" ring onto machined hub of piston guide.

Power Piston & Piston Guide–Holding master cylinder plunger assembly in one hand, in vertical position with reaction plate down start piston guide (ribbed side up) over upper end of plunger. Gently seat master cylinder plunger and reaction plate assembly onto reaction levers. Press down quickly and firmly until the six reaction levers are held in flat position. Be sure each lever is properly seated. Place hand on top of master cylinder plunger to hold in place. Gently slide piston guide into place indexing holes to match those in piston casting. Install four hex head ¼"screws and lockwashers to complete assembly (5-7 ft. lbs.) To assure that reaction levers are properly seated, check to see that master cylinder piston has slight movement in power piston assembly. Turn the assembled unit over and install rubber bumper in groove on hub of power piston.

VACUUM POWER PISTON UNIT

Air Valve & Pushrod–1) Assemble rubber bumper onto end of pushrod. Insert bumper and pushrod assembly into air valve. Allow metal washer on pushrod to seat on back of rubber pushrod bumper. Using special pliers J-5403, snap Truarc ring into groove in air valve. Check carefully to make sure that pushrod is firmly locked into air valve. Assemble 1" "O" ring in narrow groove on outside of air valve. Coat "O" ring and outside diameter of air valve with light coat of Dow Corning valve Seal "A" or equivalent silicone grease.

2) Place same number shims that were on air valve, on Tool J-5805. Invert power piston and insert gauge into bore of power piston. Shims and body of gauge will rest on valve plate and pin will extend through hole in valve and rest on end of master cylinder plunger. Turn power piston over so that gauge is on top and check position of pin in gauge body. Pin should be flush or slightly above gauge body. If pin is flush or less than .010" above body, no further adjusting is required. If pin is below top of gauge body, remove shims one at a time until pin is flush or not more than .010" above top of gauge body. If pin is more than .010" above top of gauge body, disassemble and inspect for bent reaction levers, reaction plate or valve plate. After proper number of shims have been added to small diameter of air valve, insert valve return spring hole in air valve.

3) Holding power piston and guide assembly with master cylinder plunger pointing upward, insert from below the air valve, spring, and pushrod assembly into hub end of power piston. *CAUTION*–Assemble in this manner to avoid dislodging shims and valve return spring.

4) Carefully turn power piston, guide, air valve and pushrod assembly over and insert stop plate and triangular lock ring which holds air valve in place. Lock ring may be assembled by using small screw driver. After being locked in place, the air valve will have approximately 1/32" travel against valve return spring before picking up floating valve load. *CAUTION*–Care should be exercised during this operation to avoid damage to master cylinder plunger. Never put master cylinder plunger in a vise.

Power Piston & Guide Assembly in Power Cylinder Housing–1) Lubricate lightly the large bore of power cylinder housing with Hydra-Matic or Shock Absorber fluid. Clamp the master cylinder in vise or Tool J-5433, in a vertical position with opening in housing extending upward. Place large coil return spring into housing with large diameter in bottom of housing. The tang on bottom of spring should be placed in narrow space between any one of hex bolt heads and closest locating dimple.

CONTINUED ON NEXT PAGE

MORAINE POWER UNIT (C nt.)

2) Wipe lip of leather cup with light coating of Hydra-Matic or Shock Absorber fluid to clean and lubricate. If rubber exhaust hose has been removed from power piston for replacement, coat exhaust tube with 3M Super Weatherstrip Cement and slip new hose on tube as far as it will go.

3) Place power piston and assembled parts on top of coil spring so that the boss plugged with the largest ball will enter housing below the exhaust tube hole in housing by approximately ¼". Press power piston assembly into housing. Depress power piston assembly into housing against coil spring load. This permits assembly of exhaust tube and gasket to outside of housing. Install tube in proper direction so that inside connection will assemble correctly with rubber exhaust hose (Two filister head screws). Slip rubber exhaust hose onto metal exhaust tube inside housing (approximately 1/2-5/8"). Permit power piston to ease back against exhaust tube connection. Install power cylinder cover and gasket using two flat head screws. Press cover down by hand in order to start screws into housing. Slip felt silencer and boot over p ushrod. Seat felt silencer against hub of power piston and fit boot snugly over flange on housing cover.

Air Clean r–Lay hairpin spring inside air cleaner cover. Lay filter element on top of hairpin spring. Place rubber gasket on filter element, depress spring and element so that edges of gasket can be fitted over flanges of air cleaner housing. Insert cover screw with gasket in place through assembled unit and screw into top housing. *CAUTION*–Air cleaner assembly must not be assembled to housing prior to this time, otherwise there is danger of damaging leather piston cup, because air cleaner cover screw extends through inside of housing.

R ass mbly (Buick): *CAUTION–During reassembly make certain that no grease or mineral oil comes in contact with internal parts of unit. Until used, keep cleaned parts on cle an paper or cloth.*

Valv & Hydraulic Piston Assembly–1) Mount hydraulic cylinder body in vise with flanged end up. Install new valve seat washer and new gasket on head nut. Place spring and new check valve (concave side outward) in cylinder body, then install head nut and tighten securely.

2) Place primary cup retainer in cylinder body with notched end inward. Dip new primary cup in clean brake fluid and install with flat side outward, using care that cup lip is not turned back at any point. Center the primary cup ring on cup and install piston bearing with notched face forward, pressing bearing down against shoulder in body. Dip new vacuum seal and secondary cup in clean brake fluid. Install seal in cylinder plug with flat side inward, center seal retainer in seal, then install cup support against shoulder in plug. Install secondary cup with flat side inward against the support. Place new "O" ring in the two outer grooves of plug and lightly coat them with silicone grease. Center secondary cup retainer on piston bearing and screw cylinder plug down into cylinder body, using care not to damage "O" ring or secondary cup. Tighten plug firmly, using Spanner Wrench J-5794.

3) With housing gasket placed on hydraulic cylinder so that one notch is at vent hole, install cylinder housing with two large holes for air cleaner on same side as head nut. Install four nuts and tighten securely.

4) Install new "O" rings on hydraulic piston and the reaction cover, lubricating both "O" rings and the bore of cover with silicone grease. Install piston reaction plate with **concave side of rim** toward shoulder of piston and install lock ring. Slide cover over piston with concave side toward reaction plate, using care to avoid damaging "O" rings.

5) Place six reaction levers in their slots in pivot plate. Install hydraulic piston and cover assembly in pivot plate and install snap ring. Install new rubber seal in groove in small end of pivot plate and lightly coat seal with silicone grease.

6) Check for number of spacers that may be required for proper location of valve reaction plate as follows: Support pivot plate in 3" pipe with hydraulic piston downward so that piston reaction plate rests against cover and all levers rest on plate. Center valve reaction plate on reaction levers with rounded side of rim against levers. Install Spacer Gauge J-5805 on reaction plate so that long end of plunger extends through to rest on upper end of hydraulic piston, then note whether upper ends of gauge plunger and sleeve are at same level. Any slight difference may be felt with a finger. If necessary install one or more spacers around plunger and between sleeve and reaction plate until plunger and sleeve are level. If exact level cannot be obtained, select the number of spacers that places plunger slightly **above** rather than below end of sleeve. Make note of number of spacers to be used for later installation.

7) Place **flat** side of retainer plate against **flat** side of valve diaphragm, push hub of floating control valve through plate and diaphragm, fitting flange of diaphragm into groove in valve, then press spring retainer over hub of valve. Slip outer flange of diaphragm over the smaller side of diaphragm retainer.

8) Place spacers selected in step **6)** on shoulder of air valve and install floating control valve and diaphragm assembly with rubber valve seat against seat on air valve. Place valve diaphragm spring over spring retainer, install valve reaction plate with **concave side of rim** against the spring, then depress these parts and install lock ring.

9) Place air valve return spring in bore of hydraulic piston and center the reaction spring on the reaction levers. Lubricate small stem of air valve and rim of rubber diaphragm with silicone grease, install air valve with control valve in pivot plate and install snap ring.

P w r Pist n–Coat vacuum hose tube of power piston with 3M Super Weatherstrip Adhesive, then push one end of vacuum hose all the way up on tube, turning hose so that it is flat against piston. Install rubber stop bumper in groove of piston hub. Place felt lubricating wick in the expander spring, saturate with Dynaflow fluid, then install in groove of power piston with spring fingers outward and pointing toward bumper end of piston. With rubber piston cup retained in the cardboard ring in which it was shipped, install cup over expander spring, making sure it is centered, then install piston guide and attaching screws with lockwashers. NOTE–Use of cardboard ring will confine cup during installation and avoid sluggishness during first few days of operation or until leather becomes softened by fluid.

Power Piston & Guide Assembly in Power Cylinder Housing–1) Install new "O" ring in largest groove inside hub of power piston, coat it with silicone grease and fill two outer grooves with this grease. Lightly coat rubber seat of control valve with same grease, then slide piston into place over air valve, using care to avoid damaging "O" ring.

2) Apply an even coating of Dynaflow oil to inside of cylinder housing, **being careful to keep this oil out of hydraulic cylinder.** Coat surface of the power piston leather cup with same oil.

3) Center small piston return spring in cylinder housing, then place large return spring around it with smaller end downward, locating the bent end of spring wire between one of bolt heads and adjacent dimple pressed in cylinder housing.

4) Wipe off hydraulic piston with a clean cloth to remove any oil or grease and apply a film of clean brake fluid to surface of this piston **only.** Remove cardboard retainer ring and place power piston and attached parts on large return spring so that bent end of spring wire rests between two of the round bosses on piston guide. Locate piston so that when it is pressed into housing the side of boss oppos te t!.e vacuum hose clears the vacuum tee hole in housing by approximately ¾". Push power piston down into cylinder housing, entering hydraulic piston into hydraulic cylinder, and hold piston down while installing vacuum tee with gasket and two screws. Push end of vacuum hose up on tee about 5/8".

5) Push power piston down and allow springs to return it several times to check for free operation and proper position on springs, then install gasket and cover on cylinder housing with four bolts, lockwashers, and nuts tightened securely.

Air Cleaner Unit–Place hairpin spring and filter core in air cleaner cover, snap the rubber gasket over flanged edge of cover, and install this assembly on housing with screw and gasket. The tube must point toward the air valve.

Pushrod–Air Valve Assembly–If pushrod was removed from air valve, place a new lock over ball end of pushrod and press parts into air valve until both ends of lock snap into place behind shoulder inside air valve. Install pushrod boot so that it fits in groove on rod and over flange on housing cover. Wrap retainer around boot where it fits over cover and lock in place.

►CHANGES, CAUTIONS, CORRECTIONS

►*1951 CADILLAC 61, 62, & 60S SELF-ADJUSTING ANCHOR NOTE* Shoes are automatically centered within drums to compensate for wear on linings *See Minor and Major Adjustments below*

►*1952 BUICK 70 FRONT BRAKE SHOE PRODUCTION CHANGE & REPLACEMENT PARTS CAUTION* 1953 design FRONT brake shoes used on late 1952 cars beginning Serial No 16668190 (approx Sept 12 1952) These shoes have different geometry and are identified by heavier, more rounded corners at anchor pin and heavy boss or roll on edge of rib at adjusting screw end so that adjusting nut does not touch rib *ONLY NEW STYLE BRAKE SHOES FURNISHED FOR SERVICE AND NEW OFFSET ANCHOR PIN MUST BE USED WHEN THESE SHOES INSTALLED ON EARLIER CARS*

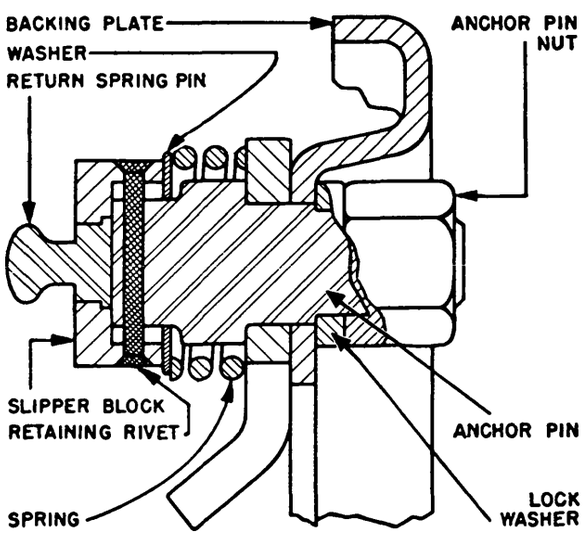
1952 Series 70 Brake Shoe & Lining Sets

	Std Size*	030" Oversize
Front	1391154 ©	② 1391153
Rear	1390830	1390831

©—Supersedes No 1390942
②—Supersedes No 1390941

►*CAUTION—When using above FRONT shoe assemblies to replace first type on early 1952 cars, install NEW OFFSET TYPE Anchor Pin No 1161604 (necessary to provide proper positioning of shoes)*

►*1950-54 PONTIAC BRAKE SILENCER SPRINGS (To Correct Brake "Squeak")* Brake Drum Silencer Spring Pkg No 514278 is available to correct above complaint To install make up four tools (see below) and install tools on four of the five wheel studs (use wheel nuts to hold tools in place) place spring on drum over the four tools roll spring on drum flange using large screwdriver to pry spring on drum at point between two wide spaced installing tools Install three clips approximately 120° apart to retain spring on drum Remove tools and re-install wheel



INSTALLATION TOOL NOTE—Make up tool from 1" wide strap iron with 17/32" hole centered on strap ¾" from one end (to engage wheel stud) Bend opposite end over in form of "U" 3¾" from center of hole and ¾" deep (return on end should be ½" long so as to fit over rim of brake drum)

►*1954 CADILLAC BRAKE PEDAL FREE TRAVEL CAUTION* The upper half of brake pedal for the standard brake is not the same as the one for power brakes Should the incorrect upper half be installed for the standard brake the **free travel** will not be correct, and full brake action cannot be obtained. The correct measurement (from carpet to lower edge of brake pedal plate) for standard brake is 5¾" (Power Brake 4 7/8"). NOTE—To obtain full brake pedal travel, the rubber grommet should rest against the bottom of toe-board when brake is fully released.

►*1953 CADILLAC BRAKE LINING MATERIAL AND DESIGN CHANGE* Late 1953 and 1954 cars are equipped with new material brake linings. New material, plus shorter linings on primary shoes, plus a ½" groove down the center from end to end of primary shoes, gives softer more positive pedal action, and better heat dissipation, with longer brake lining life

►*1954 OLDSMOBILE BRAKE RETRACTING SPRING CAUTION* Spring load specifications are important to obtain long life from linings. Spring load should be 45-55 lbs. when spring stretched to its normal length (4 7/8"). Free length should be 4½". Measure the distance from end of long hook to inside edge of other hook at opposite end. Replace spring when free length over 4½" or load not within specifications.

►*1955 BUICK 40 & 60 SERIES LONG BRAKE CABLE CORRECTION (Early Cars)* To correct, disconnect rear brake cable by removing nut and cable sheave Cut a piece of ¼ steel pipe or tubing that will slip closely over front cable rear shank to length necessary to get ample adjustment One inch length should be adequate Install this spacer on shank between rear cable sheave and adjusting nut Adjust cable to proper tension and lock adjusting nut by installing a plain 5/16 nut as a jam nut and tightening securely against adjusting nut Check with parking brake in fully applied position to be sure cable sheave does not come up to rubber grommet There should be at least ½ clearance If cable sheave within ½ of grommet in fully applied position, remove hand brake cable support (rubber covered bracket) and weld a new one, Part No 1311223, one or two inches farther ahead on torque tube Steel shank of front cable must ride in the grommet

CADILLAC 1951 "SELF-ADJUSTING" ANCHOR

►*BUICK UNEQUAL, ERRATIC, OR SQUEAKING BRAKE CORRECTION* To correct, proceed as follows **(1)** Air tires to 24 pounds Expand brake to a two hand drag in a forward direction (**Do not** tighten excessively so as to distort drum) **Do n t** attempt to expand brake by having another mechanic apply pressure to brake pedal **(2)** Make Anchor Pin Adjustment (See Adjustments below), and repeat adjustment until amount of drag remains constant **(3)** Make Major Brake Adjustment (See Adjustments below) **(4)** Repeat **(2)** and **(3)** above on all remaining wheels If any brake has noticeably more drag than others after releasing adjustment 6 notches, repeat anchor pin adjustment on that brake If still not comparable with others, remove wheel and check brake assembly and backing plate for cause of binding and correction condition If, during adjustments, anchor pins on one or more brakes were moved, car should be road tested Usually, during first few applications, original condition will return and then will gradually improve until, after 15 to 20 applications, brakes will begin to operate normally

►*1954 & EARLY 1955 CADILLAC EXCESSIVE PEDAL EFFORT CORRECTION* When checking for cause of excessive pedal effort on 1954 Series cars and 1955 Series Cars built prior to Engine No 22750, examine brake pedal position on shaft If pedal has moved out over lock ring to such an extent that it is binding, replace shaft and lock ring, using new shaft Part No 3510310, and new lock ring, Part No 1463434 New part numbers are applicable to 1950 through 1955 Series cars equipped with Hydra-Matic transmissions

►*1955 CADILLAC BRAKE PEDAL BINDING CORRECTION (Cars Built Prior To Engine No 12725)* To correct bind at clevis and bell crank linkage of brake pedal assembly, install a 1/8' flat washer between frame and master cylinder attaching bosses After installing washer, check linkage throughout its travel and shim further, if necessary

►*1955 CADILLAC WHEEL CYLINDER PRODUCTION CHANGE* Effective approximately Engine No 54000 a dish type metal expander is being used with wheel cylinder cups Expander minimizes contraction of cups due to variations in temperature and reduces possibility of air entering wheel cylinder when fluid cools and creates a slight vacuum in cylinder Wheel cylinders with expanders installed have copper plated bleed-

CONTINUED ON NEXT PAGE

BENDIX HYDRAULIC (Cont.)

er screw assembly. Early cars have a zinc dichromate plated bleeder screw assembly.

▷*1952-55 CADILLAC MASTER CYLINDER REPLACEMENT CAUTION:* Service replacement master cylinders for use on 1952-55 Series cars have filler cap designed for use with a remote filler reservoir. Drilled and tapped hole in center of cap for reservoir tube is plugged with red plastic cap. When replacing master cylinder on a 1954-55 Series car, plastic cap must be removed for attachment of remote filler pipe. When using a new master cylinder on a 1952-53 Series car without remote filler reservoir, filler cap must be discarded and filler cap from old master cylinder used.

▷*1955 HUDSON HORNET BRAKE PRODUCTION CHANGE & CORRECTION (To Eliminate Noise or "Clunk"):* Effective approximately October, 1955 a brake shoe return spring with greater tension (40 lbs.) will be incorporated in production to eliminate noise or "clunk" occurring during initial pedal application in reverse direction. New set, Part No. 3119175, including 4 springs (2 wheels), is available for installation on earlier cars.

▷*1955 HUDSON & NASH MASTER CYLINDER PRODUCTION CHANGE (To Correct "Spongy" Brake Pedal):* Master cylinder-to-pedal shaft brace, Part No. 3141435, may not fully engage groove at outer end of pedal shaft, permitting pedal shaft to flex within keyhole slot during application resulting in a "Spongy" brake pedal. Effective at following serial numbers, production enlarged two master cylinder attaching holes in brace to effect a full engagement of keyhole slot to groove in outer end of pedal shaft: Hudson Hornet V8, Y-1483; Hudson Hornet 6, X-1226; Hudson Wasp, W-1347; Nash Ambassador V8, V-1808, Nash Ambassador 6, R-743126; Nash Statesman, K-635418. At same time two original lockwashers on brace to master cylinder attaching screws were replaced with bite washers, Part No. 3138264. When condition occurs in field remove brace and elongate master cylinder attaching holes sufficiently to provide full engagement of keyhole slot to groove in outer end of pedal shaft. When reinstalling brace use two bite washers.

▷*1955 HUDSON WASP & NASH STATESMAN BRAKE CHATTER ON LIGHT PEDAL APPLICATION CORRECTION:* Chatter caused by drum distortion occuring when wheels secured to drums (ten wheel-to-hub contact ledges are not uniform in height). Generally, condition will improve with time and mileage. If chattering condition is severe, remove wheel and tire assemblies, and clean wheels as necessary. Color a 6½" square of plate glass with a bearing blue or colored crayon. Place the plate glass on the ten wheel-to-hub contact ledges, and oscillate the glass slightly to transfer coloring material to high ledges. With grinding equipment, gradually reduce high ledges to a point where it is not possible to place a .004" feeler gauge between plate glass and any one of the ten ledges. Repeat coloring operation as often as necessary. *Do not remove material in excess of .015" from any one of ledges.* If necessary, replace wheel. In cases where severe chattering is encountered it is possible that one or more drums have taken a permanent out-of-round set. Check drums, and in cases where out-of-round exists in excess of .005", a light cut be taken on drum lathe to bring drum within .005" out-of-round limit.

▷*1955 OLDSMOBILE BRAKE PRODUCTION CHANGE:* Beginning approximately May 15, a second type front and rear brake assembly was used in production. Primary change in new assembly is use of larger retracting spring and a new anchor pin. In rear brake assembly, new parking brake lever and pin assemblies are used to provide clearance for larger spring, and are held to the secondary shoe by a retaining clip. A new washer is also used in rear brake assemblies between parking brake lever and secondary shoe.

DESCRIPTION: Single anchor, hydraulic type. No eccentric used except on 1946-48 Pontiac models.

ADJUSTMENTS: Before attempting any adjustments, car should be placed on stands with wheels free. Brake pedal should operate freely and there should be no bind in hand brake lever or cables.

Brake Pedal Adjustment: This adjustment should conform with recommendations before any other adjustment is made. See Car Model below.

Buick—Clearance between pedal and underside of toeboard should be 1" (1946-54). 15/16" (1955).

Cadillac—Rubber grommet on pedal under toeboard should be compressed ⅜" (1946-48), just touch underside of toeboard (1949-55).

Hudson & Nash—Pedal free travel should be ¼-½" with master cylinder piston against stop. Adjust at master cylinder pushrod.

Oldsmobile—Adjust master cylinder pushrod to obtain a minimum of 3/16" free travel. Pedal rubber bumper should be compressed slightly.

Packard—Brake pedal should have ¼" free play with master cylinder piston against stop. Adjust at master cylinder pushrod.

Pontiac—Clearance from lower side of pedal pad to floor mat with master cylinder piston against stop should be 4¾" (Torpedo styles 1946-48), 5 3/16" (Streamliner styles 1946-48), 4 3/8-4 5/8" (All 1949-55).

▷*CAUTION:* On 1946-49 Cadillac and 1946-48 Packard, manufacturer recommends minor adjustment be made in same way as major adjustment (below). Minor adjustment only is made on 1955 Nash & Hudson models (anchor pin is fixed).

Hudson Mechanical Follow-Up Adjustment: *See "Hudson Mechanical Follow-Up".*

Minor Wear Adjustment (Exc. 1951 61, 62, & 60S Cadillac): Check and adjust brake pedal clearance, release hand brake lever, and see that cables are free and are not holding brake shoes against drum. At each wheel, expand brake shoes by turning adjusting screw up until wheel can just be turned by hand, adjust hand brake (cars where hand brake adjusted with shoes "expanded"-see Hand Brake Adjustment), then back off adjusting screw the number of notches or "clicks" as shown in table below. Check wheel for freedom of drag. If drag noted, tap backing plate to assist centralization of shoes, then recheck. If drag still exists, anchor pin adjustment may be in order. See Major adjustment.

1951 Cadillac 61, 62, 60S—Jack up car, remove adjusting hole cover from brake backing plate. Check wheel bearing adjustment and correct as necessary. Check to see that hand brake cables are not frozen in housing at rear wheels. Tighten ratchet adjustment until road wheel cannot be turned by hand, then back off ratchet 16 notches. Install adjusting hole cover. Adjust brake pedal free play.

Adjusting Screw Setting

Buick	① 15 notches
Cadillac (1946-49)	See Caution above
Cadillac (1950), 75 & 86 (1951)	12 notches
Cadillac 60S, 61, 62 (1951)	16 notches
Cadillac (1952-55)	14 notches
Hudson & Nash	14 notches
Oldsmobile	16 notches
Packard (1946-48)	See Caution above
Packard (1949-51)	16 notches
Packard (1952-55)	②
Pontiac (1946-48)	See below
Pontiac (1949-55)	14 notches

①—17 Notches maximum.

②—Turn brake adjusting screw up until wheel can just be turned by hand, then back off screw until wheel turns free.

1946-48 Pontiac Minor Wear Adjustment: (*NOTE*—Eccentric used). Loosen eccentric locknut on backing plate, rotate eccentric in direction of forward wheel rotation until .010" feeler is snug between lining and drum 1½" from each end of secondary shoe. Hold eccentric from turning, tighten locknut (*NOTE*—Clearance at both ends of shoe must be alike within .003" with smaller clearance at anchor end preferably. If not within clearance limits anchor must be relocated—See Major Adjustment below). Check for freedom from drag. Check brake equalization by depressing brake pedal until wheel with least drag can just be turned by hand, equalize by backing off adjusting screws not more than two or three notches. Do not tighten loose wheels.

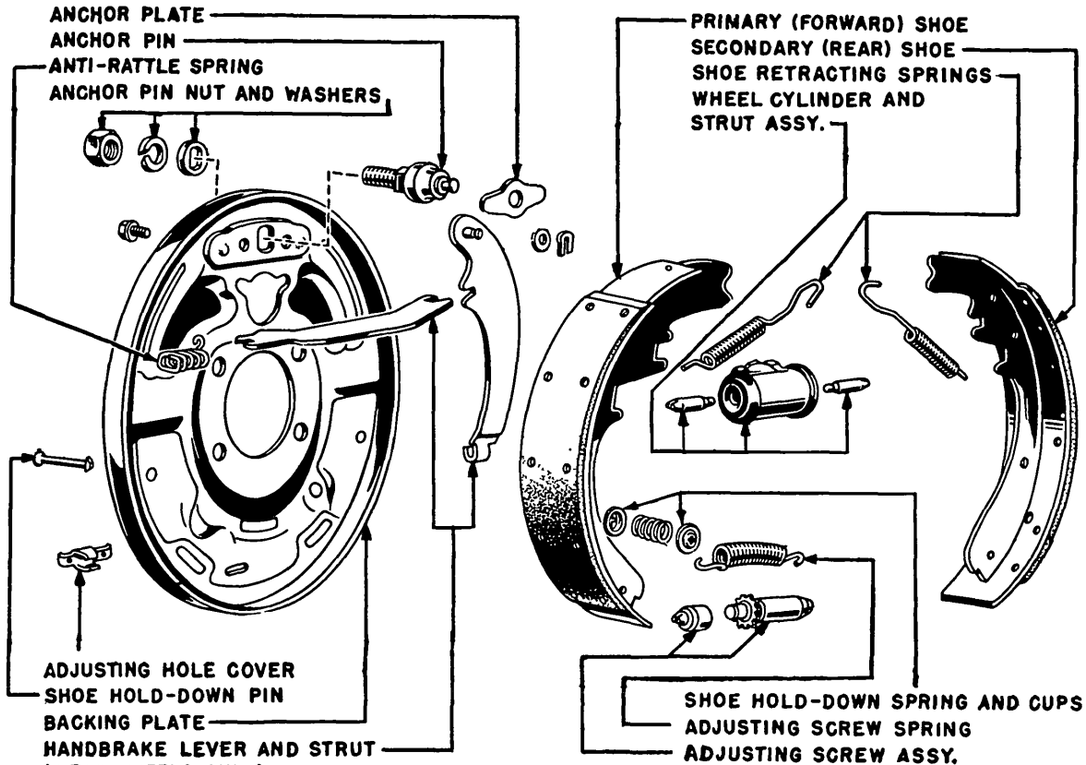
Major Adjustment (For Now Shoes, Relined Brakes or when Minor adjustment not satisfactory): Jack up all four wheels, loosen or disconnect parking brake cables at equalizer or intermediate lever, remove adjusting hole covers on backing plate and inspection hole cover on drums (remove wheels for access). Check Pedal Clearance (see Brake Pedal Adjustment). Adjust each wheel brake as specified by car manufacturer, given below. *CAUTION*—If hand brake cables not disconnected or loosened, shoes may be held "ON" by cables (if adjusted too tight) so that correct adjustment cannot be secured.

Buick—Turn adjusting screw up to expand shoes until wheel can just be turned with both hands (if wheel off, drum should just turn with long bar). Back off 15

CONTINUED ON NEXT PAGE

BENDIX HYDRAULIC (C nt.)

notches. (Max. 17 notches). Wheels should be free at approximately 6 notches. If not it indicates need for anchor pin adjustment or tight parking brake cables.



Anchor Pin Adjustment—Loosen anchor pin nut ½ turn just enough to permit anchor pin to slide in the slotted hole, *(CAUTION*—Loosening anchor pin nut too much will allow brake shoe spring to tilt pin), rap backing plate with hammer adjacent to anchor pin to insure anchor pin assuming central position between shoes, tighten anchor pin nut securely, then recheck drag. (If this has changed recheck anchor pin adjustment). Check and adjust hand brake (see Hand Brake Adjustment). Wheels should be free of any drag.

1952-55 Cadillac—Loosen anchor pin locknut ½ turn, tap anchor pin up with a hammer, then all the way down to bottom of its slot. Turn adjusting star wheel to expand brakes until wheel can just be turned with two hands. Tap backing plate near anchor pin to raise it to a central position between shoes. Check brake drag If centering of anchor pin has released brakes, increase expansion of shoes and reset anchor pin again. Repeat until there is no change in drag with change in anchor pin setting, then tighten anchor pin to 80-120 ft. lb. torque. Loosen star wheel 14 notches, plaoe .015" feeler through drum slot at bottom and rotate wheel until feeler is wedged between secondary shoe and drum. Primary shoe will be tight against drum for measuring secondary clearance. Reverse wheel rotation until .015" feeler is again at bottom and adjust star wheel to obtain .015" clearance. Clearance at top of shoe should now be .010". If upper clearance is greater or less than .010" loosen anchor pin locknut and reset anchor pin, tapping it up to increase clearance and down to decrease clearance. Reset clearance at lower end with star wheel and recheck upper clearance.

1951 Cadillac 61, 62, 60S—Loosen cable to hand brakes by loosening turn buckle at equalizer, just behind frame crossmember. Adjust brake pedal operating rod (free play). Then proceed as for Minor Adjustment above. Connect and adjust hand brake cables.

Cadillac (1946-50, 1951 75 & 86); Hudson & Nash (1946-54); Oldsmobile & Pontiac (1949-55)—Insert .015" feeler in slot 1½" from adjusting screw end of secondary shoe, turn screw up to expand shoes so feeler tightly gripped (to move primary shoe out against drum), then back off screw until only a slight drag is felt on the feeler gauge (will insure .015" clearance at this point). Check clearance at point 1½" from anchor pin end of this same secondary shoe. If .015" feeler does not have equal or slightly heavier drag at this point, adjust anchor pin (see notes below on slotted and eccentric type anchors) for correct .015" clearance at this point, tighten anchor pin nut to 75 ft. lbs. torque. Adjust hand brake, check and adjust brake pedal clearance (below).

Eccentric Anch r Pin— Pin has squared end. Can be turned with a wrench after nut has been loosened. Turn pin in direction of forward wheel rotation to decrease clearance. End of anchor pin is beveled and high point

BENDIX HYDRAULIC SINGLE ANCHOR BRAKE ASSY.

indicates high side of eccentric cam. Hold pin with wrench while tightening nut.

Slotted Anchor Pin Hole—Pin hole in the backing plate is slotted. To adjust, loosen anchor pin nut and tap pin out toward drum to decrease clearance.

1955 Hudson & Nash—No major adjustment. Anchor pin is fixed.

Packard—Insert a .015" feeler gauge through inspection hole in drum at point 1½" above lower end of secondary shoe. Expand the adjusting screw (star wheel) until a slight drag is felt on the feeler. Remove feeler and insert a .010" feeler through inspection hole in drum at a point 1½" from upper end of secondary shoe. If clearance not within limits, loosen anchor pin locknut and adjust anchor pin. Turn anchor in direction of forward wheel rotation to decrease clearance. At the same time readjust the adjusting screw to maintain .015" clearance at lower end of shoe. Hold anchor in set position and tighten locknut. Turn clearance adjusting screw (star wheel) until drum can just be turned with both hands, then back off screw 16 notches or "clicks" (1946-51), until drum turns freely (1952-55).

1946-48 P ntiac—*(NOTE*—Eccentric used). Loosen eccentric locknut, turn eccentric in direction of forward wheel rotation until .010" feeler is just snug at adjusting screw end of secondary shoe. Hold eccentric from turning, tighten locknut. Check clearance at anchor pin end of same shoe. If clearance not .010", adjust anchor pin (See Anchor Pin Notes above) until clearance at anchor pin end is exactly .010". Hold anchor pin from moving, and tighten locknut securely with 16" wrench. Recheck adjusting screw end clearance. Make any necessary readjustments at eccentric and anchor pin until .010" clearance secured at both ends of this shoe. Proceed as for Minor Adjustment (above).

Hand (Parking) Brake Adjustment: *CAUTION—Brake shoes must be expanded on some cars when adjusting hand brake cables.* Adjust each car as follows:

Buick—With rear wheel brake shoes xpand d so that wheels can just be turned by hand, place hand lever in fully released position, hold brake lever cable to prevent twisting and tighten nut at rear wheel cable sheave (under torque tube) to remove all slack from cables. Back off brake shoe adjusting screw 15 notches or "clicks" for correct shoe clearances and check wheel for drag.

CONTINUED ON NEXT PAGE

BENDIX HYDRAULIC (Cont.)

1946-48 Cadillac—Make sure service brakes are fully released. Loosen cables by loosening turnbuckle locknut at equalizer bar in X-member. With hand brake in fully released position, tighten turnbuckle until hand brake cable is taut. Tighten locknut. *CAUTION*—Do not change position of adjusting screw ("Star wheel") when adjusting hand brakes.

1949-55 Cadillac—Adjust locknut on equalizer link to obtain 1/8" clearance between the rear edge of the rear relay lever and end of slot in the frame X-member. **Do not expand rear brake shoes.** Adjust the equalizer lock nut until the rear brake cables are taut. Attach spring scale to hand brake lever and apply a pull of 50 lbs. Measure the distance the hand brake lever has moved from its fully released position. This should be 2 1/8-2 3/8". Readjust cable tension if necessary to obtain this amount of movement with 50 lb. pull. Recheck front cable for equalizer 1/8" clearance described above.

1946-54 Hudson—With brake shoes expanded so wheels can just be turned by hand, pull hand brake lever "ON" two notches and check clearance between hand brake cable lever and end of slot in lever guide plate on frame cross-member. If this clearance is not 1/8", loosen locknut and adjust hand brake cable clevis. Pull each rear brake cable taut and adjust clevis on forward end of cable so that clevis pin can just be inserted with all slack removed from cable. Connect cables, release hand brake lever, back off adjusting screw 14 notches for correct shoe clearance, check brake equalization.

1946-48 Nash—With rear brake shoes expanded against drum, pull hand lever "on" 2 notches, loosen two bolts on adjusting clamp (connecting lever and wheel cables), pull cables tight and tighten bolts. Return lever to "off" position. Back off adjusting screw in each wheel to free brakes and check equalization. See that hand brake lever on each wheel backing plate has 1/8" free travel with hand lever in off position. Equalize hand brakes by loosening rear bolt in cable adjusting clamp and applying hand brakes (this will allow cable to shift on adjusting clamp). Check position of hand brake cable guide on rear spring. Guide should be exactly 17½" to rear of spring front eyebolt centerline.

Nash Hand Brake Pull y Adjustment—When adjusting hand brake, first check position of hand lever cable pulley on front of dash (in engine compartment) and adjust cable position on pulley so that upper rear edge of pulley (segment type) is exactly 1 5/8" from top of pulley bracket upper mounting screw with hand brake lever in fully released position. Then adjust hand brake in usual manner (adjustment located at wheel cable equalizer clamp under car).

NOTE—On 4860 cars, and 4760 after Serial No. R-451662, an aligning pin hole is provided in the pulley bracket. The pulley can be correctly located by using J-1390 Gear Shift Aligning Pin.

1949 Nash—Pull hand lever "on" one notch. Remove all slack from cable at rear brake cable equalizer. Place hand lever in full "off" position and check rear wheel brakes for freedom from drag.

1950-54 Nash—**Do not expand shoes.** Pull hand lever "ON" exactly 3½" (measure from face of bracket to handle). At rear cable equalizer, loosen forward nut and tighten rear nut on hand brake lever cable fitting until rear brakes are fully applied, then tighten forward nut. Release hand brake lever and check brakes for freedom from drag.

1955 Hudson & Nash—Withdraw hand brake lever to rear to provide a 3½" clearance between hand brake lever handle and bracket face. With lever in this position, tighten hand brake cable at equalizer to a point where rear brakes are fully applied. This will prevent possible brake drag. To release parking brake, apply brake pedal pressure, turn parking brake handle counter-clockwise 70°, and push it into released position.

1946-52 Oldsmobile—Expand rear wheel shoes so that drums can just be turned, pull wheel cables forward to eliminate all slack, adjust clevises on forward ends of cables so that clevis pins can just be inserted with equalizer link held parallel to propeller shaft, connect cables (insert clevis pins with head toward top), back off adjusting screw in each wheel approximately 16 notches until wheels are free, check equalization.

1953-55 Oldsmobile—With hand lever **released** and service brakes properly adjusted, adjust hand brake front cable so that hand brake intermediate lever is held from seating itself on the end of the seat in the left "X" member by 1/32-3/32". Adjust rear cables to remove all possible slack without moving brake shoes from released position. Rear cables must not protrude into clevis more than ¾". The threaded part of front cable must extend entirely through front clevis. Distribute the adjustment between rear cables so that equalizer link is parallel to propeller shaft when clevis pin can just be dropped into place. Lock clevis jam nuts and insert clevis pins. Always install clevis pins with head on top.

Packard—Tighten adjusting screws until wheel can just be turned by hand. Pull hand lever to first notch on ratchet. Adjust clevis on hand brake cable so that the clevis pin can be easily installed without any slack in the cable. Release hand brake lever. Back off adjusting screw at each wheel 16 notches (1946-51), until wheel turns freely (1952 & Later). Apply hand brake and check equalization by turning each wheel by hand. If not equal, loosen adjusting screw on tighter brake. Replace hole covers and road test.

1946-48 Pontiac—Check brake cable tension by moving clevis pin at cross lever wheel cable spreader, pin should move up and down with thumb and finger pressure (hand lever in released position, rear wheel brake shoes not expanded), and both rear wheels should lock with hand lever in third notch. To adjust, remove cross lever clevis pin and engage pin in another of the several holes in the cable spreader (approximate setting), remove hand lever clevis pin and turn clevis on cable (exact setting) using extreme care not to twist the cable. To equalize wheel cables after adjusting, loosen clampscrews on wheel cable spreader at cross lever (if necessary pry clamp ears apart with a screwdriver so that cable free in spreader), apply brakes hard by pulling back on hand lever, tighten spreader clampscrews before releasing hand lever.

1949-55 Pontiac—Apply hand brake to fourth notch (1949-52), first notch (1953 & Later) and then check equalization. Loosen adjusting screw of tightest brake if not equal. If more than a few notches are required, loosen clamp screws on spreader and pull downward on the tight side of cable. This should equalize cable. Tighten spreader clamp screws while hand brake lever is still in the applied position. Brake cables are sufficiently tight if rear wheels can barely be turned by hand with lever in the fourth notch (1949-52), first notch (1953 & Later). When the lever is fully released, wheels should turn freely with cable pulled down approximately 1½" by gripping cable midway between conduit and clearance hole through frame X-member. When adjusting rear end of front cable for close adjustment for tension, be sure to turn clevis on or off cable end but do not twist cable. Coarse adjustment is secured by selecting the correct hole in the spreader.

RELINING BRAKES: Manufacturer recommends use of replacement shoes furnished with new linings. If shoes relined, use the same type lining as fitted originally (see Car Model page). Lining on primary and secondary shoes may be of different types (woven on primary, moulded on secondary, etc.) or of different lengths.

BRAKE DRUM GRINDING: If new .030" oversize shoe assemblies are to be installed, machining must not remove more than .030" on drum radius or .060" on diameter.

BLEEDING BRAKE SYSTEM OR OVERHAULING BRAKE UNITS: *See "Hydraulic Brake Servicing".*

TROUBLE SHOOTING: *See "Hydraulic Brake Troubl Shooting".*

HUDSON MECHANICAL FOLLOW-UP

Hudson, All Models Except Jet (1946-55)

DESCRIPTION & OPERATION: Consists of over-running mechanical linkage between brake pedal and hand lever equalizer bar plate or hand brake bellcrank, by which wheel brakes are set mechanically through hand lever linkage after movement of pedal is sufficient to operate brakes hydraulically. Acts as a reserve if hydraulic application fails or when pedal travel is excessive.

ADJUSTMENT: Adjust models as follows:

1946-47 Models—With master cylinder operating lever against stop (brake pedal stop), and rear brake cable equalizer bar plate against stop on bracket, loosen locknut on threaded follow-up rod below brake pedal, and turn adjusting nut until clearance between face of nut and front end of pushrod tube is 1¼", tighten locknut.

1948-54 Models—With brakes in fully released position, loosen locknut on threaded follow-up rod below brake pedal, and turn adjusting nut until clearance between rear side of brake pull rod slide link retainer pin and rear end of slot in slide link is 1¼", tighten locknut.

1955 Models—Disconnect cable from brake pedal and master cylinder piston pushrod from brake pedal. Place a 3½" spacer block between brake pedal rod pad and floor mat. Depress pedal rod until pad contacts spacer block; retain in that position and adjust mechanical follow-up cable length at clevis end so that clevis pin can be installed freely with no slack in cable.

BENDIX-LOCKHEED SELF-CENTERING

Frazer, All Models (1947-51)
Henry J, All Models (1951-54)
Hudson Jet (1953-54)
Kaiser, All Models (1947-55)
Nash "600", Series 4840 (1948)
Nash "600", Series 4940 (1949)
Nash Statesman (1950-54)
Nash Rambler (1950-55)
Willys, All Models exc. Jeep (1947-55)
Willys Jeep, CJ-3B & CJ-5 (1954-55)

►CHANGES, CAUTIONS, CORRECTIONS

►*1955 RAMBLER BRAKE SQUEAK CORRECTION (Due to Improper Lining-to-drum Contact):* If minor, sanding of lining surface to eliminate visible high spots, may eliminate condition If severe, shoe support plate contact area may be causing a rocking action on the three embossed ledges of support plate To correct, remove shoes from support plate and without use of return springs or hold down clips, place each shoe individually in its proper operating location on the three embossed ledges of support plate Check for any rocking action of shoe on support plate If found, grind off sufficient material from center of shoe contact edge to eliminate rocking action Grinding action should cover an area approximately 2" long on shoe edge where it contacts center embossed ledge of support plate It may also be necessary to **lightly** dress up the end shoe contact edges to provide proper shoe-to-support plate contact Lubriplate support plate embossed ledges and shoe pivot points Reinstall shoes Make anchor lip adjustment by bending anchor lip slightly toward brake support plate so that 15 lbs pressure is exerted by spring to retain shoes on support plate (this can be measured with spring scale hooked to end of shoe)

DESCRIPTION: These brakes are same design as other Lockheed Hydraulic Double Anchor types except for "self-centering" feature on each car as follows

Brake Shoe "Self-centering" Device—Each brake shoe fitted with rounded rocker on lower (anchor) end which bears against a solid block on the backing plate. This bearing block is machined with the rocker bearing surface aligned radially to the drum center so that shoes move radially out against the drum when brakes are applied and are automatically "centered with each brake application." Both shoes are held against the bearing block by a plain spring hooked in holes in each brake shoe web.

ADJUSTMENT: Before making adjustments, jack up all four wheels, check brake pedal clearance or free travel (see below), fully release hand brake and make certain that rear wheels are free, then adjust each wheel as follows.

►*CAUTION—Brake shoes must be "centralized" by several hard brake applications before adjusting.*

Brake Pedal Adjustment: Adjust master cylinder pushrod by loosening locknut and turning rod for following pedal free travel with master cylinder piston and pushrod back against stop.

Brake Pedal Free Travel

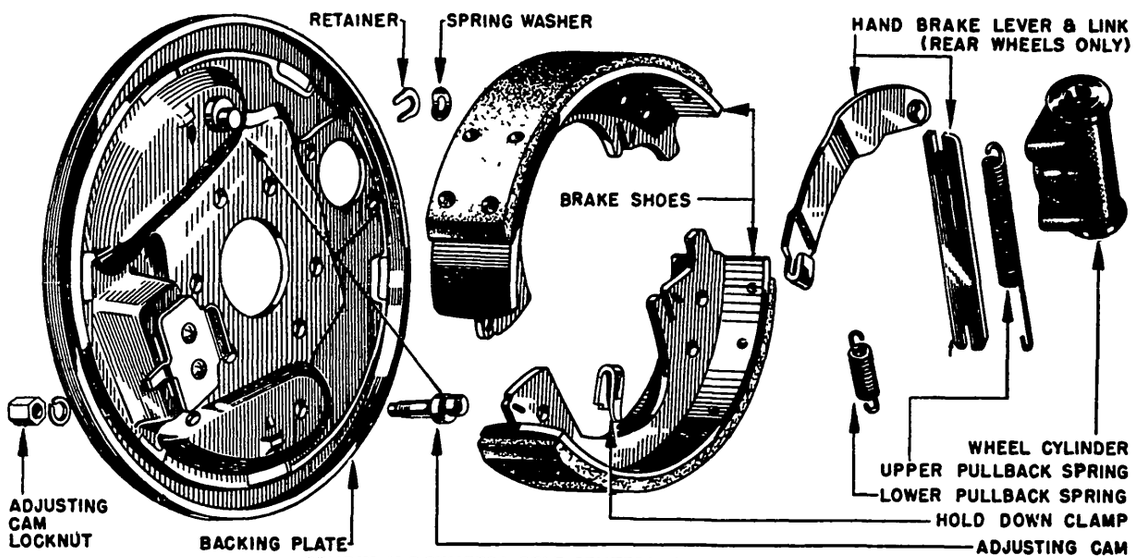
Frazer & Kaiser	½-¾"
Henry J	1-1¼"
Hudson Jet	¼-⅜"
Nash (All Models)	¼-½"
Rambler	¼-½"
Willys	½" min.

Brake Shoe Adjustment (For Wear or New Linings). Before making adjustments, centralize shoes by making a hard brake application (press firmly on brake pedal, then **release** pedal). At each wheel, adjust each brake shoe eccentric cam by turning cam out until shoe is tight in drum (with wrench installed on eccentric so that handle is upward, turn wrench away from wheel center-line), then back off eccentric until wheel just rotates freely without drag. Adjust each shoe eccentric in each wheel in this manner, then adjust parking brake (hand brake linkage) as directed below

►**Frazer, Hudson Jet, Kaiser Adjustment Note**—Eccentric cams have locknuts which must be loosened before adjustment can be made

Hand Brake Adjustment: *CAUTION—Adjust each model as follows*

Frazer & Kaiser (1947-48): After brake shoes adjusted, release hand lever, loosen locknut, turn clevis on rear end of lever cable at idler lever on frame cross-member to remove all slack from cables. When limit of adjustment reached, shift wheel equalizer-to-idler lever clevis pin to next set of holes in equalizer (three sets of holes), then make final adjustment at hand lever cable clevis as above. When properly adjusted, cables should have minimum slack without brake drag with hand lever in released position



Frazer (1949-51), Kaiser (1949-53)—With hand lever in released position, back off locknut on front cable end fitting in front of wheel cable connector under car, tighten adjusting nut (back of wheel cable connector), to remove all slack from cables, tighten locknut

Henry J—Place hand lever in fully released position Tighten nut on rear end of **front** cable at intermediate lever on frame cross-member until perpendicular distance between front cable and rear cable rod is 4⅝-4¾". Then pull hand lever "on" three notches and tighten rear cable by taking up adjustment nut at cable equalizer on rear end of cable rod until slight drag secured at rear wheels Release hand lever, check wheels for freedom from drag.

Hudson Jet—Pull hand brake lever "on" one notch, loosen clevis locknut, remove clevis pin, then shorten brake cable until slight drag is felt at each rear wheel Tighten locknut, secure clevis pin with cotter pin, release hand brake lever fully and check rear wheels for freedom from drag

Nash "600" Model (1948): With hand brake lever released, check position of hand lever cable pulley on front of dash (in engine compartment) and adjust cable position on pulley so that upper rear edge of pulley (segment type) is exactly 1⅝" from top of pulley bracket upper mounting screw (see Note below) Pull hand lever two notches "on" and leave in this position while adjusting cables. Loosen locknut on cable connector at wheel cable equalizer under car, remove all slack from cables, tighten locknut Place hand lever in fully released position and make certain that rear wheels free of any drag. NOTE—On 4840 cars, and 4740 after Serial No. K-170055, aligning pin hole provided in pulley bracket and pulley can be correctly located by inserting a J-1390 Gear Shift Aligning Pin through this hole.

CONTINUED ON NEXT PAGE

BENDIX (LOCKHEED) SELF-CENTERING BRAKE ASSY.

BENDIX-LOCKHEED SELF-CENTERING (C nt.)

Nash "600" Model (1949): Pull hand brake lever "on" one notch. Loosen forward nut and tighten rear nut on front cable fitting at rear cable equalizer to remove all slack from cables. Tighten forward nut, release hand lever, check rear wheels for freedom from drag.

Nash Statesman—Pull hand brake handle "On" exactly 3½" (measure from face of bracket to handle). At rear wheel cable equalizer, loosen forward nut, tighten rear nut on front cable fitting until rear brakes are fully applied, then tighten front nut to lock adjustment. Release hand lever and check rear wheels for freedom from drag.

Rambler (1950-54)—Pull lever "on" two notches, loosen front nut on adjusting rod at rear cable equalizer, tighten rear nut to remove all slack from cables, then tighten front nut to lock adjustment. Release hand lever and check rear wheels for freedom from drag.

Rambler (1955)—Pull hand brake lever to rear to provide a 3½" clearance between hand brake lever handle and bracket face. With lever in this position, tighten the hand brake cable at equalizer to a point where rear brakes are fully applied. This will prevent possible brake drag.

Willys—Pull hand lever "on" three notches, loosen front nut on connecting link between intermediate lever on frame cross-member and rear cable equalizer, tighten rear nut on link until slight drag noted at each rear wheel, then tighten front nut to lock adjustment. Release hand lever and check rear wheels for freedom from drag.

CJ-3B, CJ-5 Jeep—Hand brake is independent type. Located on propeller shaft at rear of transmission and controlled by hand lever on floor board.

Hand Brake (Adjustment for Wear)—Make certain that hand brake cable and linkage operate freely. Lubricate if sticking or binding is evident. Place brake handle on instrument panel in "off" position. Rotate brake drum until one pair of adjusting holes (three pairs located on back face of drum) is opposite the adjusting screws (notched wheels) within the brake. Insert a screwdriver or adjusting tool through each hole and turn each adjusting screw equally until the brake shoes are snug against the drum (NOTE—with tool against edge of hole as a fulcrum, move outer end of tool out away from center of driveshaft to expand shoes). **Back off each adjusting screw 7 notches** to provide correct shoe clearance.

SERVICING (Master Cylinder & Wheel Cylinders): *See "Hydraulic Brake Servicing" for complete data.*

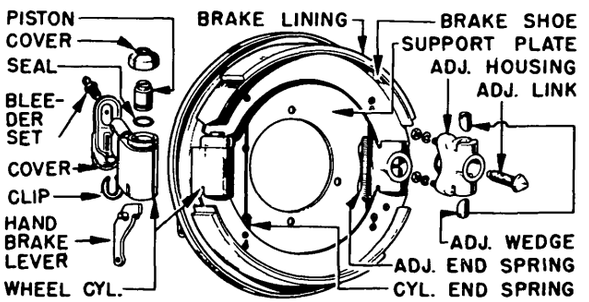
Bleeding Brake Lines: *See "Hydraulic Brake Servicing."*

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting."*

GIRLING HYDRAULIC

Metropolitan, Nash & Hudson Models (1954-55)

►*BRAKE APPLICATION NOTE:* When brakes are applied simultaneously by both the foot pedal (hydraulic) and hand brake lever (mechanical), an instant back-pressure on the pedal will be noticed by the operator. This is caused by the fact that initial shoe contact is made by the primary shoe (hydraulic application), and by the secondary shoe (mechanical application).



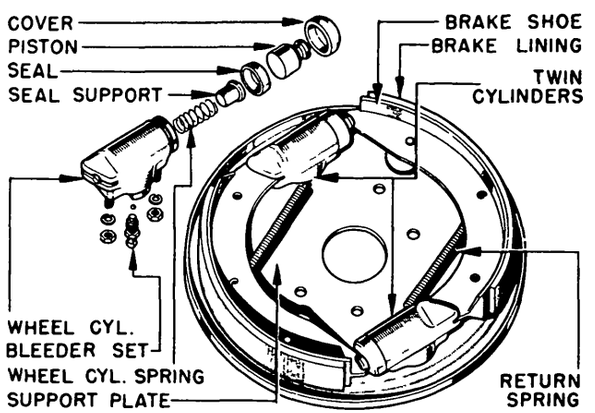
DESCRIPTION: Girling Hydraulic self centering with twin cylinders in front wheels and a single cylinder and an expanding wedge in rear wheels. Each front cylinder has locating slot for one shoe and its piston expands the other shoe. The rear wheel cylinder floats in the backing plate. The piston expands one shoe while movement of the cylinder body expands other shoe. Hand brake lever, in the rear brake assembly, pivots between secondary shoe and cylinder. Action of the lever on its pivot expands secondary shoe and moves cylinder and piston to expand primary shoe. Both front and rear brake shoe and lining assemblies rest on posts riveted to backing plates.

ADJUSTMENTS: There are four adjustments as follows:

Pedal Free Play—Raise car so all wheels are free and place hand brake lever in fully released position. Adjust pedal free play to 1/8" by adjusting length of master cylinder push rod.

Front Brakes—Back off both eccentric adjusters by turning them counter-clockwise. Turn one adjuster clockwise until brake shoe just drags and back off adjuster until wheel is free. Repeat this operation with other adjuster. Rotate wheel to be sure it is free of drag.

Rear Brakes—With hand brake fully released, turn square end of adjuster on each wheel backing plate clockwise until a slight drag is felt. Then loosen each adjuster two notches. Wheel should rotate freely.



REAR BRAKE ASSEMBLY

Parking Brake—The parking brake adjustment is made on the cable connector where it is attached to hand brake lever. *NOTE*—Do not make brake adjustments by alteration of the parking brake cable. Place parking brake lever in fully released position, remove inspection plate on side sill and disconnect the connector from hand brake lever. Push back rubber insulator and release locknut. Remove slack in cable by rotating connector and locknut in a clockwise direction. Reinstall and check operation.

BRAKE SHOE REPLACEMENT: When making bonded brake shoe replacement, the factory recommends that replacement of the shoe return springs be made at the same time.

Front Brake Shoe Replacement—Place suitable clamp or rubber band to prevent wheel cylinder from expanding when shoes are removed. Lift one shoe out of abutment slot of wheel cylinder, then release the other end from the wheel cylinder piston slot. Repeat operation for second shoe. Check and lubricate adjusters, lubricate tops of rest posts, and operating and abutment ends of new shoes. Fit new springs to shoes, place hooked end in the shoe and opposite end in holes backing plate near the abutment end of the same shoe. Install wheels and drums and adjust brakes.

Rear Brake Shoe Replacement—The same as for the front except the difference in return spring location. When removing the rear shoes, lift one end out of slot in the adjuster link and the other from wheel cylinder piston. Both shoes can then be removed with the springs. Install new springs with the shorter spring at the adjuster end. Locate one shoe in the adjuster link and wheel cylinder slot, then pull the opposite shoe into position. Adjust both service and parking brake assemblies.

FR NT BRAKE ASSEMBLY

LOCKHEED (WAGNER) HYDRAULIC SELF-ADJUSTING

Frazer & Kaiser Models (1949-50)—Some Cars
Studebaker, All Models (1947-53)

►CHANGES, CAUTIONS, CORRECTIONS

►*1947-51 BRAKE SHOE RETRACTING SPRING INSTALLATION:* Retracting spring is hooked to both front (primary) and rear (secondary) shoes on front and rear brakes. No shoes are "floating." For adjustments see "Adjustment" below.

►*1952 BRAKE SHOE RETRACTING SPRING INSTALLATION CHANGE OVER PREVIOUS MODELS:* Retracting spring is hooked to front (primary) shoes only with other end hooked to backing plate. Rear (secondary) shoes are "floating" type and require no adjustment. For adjustments of primary shoes see "Adjustment" below.

►*1953 BRAKE SHOE RETRACTING SPRING INSTALLATION CHANGE OVER PREVIOUS MODELS:* On **rear** wheel brakes of all models, brake shoe retracting spring is hooked to **both** the front (primary) and Rear (secondary) shoe **requiring adjustment of both shoes in rear wheels only.** On **front** wheel brakes of all models, brake shoe retracting spring is hooked to front (primary) shoes only (same as in 1952). For adjustments see "Adjustment" below.

►*1953 STUDEBAKER REAR BRAKE DRAG (Due to Pinched Parking Brake cable on Early Cars)*—In cases where rear brake drag is found, it is possible rear brake cable is pinched under spacer tube at parking brake equalizer bar. To free cable, loosen nut and reposition cable so it is not pinched by spacer tube (not used on later 1953 cars), retighten nut.

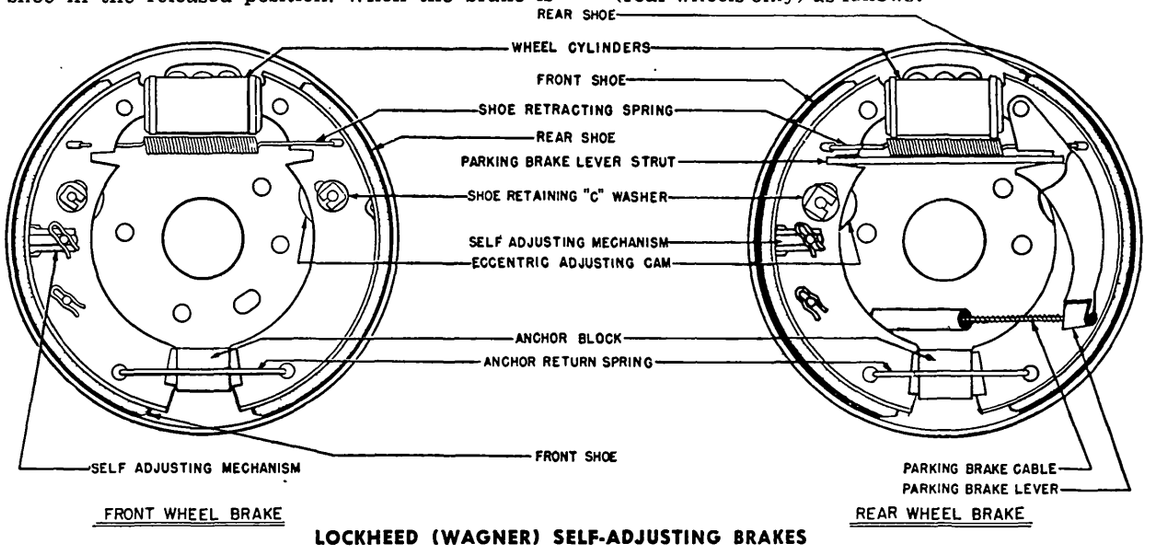
►*1953 COMMANDER & LAND CRUISER BRAKE LINING CHANGE*—Marshall Eclipse 2201-H8 replaces Marshall Eclipse 2607 used on earlier cars and can be used for service replacement on earlier cars. New lining is identified by green and red marks along lining edge. New lining will minimize "grabbing" on initial brake application after car parked. *See Car Model pages for lining specifications.*

►*1953 STUDEBAKER NEW PARKING BRAKE CONTROL HANDLE & CABLE INSTALLATION CAUTION*—It may be found that cable cannot be installed in plunger guide on 1953 Hard-Top or 5-Passenger Coupe models. In such cases it will be necessary to file or grind a ½" wide, 5/32" deep slot at top of plunger guide 2 9/32" from end so that tang on ferrule of cable assembly can be bent up into place.

DESCRIPTION: Two-shoe, hydraulic type with "self-centering" and "self-adjusting" brake shoes.

1947 Type Contact Plug & Spring—Spring is simple spiral type located in contact plug stem (see illustration).

1948 & Later Contact Plug & Spring—Spring is torsion type and actuates contact plug through adjusting lever pin (see illustration). This spring also retains self-adjusting mechanism on brake shoe and eliminates use of two hairpin cotters used for this purpose in 1947 assembly.



OPERATION: Self-centering Feature. Each brake shoe is fitted with a rounded rocker on the lower (anchor) end which bears against a solid block on the backing plate. This bearing block is machined with the rocker bearing surface aligned radially to the drum center so that the shoes move radially out against the drum when the brakes are applied and are automatically "centered" with each brake application. Both shoes are held against the bearing block by a plain spring hooked in holes in each brake shoe web.

Self-Adjusting Feature—Consists of an adjusting wedge and lever and contact plug assembly mounted on the shoe web of the **forward** brake shoe (rear shoe ordinarily does not require adjustment before relining of forward shoe is necessary and for this reason no automatic adjusting device is provided on this shoe). The contact plug (visible through the hole in the brake lining) is pinned on the adjusting lever which is pivoted on the shoe web. A spring-loaded adjusting wedge is mounted on the lever between the flat guide plate on the lever and the wedge guide on the shoe web. When the brake is released, the adjusting lever bears against the eccentric cam on the backing plate and holds the shoe in the released position. When the brake is applied, the entire mechanism moves out with the shoe until the contact plug strikes the brake drum. The contact plug and adjusting lever stop at this point and any additional movement of the brake shoe before the lining contacts the drum allows the spring to move the adjusting wedge inward to take up the clearance between the guide plate on the adjusting lever and the wedge guide on the shoe. This constitutes an "adjustment for wear" since the contact plug and adjusting lever have assumed a new relation with respect to the brake shoe and limit the movement of the shoe (when the brakes are released) to a position corresponding to the original drum clearance as set up by the initial adjustment of the eccentric cam when the shoes were installed. When the entire range of adjustment has been utilized, subsequent wear of the lining results in increased brake pedal travel which calls the operator's attention to need for relining of brakes.

1952-53 "Floating" Secondary Shoes—Brake shoe retracting spring is not hooked to the shoe (spring hooked to backing plate behind shoe) and the shoe is allowed to lie close to the drum at all times. A "spring" type washer has been installed under the C-washer retaining the brake shoe on the eccentric pin to provide additional friction and prevent the shoe from "jarring" away from the drum. The brake shoe adjusting eccentric remains in the "off" position at all times and is not used for adjusting the secondary shoe. *(CAUTION—If the brake shoe can be easily "jarred" away from the drum, replace the spring type washer).*

ADJUSTMENT: *CAUTION—Check operation of self-adjusting mechanism before making adjustments.*

Self-Adjusting Feature—An initial adjustment is required when new linings are installed. No further adjustment is required during the life of the lining (self-adjusting feature and self-centering feature automatically compensate for lining wear each time brakes are applied). After new or relined shoes are installed, check self-adjusting feature and adjust eccentric cams (all wheels) and parking brake (rear wheels only) as follows:

LOCKHEED (WAGNER) SELF-ADJUSTING BRAKES

Brake Pedal Clearance Adjustment: Pedal clearance or free travel must be correct to insure master cylinder pushrod being back against its stop for correct compensating action when brakes released. Adjust by loosening locknut on pedal connector rod and turning large adjusting nut.

Brake Pedal Clearance or Free Travel

Frazer & Kaiser	½-¾"
Studebaker (1947-51)	⅛-¼"
Studebaker (1952-53)	1/16-3/16"

Self-Adjusting Mechanism Check: With shoes completely assembled on the backing plate, press contact plug in and completely retract wedge (pull out on adjusting wedge until it is felt to strike the stop), release contact plug, then release adjusting wedge. Press in on contact plug and note wedge action. Wedge should move in to take up the clearance. Repeat this test. Check contact plug spring tension by pressing and releasing contact plug while holding adjusting wedge in retracted position. Both tests should reveal positive spring action. NOTE—Self-adjusting mechanism should be overhauled if parts do not function correctly. CAUTION—Adjusting wedge must be in fully retracted position (pulled

CONTINUED ON NEXT PAGE

LOCKHEED SELF-ADJUSTING (C nt.)

out against stop) after tests are made and before initial adjustment of brake shoes is attempted.

Initial (Eccentric Cam) Adjustment: *CAUTION—On 1952 models secondary (rear) shoe eccentric cams must be placed in the "OFF" position. No other adjustments required on these cams. On 1953 models secondary (rear) shoe eccentric cams, of FRONT WHEEL BRAKES ONLY, must be placed in the "OFF" position. No other adjustment required on secondary (rear) shoes of front wheel brakes.*

For all other shoes, make certain that hand brake lever fully released, then proceed as follows:

►*BRAKE ADJUSTING NOTE—If adjustment required in service (noted by loss of pedal reserve), check self-adjusting mechanism, then adjust as follows:*

Adjusting Forward Shoes (with Self-adjusting Feature). Place adjusting wrench on hexagonal head of eccentric cam adjuster with wrench handle upward. Turn brake drum in a forward direction and at the same time move wrench handle outward until shoe has a decided drag on the drum (this will permit shoe to center itself), then back off eccentric cam adjuster until wheel turns freely without drag.

NOTE—Eccentric cam adjuster is friction type and will slip on the shaft if excessive pressure is applied. This slippage is designed to prevent damage to the self-adjusting mechanism. CAUTION—If adjuster slips so freely on the shaft after extended service that the brakes cannot be adjusted properly, turn the eccentric cam by inserting a screwdriver blade in the slot in the end of the shaft.

Adjusting Rear (Secondary) Shoes (All 1951, Rear Wheel Only 1953)—Place adjusting wrench wrench handle upward. Turn brake drum in a backward direction and at the same time move wrench handle outward until shoe has a decided drag on the drum (this will permit shoe to center itself), then back off eccentric cam adjuster until wheel turns freely without any drag.

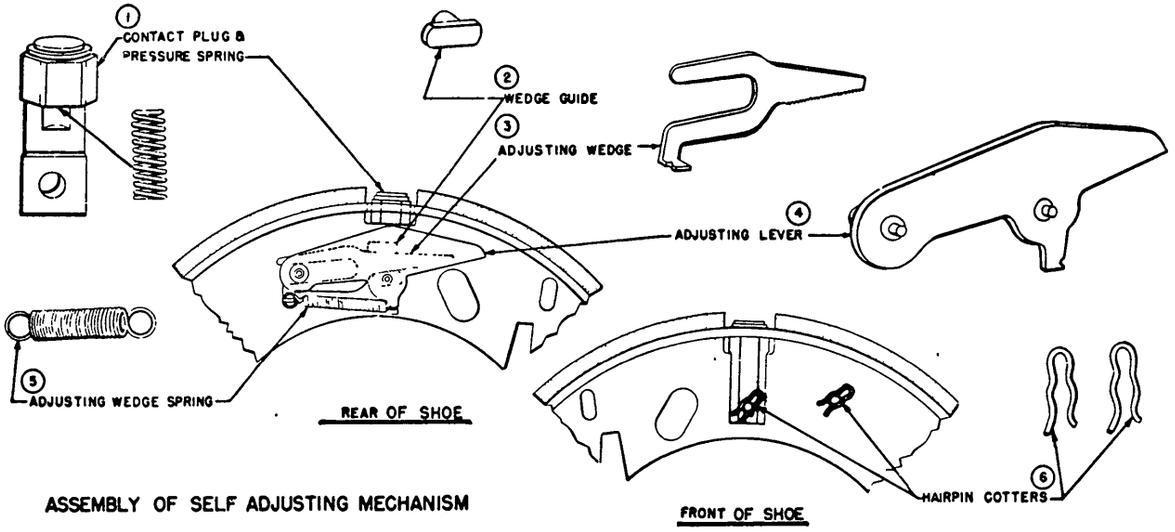
Adjusting Rear (Secondary) Shoes (All 1952, Front Wheel Only 1953)—See that adjusting eccentric is in full "OFF" position. These "floating" shoes REQUIRE NO ADJUSTMENT.

Parking Brake Adjustment: After adjusting brake shoes, adjust hand brake linkage as follows:

Frazer & Kaiser—With hand lever in released position, loosen locknut and tighten rear nut on forward cable fitting at wheel cable equalizer yoke to take up all slack in cables. Make certain that brakes do not drag.

Studebaker—Pull hand lever "on" four notches, back off front nut and tighten rear nut on cable clip under car until heavy drag noted at rear wheels, tighten front nut. Release hand lever and check wheels for freedom from drag.

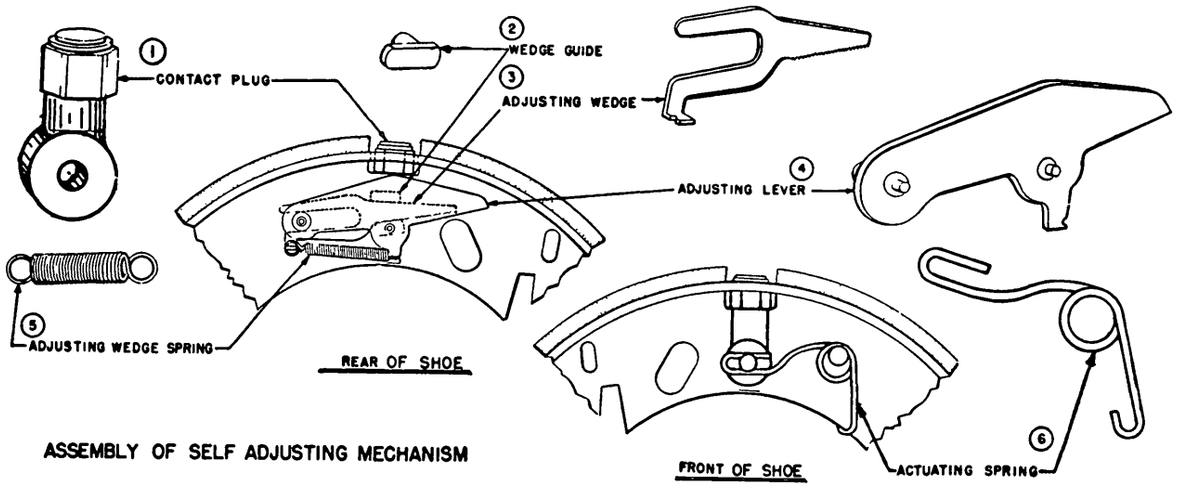
Hill-Holder & Anti-creep Adjustment: If these units installed, see separate data on each type for adjustment instructions.



RELINING BRAKES: Brake shoes should be removed for relining when increased brake pedal travel indicates limit of automatic adjustment reached and satisfactory shoe adjustment not possible.

►*CAUTION—Continued use of brakes after self-adjusting mechanism has reached limit of travel will result in increased lining clearance and pedal travel and in wear of the contact plug tip.*

Brake Shoe Removal: Install clamp across brake cylinder boots in each wheel to retain wheel cylinder pistons. Remove shoe retracting spring and anchor return spring. On rear wheel brakes only, pull parking brake lever toward center of wheel and unhook cable. Remove "C" washers from end of eccentric cam adjuster shaft on each brake shoe web. Pull heel of shoe away from anchor block, lift up on shoe until it clears eccentric cam adjuster shaft, pull toe of shoe out to clear cylinder boot.



Self-adjusting Mechanism Disassembly—Remove two hairpin cotters (1947 Models), actuating spring (1948-53 Models) from adjusting lever pins on contacts shoe web and hold in this position, disconnect adjusting wedge spring, lift off adjusting lever, remove adjusting wedge, wedge guide, con-

ASSEMBLY OF SELF ADJUSTING MECHANISM

1947 TYPE SELF-ADJUSTING MECHANISM

ASSEMBLY OF SELF ADJUSTING MECHANISM

1948 & LATER TYPE SELF-ADJUSTING MECHANISM

LOCKHEED SELF-ADJUSTING (Cont.)

tact plug (and spring on 1947 models). NOTE—Discard old plug and install new part when relined shoes are installed. All other self-adjusting device parts should be cleaned, inspected for wear, and reinstalled if not worn or damaged.

Relining Brake Shoes: Car manufacturer recommends that Lining Kits (with predrilled linings, new contact plugs, and plug adjusting gauge) be used when relining brake shoes. If predrilled linings not used, an accurately located ¾" hole for contact plug clearance must be drilled in lining for each forward brake shoe (high-speed edge hole saw recommended for this purpose) When riveting lining to shoe, make certain that there is a uniform clearance of 1/16" between the edge of the hole in the lining and the hole in the brake shoe.

►*CAUTION—If shoes ground after lining installed, do not install self-adjusting mechanism until after grinding completed.*

Self-Adjusting Mechanism Assembly: See illustration for proper location and order of installation of these parts. **Always use a new Contact Plug with new linings.** Press down on contact plug while installing adjusting wedge (pin on wedge must enter hole in contact plug) and make certain that lever is flat against shoe web. Push adjusting wedge in as far as possible while installing wedge-to-lever spring and use great care not to damage spring. After completing assembly, retract adjusting wedge (pull wedge out as far as possible), adjust contact plug:

►*CAUTION—Actuating spring must be installed as shown in order to provide proper tension on contact plug and to retain self-adjusting mechanism parts on shoe.*

Contact Plug Height Adjustment—Make certain that adjusting wedge fully retracted, clamp brake shoe assembly in vise with contact plug upward and vise jaws gripping adjusting lever so that contact plug cannot move inward, install gauge tool, FL-1047, on contact plug (gauge is .005" template designed to fit over end of contact plug), file end of contact plug down flush with face of gauge.

►*CAUTION—Contact plug must be depressed (flush or one notch below lining surface) when adjusting forward shoes (will cause over-adjustment of brake shoe on first application otherwise).*

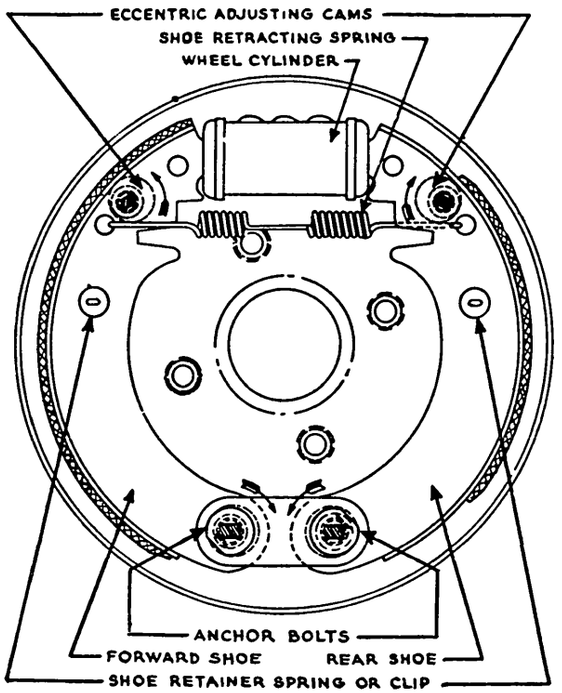
Brake Shoe Installation & Adjustment: Do not lubricate any part of the brake. When installing shoes, turn eccentric cam adjuster to released or minimum adjustment position, make certain that adjusting wedge of self-adjusting mechanism is in fully retracted position, centralize shoes approximately (by hand) after shoe retracting springs are installed. Check self-adjusting mechanism and adjust each brake shoe. *For retracting spring installation see Installation Notes under "DESCRIPTION" and for adjustments see "ADJUSTMENT."*

SERVICING: Brake Shoes & Lining. *See Relining Brake data above.*

Master Cylinder & Wheel Cylinders: *See "Hydraulic Brake Servicing."*

Bleeding Brake Lines: *See "Hydraulic Brake Servicing."*

TROUBLE SHOOTING: *See "Hydraulic Brak Trouble Shooting."*



LOCKHEED HYDRAULIC DOUBLE ANCHOR

Crosley, CD & VC (1950-52)
Nash "600", All Models (1946-47)
Willys Jeep, CJ-2A, & 3A (1946-53)

Willys Model Note—Eccentric adjusting cams are fitted with locknuts which must be loosened before adjustments can be made (eccentrics held by spring tension on other models). Drums are provided with slots which are accessible after wheels removed so that lining clearances can be measured directly by inserting feeler gauge through slot.

DESCRIPTION & OPERATION: All Wheel Brakes. Two shoes per wheel, mounted on independent ec-eccentric anchor pins at the lower or "heel" end and bear directly against the opposed pistons of stationary wheel cylinder at the upper or 'toe' end. Shoes are forced out against drum at toe end by fluid displaced from master cylinder and flowing through brake lines to wheel cylinder when brake pedal is depressed. No self-energizing action is employed and self-energizing effect of forward brake shoe ordinarily offset by using longer length lining on this shoe or by using 'stepped' wheel cylinders with smaller diameter forward shoe piston and larger diameter piston for rear shoe. Brakes are returned to 'off' position against eccentric stops by retracting spring connected between shoes at toe end.

Wheel Cylinder:—Rigid type mounted on backing plate with opposed pistons bearing directly on toe ends of brake shoes. Pistons sealed by rubber caps held against piston head by central spring.

LOCKHEED DOUBLE ANCHOR BRAKE ASSY.

Master Cylinder:—Compensating type with integral supply tank. Supply tank is directly above master cylinder and is connected to it by two ports (1) bypass port uncovered when piston is in 'off' position so that fluid may flow freely in or out of master cylinder to compensate for any loss, and to prevent back-pressure due to expansion of fluid in system and (2) supply port by which additional fluid is drawn down and through holes in the piston and past the lip of the piston packing cup when brake pedal is released so that cylinder is always full of fluid and ready for repeated brake action even before fluid in system is returned to master cylinder by retracting wheel cylinder pistons caused by shoe springs. Master cylinder requires no attention other than keeping supply tank more than one half full of fluid at all times. Brake pedal clearance should be checked (see directions below) but will not change in service.

NOTE—Wheel cylinder must be 'bled' whenever brake line to that particular wheel is disconnected, and entire system (all four wheels) must be 'bled' whenever brake lines are disconnected at master cylinder to remove all air in system and correct springy brake action.

Bleeding Brake System—Refer to Hydraulic Brake Servicing data for complete information.

Hand Brake:—When incorporated in rear wheels consists of cable operated lever pivoted on one brake shoe and connected to other shoe through link or strut so that toes of both shoes are forced out against drum when hand lever is applied. Adjustment should be checked whenever brake adjustments are made.

ADJUSTMENT:—Before making adjustments, jack up all four wheels, check brake pedal clearance or free travel (See Brake Pedal Adjustment below), release hand brake and make certain that rear wheels are free, check pedal travel as follows·

Brake Pedal Adjustment:—Pedal clearance or free travel before master cylinder piston begins to move should be ¼-½" (see Notes below for special settings on some cars) to insure master cylinder piston being back against its stop for correct compensating action with brakes released. To adjust, remove clevis pin in pedal link, hold piston rod from turning with wrench on hexagonal end and loosen locknut on link, turn link in or out of piston rod.

Willys Jeep Model (1946 On). Pedal free travel should be ½" minimum. Adjust by disconnecting pedal rod at brake pedal, loosening locknut on opposite end of rod, and turning rod in or out of piston link in master cylinder.

Minor Adjustment (For Wear):—Jack up all four wheels, release hand lever, see that rear wheels are free. At each wheel, turn up eccentric on each shoe (move wrench toward wheel rim when installed on eccentric nut upward) until shoe contacts drum, then back off eccentric slightly until wheel rotates freely in both directions with no drag. Eccentric held in position by spring tension. Check hand brake setting and adjust if necessary.

CONTINUED ON NEXT PAGE

LOCKHEED HYDRAULIC (C nt.)

Willys Note—On this model, eccentric is locked by a locknut on the backing plate. Locknut should be loosened before eccentrics are adjusted. Hold eccentric from turning while tightening locknut after adjustment completed. On all other models, eccentrics are held in position by spring tension and locknuts are not used.

Major Adjustment (For New Linings):—With shoe and lining assemblies installed and brake drum in place, loosen anchor pin locknuts at bottom of backing plate, then turn eccentric anchor pins toward each other and down until shoes are set to proper clearance as determined by feeler gauges. Recommend shoe setting is .005" (.004" Nash) clearance at heel (lower end) and .008" at toe (upper end).

Willys Note—On early models, a slot was provided in brake drum for checking these clearances. This slot was eliminated in later models.

Parking Brake:—Adjust when service brakes are adjusted or new shoes installed. Adjust as follows:

Crosley—Pull hand brake half way on. Adjust hand brake linkage so clevis pins just enter clevises when all slack has been removed from cable. Release hand brake and check to see that rear wheels are free of any drag.

Nash—Set hand lever 2 notches "on", loosen locknuts on wheel cable spreader (hand lever cable connection), remove all slack from cables by pulling forward on wheel cables and to rear on hand lever cable, tighten locknuts. Release hand lever and check to see that rear wheels are free of drag.

Willys—Hand brake is independent type.

RELINING BRAKES:—See car model page for lining type and length and instructions where lining of unequal lengths used on forward and rear shoes in same wheel. Linings should be faced or ground concentrically after installation.

Sh e Removal:—Shoes held in place by coil spring retained by plain washer and 'C' type washer on each shoe. To remove shoes, pull out 'C' washer, disassemble plain washer and spring, take off return spring freeing shoes at toe end (use piston clamp on wheel cylinder and do not depress pedal with shoes disconnected). Remove 'C' washers on anchor pins, slide shoes off.

SERVICING: Master Cylinder & Wheel Cylinders. ***See "Hydraulic Brake Servicing" for complete data.***

Bleeding Brake Lines: ***See "Hydraulic Brake Servicing."***

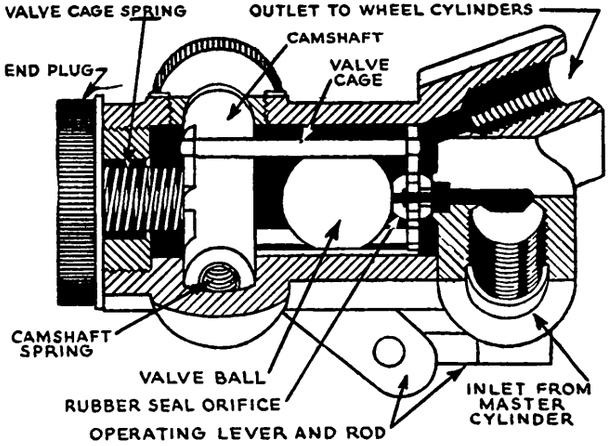
TROUBLE SHOOTING: ***See "Hydraulic Brake Trouble Shooting."***

HILL-HOLDER & NOROL

Std. or Optl. Equipment On:

ALL CAR MODELS WITH HYDRAULIC BRAKES

DESCRIPTION:—These units consist of a gravity and clutch pedal controlled check valve in a housing which is ordinarily mounted directly on the end of the hydraulic brake Master Cylinder so that the check valve is in the brake line between the master cylinder and the wheel cylinders. The valve ball is free to roll endwise in the valve cage (when unit tilted by car being on an incline) while the valve cage itself is moved endwise by a cam lever linked to the clutch pedal.



OPERATION:—The valve cage with the rubber seal orifice is normally held away from the valve seat by the clutch pedal controlled camshaft (with the clutch engaged) so that the valve is open and brake operation is conventional When the clutch is disengaged, the rotation of the camshaft permits the spring behind the valve cage to force the cage back so that the rubber seal seats against the valve seat If the car is pointed uphill, the ball within the valve cage rolls down against the rubber seal, closing the orifice within the seal so that the brake fluid in the lines is prevented from returning to the master cylinder and brakes are held 'on' even though brake pedal is released When the clutch is engaged, the valve cage is pulled away from the valve seat uncovering the return passage to the master cylinder and releasing the brakes If the car is on a level road or pointing downhill, the ball will not close the rubber seal orifice

ADJUSTMENT:—Operating lever position must be checked (to insure correct timing of brake release when clutch is engaged) whenever clutch pedal is adjusted See Clutch pedal adjustment instructions on car model page for special instructions Adjust as follows

Adjustment:—Check setting by applying brake on slight incline with clutch disengaged, then shift into low gear, engage clutch slowly and note point at which brakes release. If brakes release too soon and car has tendency to roll backward, loosen locknut and turn adjusting nut on end of control rod away from pedal to lengthen rod. If brakes release late and engine has tendency to stall, turn nut in to shorten rod. Tighten locknut and check setting.

Mounting:—The unit must be mounted in a level position on car frame. To check, place spirit level on bosses on top of hill-holder body casting with car standing on level floor. Unit must be leveled lengthwise (place spirit level on two bosses on top of unit), and crosswise (place spirit level crosswise on one boss).

SERVICING: Before disassembly, mark shaft and lever and replace in same position Remove ball chamber head plug and spring, withdraw camshaft being careful not to lose camshaft spring, withdraw ball cage assembly. In reassembling unit, see that ball cage is installed with two large ball rail rods underneath camshaft, and that camshaft spring is in place at inner end of camshaft

HILL-HOLDER & NO-ROL CONTROL UNIT

WAGNER-LOCKHEED SELF-CENTERING

Studebaker, All Models (1954-55)

►CHANGES, CAUTIONS, CORRECTIONS

►*BRAKE LINING REPLACEMENT CAUTION:* On early production cars, some long and some short primary brake shoe linings were used on either front or rear wheel brakes. When it is necessary to replace primary shoe linings on a front or rear wheel, the other front or rear wheel should be inspected and the lining on the primary shoe also replaced, if necessary, to obtain same length primary lining on both front and rear wheels.

►*1954-55 PARKING BRAKE LEVER CLIP INSTALLATION CAUTION (To Prevent Breakage & Falling Off of Clip):* Above condition is partially result of assembling in reverse or incorrect order the springs that return the shoe assemblies. Assemble rear shoe return spring to the shoe and its spring retainer first, then assemble front shoe return spring.

DESCRIPTION: Wagner Lockheed Hydraulic self-centering and self-energizing type (with Bendix type brake shoe assemblies). Brakes are not self adjusting, and new adjustment procedure is required. New self-centering device used.

Self-centering Device—The upper (anchor pin end of each brake shoe rests against a wedge-shaped anchor block which is mounted on fixed brake anchor pin (shoes do not contact anchor pin directly) so that the shoes are free to move radially. The wide edge of the anchor block is toward the top. When the brakes are applied, the lining surface pressure tends to force the shoe to adjust its position on the block and center itself in the drum. This centering action takes place on light, or heavy brake application and is continuous with drum expansion. The anchor plate aids in keeping the shoes properly aligned at the self-centering block.

Adjusting Device—Consists of a "star wheel" adjusting screw and stud assembly mounted between the lower ends of the two brake shoes (similar to Bendix-Duo-servo brake shoe assemblies). Adjusting screw spring serves a dual purpose, holding the shoes against notches of adjusting screw, and binding against ratchet on screw to serve as a screw lock.

ADJUSTMENTS: Place car on stands so that all four wheels are free. Check master cylinder and see that fluid level is ½" below top of cylinder. Place parking brake handle in fully released position. Adjust as follows:

Brake Pedal Free Travel Adjustment: 1/4-3/8" pedal free travel measured at brake pedal pad. To adjust, loosen locknut on brake pedal-to-master cylinder rod and turn master cylinder push rod until 1/4-3/8" pedal free travel exists before the pressure stroke starts.

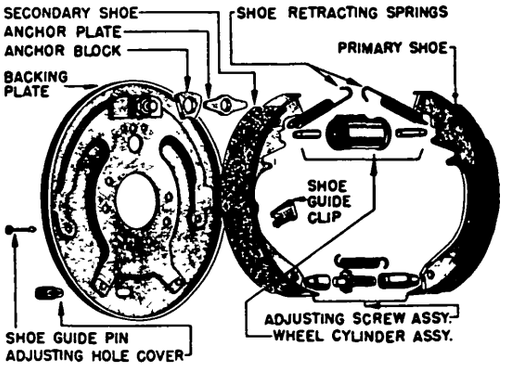
Brake Sh Adjustment: Remove adjusting hole cover from backing plate, insert screwdriver or special adjusting tool through adjusting hole and turn adjusting screw to expand shoes until drum is just locked (pivot tool on edge of slot, move handle upward to expand shoes). Then back off the adjusting screw 8 notches or "clicks" (more if necessary) until drum is free of any drag. Replace adjusting hole cover, adjust parking brake.

Parking Brake Adjustment: Set control handle four notches from the fully released position. Adjust rear wheel cables at equalizer on frame side rail by backing off front nut and tightening rear nut until all slack is removed from cables and a heavy drag noted when rotating rear wheels by hand, tighten front adjusting nut. Release control handle fully and see that wheels are free of any drag.

RELINING BRAKES: *See Replacement Caution above.*

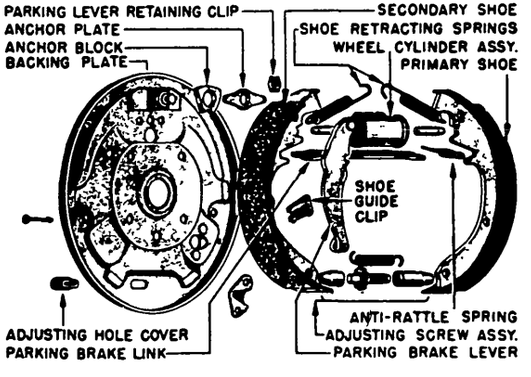
BRAKE SHOE REMOVAL & INSTALLATION:

Front Brake Shoe Removal: Place wheel cylinder clamp across cylinder boots. Remove adjusting screw spring and assembly. Hold guide pin against backing plate and remove clip. (Clip on the shoe whose return spring is on top at the anchor pin). Pull shoe out at end away from cylinder to release shoe from cylinder push rod. Move shoe away from backing plate off anchor block to relieve spring tension. Remove spring and shoe. Repeat this operation for other shoe. If Tool J-1681 Remover and Replacer available, remove springs first, then clips, and spread shoes out of wheel cylind- push rods. Slip adjusting screw off shoes and remove adjusting screw spring.



Front Brake Shoe Installation: Lubriplate wear surfaces by backing plate. Check anchor block installation. The curved side must contact primary shoe and arrow must point toward primary shoe. Hook return spring on shoe table, with outer other end of spring on anchor block pin and shoe against anchor block. Move shoe down to pivot on anchor block and pin, start web into cylinder push rod, push shoe toward backing plate, stretching spring. Align guide pin holes and install pin and clips, with pin seated in clip. Hook other spring on other shoe and anchor pin, placing shoe web above cylinder push rod. Pull lower end of shoe away from spindle and slide shoe down on anchor block behind anchor block guide, inserting web in cylinder push rod at the same time. Install guide pin and clip. Spread shoes and install adjusting screw assembly and install spring. If Tool J-1681 Remover and Replacer available, hook adjusting screw spring and adjusting screw in position. Place shoes on backing plate, engage webs in cylinder push rods, install guide pins and clips. Install anchor block and guide and use tool to install springs. Remove Cylinder clamps. Rotate adjusting screw to fully released position, center shoes to aid in brake drum installation. Install drum and adjust wheel bearings. Adjust clearance as shown in ADJUSTMENTS above.

Rear Brake Shoe Removal: Install cylinder clamps, pull parking brake lever toward axle shaft and unhook cable. Spread shoes, disengage parking brake link, remove link and anti-rattle spring. Then follow procedure listed above for front brake removal. To remove parking brake lever from hole, remove spring clip and slip lever pin out of web. *NOTE*—The lever is mounted on outer side of web (Champion) and inner side of web (Commander).



Rear Brake Shoe Installation: Install parking brake lever with clip securely in place. Then install shoes as described for front shoes above. Place anti-rattle spring in actuating link. *NOTE*—On Champion, spring installed on end of link with largest offset. Insert link between shoes engaging front shoe with end having anti-rattle spring. Connect cable, remove clamps, install drums and adjust clearance as shown in ADJUSTMENTS above.

Chrysler 8, Exc. C47 Imperial (1949)
Chrysler 8, Exc. C49 Town & Country, C50 Imperial (1950).
Chrysler 8, Exc. C53, 59, 66, 70 Imperial (1951-55)
DeSoto, All Models (1946-55)
Dodge, All Models (1946-55)
Plymouth, All Models (1946-55)

►CAUTIONS & CORRECTIONS

►*1949-54 POWER BRAKE CAUTION:* Vacu-Ease Power Unit Standard or Optional on Chrysler (except Disc Brake equipped cars), DeSoto, Dodge, and later Plymouth cars. *See "Chrysler Vacu-Ease Power Unit".*

►*1955 POWER BRAKE CAUTION:* Power Brake Standard on all Chrysler Models except C-67 (Windsor). Optional on Chrysler Windsor, DeSoto, Dodge, and Plymouth Models. *See "Chrysler & Imperial, DeSoto, Dodge, Plymouth Power Unit".*

►*BRAKE SQUEAL OR ABNORMAL LINING WEAR: Cam pins which are too high will cause brake shoe misalignment causing brake squeal and abnormal lining wear. Correct as follows:*

Cam Pin Height Check & Correction—To check cam pin height alter brake adjusting Tool MT-19-L and follow procedure below.

1) To alter Tool MT-19-L, drill and tap gauge holder and install wing type screw so that gauge can be secured to the bushing adapter.

2) (Front wheel). Place gauge on spindle with shoe removed and set gauge to height of wheel cylinder anchor lug. Check height of cam against this gauge setting. Cam pin should be equal or less than this reading.

3) (Rear wheel). Place gauge on axle with shoe removed and set gauge to height of rear wheel brake support. Check cam pin height against this setting. Cam-pin should be equal or less this reading.

4) If cam pin height found to be more than height given above, raise brake shoe guide spring and file head of cam pin or replace pin with one of correct height.

To Low Cam Pin Correction—To help raise cam pin without distorting brake shoe support plate, use stand-C-clamp and Tool C-3248.

Dimpling of Brake Shoe For Pin Clearance—Support shoe on piece of pipe or socket wrench at point to be dimpled. Place ball end of a ball-peen hammer on web directly over pipe or socket. Using second ball-peen hammer, strike first hammer a few sharp blows, until enough metal is raised on reverse side of shoe web to reduce clearance. To increase clearance, strike shoe from reverse side so as to form a slight cavity in web directly above face of cam pin.

Grooving Brake Lining (See CAUTION below)—If above procedures do not correct squeaks (make certain that brake drum dampener spring are in place also), lining can be grooved to secure more perfect contact between lining and drum as follows: Clamp brake shoe in vise, scribe diagonal line on face of lining beginning at point 7/8" in from side at one end and 7/8" from opposite side at opposite end. Cut groove approximately .050" wide (use two fine hacksaw blades clamped together in holder) completely through lining to face of brake shoe.

►*CAUTION: Do not attempt to groove riveted lining or any of the edge-bonded, wire-backed, cycle-bonded linings.*

Slotting Brake Shoes (See CAUTION below)—If grooving does not correct squeaks, toe end of shoes can be slotted to depth of 1 3/8". Use hacksaw blade to cut web loose from shoe table (lining surface), cutting as close to table as possible.

►*CAUTION: Do not slot front brake shoes which have four 5/8" holes through the shoe table.*

DESCRIPTION: The "Safeguard" brake system consists of two-cylinder type hydraulic brake (front wheels), single double-acting cylinder type hydraulic brake (rear wheels):

Two-Cylinder (Front Wheel) Type—Consists of two independent single-acting brake cylinders mounted on the backing plate, each cylinder actuating one brake shoe. Each cylinder is mounted on the anchor pin of the other shoe (top cylinder mounted on rear shoe anchor pin and actuates forward shoe, bottom cylinder mounted on forward shoe anchor pin and actuates rear shoes). All shoes are "primary" or self-energizing type.

Single Cylinder (Rear Wheel) Type—Same as other "Lockheed Double Anchor Hydraulic" brake cylinders. Consists of single double-acting cylinder mounted at top of backing plate and actuating both brake shoes. Shoes are pivoted on anchors at bottom of backing plate.

►*CAUTION:* Before making any adjustment be sure anchor bolts are in correct position. Arrows must point **away** from the heels of shoes they control.

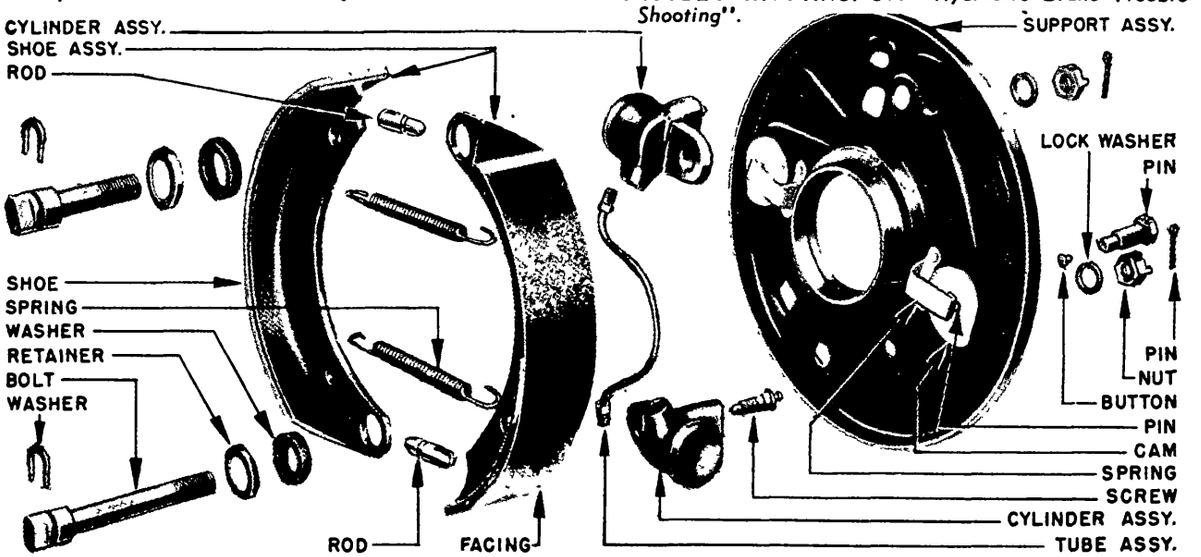
ADJUSTMENT: Before making adjustments, jack up all wheels, check brake pedal free travel (should be 1/8-1/4" to take up pushrod play) plus additional 5/8-3/4" (to close off master cylinder relief port) before brakes begin to be applied. Total pedal travel to apply brakes should be 1¾-2". If Minor Adjustment does not give correct pedal travel, or if relief port is cut off with less than ¾" pedal travel, check brake pedal free play

Brake Pedal Adjustment: Brake pedal must have 1/8-1/4" free travel. To adjust, loosen locknut on master cylinder end of pedal rod, turn large adjusting nut.

►*1955 PLYMOUTH NOTE:* Distance between brake pedal and pedal stop should be .015-.030", which will result in approximately 1/8" free play at pedal pad.

►*1955 POWER BRAKE NOTE:* Power Brake unit has built-in pedal return spring and a pedal return stop, and **requires no free play adjustment.**

Minor Wear Adjustment: Turn eccentric for each shoe out until shoe is solid against drum and wheel is locked, then back eccentric off until wheel is free.



Major (New Lining) Adjustment: Use adjusting gauge MT-19-K or feeler gauges and cutaway drum and adjust eccentric and anchor pin for each shoe to obtain .006" clearance at both toe and heel, for all models.

►*CAUTION:* After adjusting brakes on one wheel, do not use same gauge setting for brakes on another wheel. Gauge must be reset according to inside diameter of brake drum of **each** wheel.

Hand Brake Adjustment: Hand Brake is independent type mounted on driveshaft at rear of transmission. *See Car Model Pages and individual model Special Data Pages.*

BLEEDING BRAKE SYSTEM & OVERHAULING BRAKE UNITS: *See "Hydraulic Brake Servicing".*

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting".*

Chrysler Crown Imperial, C-53 (1951-52)

►CHANGES & CORRECTIONS

►*1952 BRAKE SUPPORT SPIDER PRODUCTION CHANGE*—New type brake support spider Chrysler Part **No. 1533209** (Left Front C-53 & 54); **No. 1533208** (Right Front C-53 & 54); **No. 1533211** (Left Rear C-54); **No. 1533210** (Right Rear C-54); **No. 1533215** (Left Rear C-53); **No. 1533214** (Right Rear C-53) replace type previously used. Early type spiders not available for service.

►*SUPPORT SPIDER REPLACEMENT CAUTION—New type spiders must be installed in pairs (both front wheels or both rear wheels).*

►**WHEEL CYLINDER PISTON CUP REPLACEMENT CAUTION**—Piston cups, Part No. 77526, bearing the letters "AA" or "DT" must be used. **Do not use cups bearing letters "BQ."**

►*BRAKE FLUID CAUTION—Do not use fluid from a pressure type filler or container that has been opened more than a few hours.*

DESCRIPTION

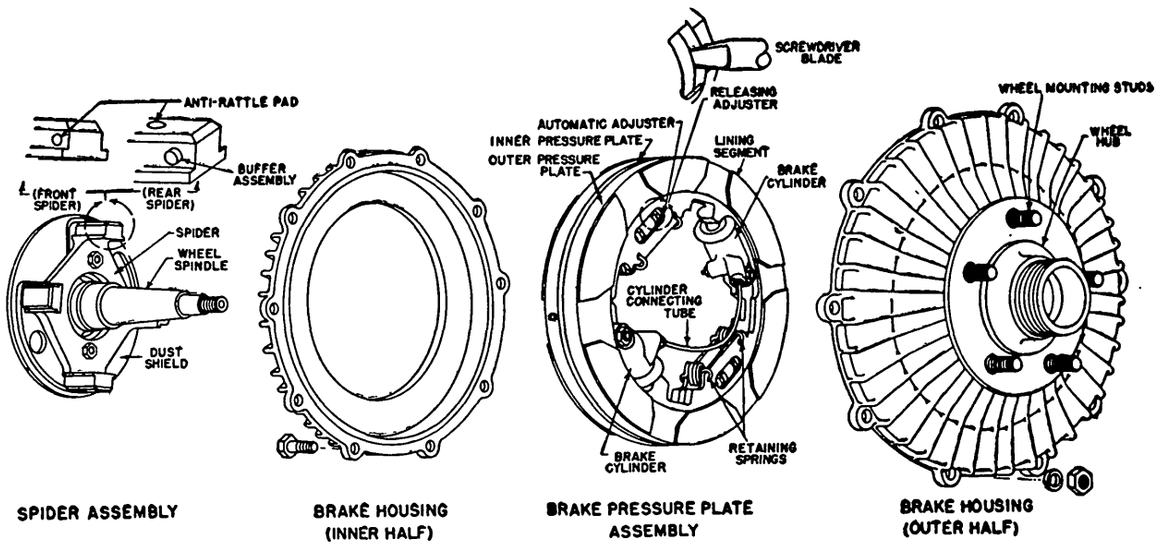
DESCRIPTION: The Chrysler Disc Brake is hydraulically operated, self-energizing. The brake assembly which is enclosed in a rotating housing, utilizes two lined pressure plates in the form of annular rings which move apart, contacting the inner surfaces of the rotating housing. The housing is split and is held together by 10 bolts around the outside. The plate assembly, which carries two hydraulic cylinders, is mounted on a spider attached to the front wheel spindle body and the rear brake spider on the rear axle housing flange. Automatic brake adjusters are built into the assembly. Brake lining segments are used, bonded to the outer surface of each pressure plate. Two hydraulic wheel cylinders move push rods operating against bosses on the outer plate to provide plate movement. 1¼" cylinders are used on the front brakes and 1" cylinders on the rear brakes.

OPERATION: When the outer plate is rotated with respect to the inner plate by movement of the wheel cylinder push rods, steel balls between the pressure plates are forced up on ramps located on the inside surfaces of the plates. The movement of the balls up the ramps forces the pressure plates apart and contact is made between the lining and the inner surfaces of the brake housing.

Self-Energization: The self-energization action is obtained by utilizing the friction force that tends to rotate the pressure plates in the direction of brake housing rotation when contact is established between the linings and the brake housing. When the brakes are applied, the outer plate is rotated forward by the action of the brake cylinder push rods and the plates are separated. During forward motion of the car, the inner plate is held rigid. Therefore, when the linings contact the housing, only the outer plate is free to move. The resulting additional forward movement of the outer plate, with respect to the inner plate, forces the balls higher on the ramps and consequently provides greater pressure contact between the plates and the housing. Thus some of the energy due to forward motion of the car is used to increase the braking effect. When the car is in reverse, the outer plate becomes the fixed plate on the rear wheels, and self-energization is provided by the movement of the inner plate when it contacts the housing. The front wheel brakes are not self-energizing when in reverse, as the inner plate is still the fixed plate.

Automatic Brake Adjusters: (NOTE—It is not necessary to remove automatic adjusters unless new plates are installed. However an inspection should be made to determine if correct adjuster pins are used and to see that pins are not scored or brinneled from the adjuster balls).

Adjuster Rod Identification: Rods that do not come within the following specifications should not be used.



(1)—Radial groove machined near one end of rod.

(2)—Purple dye on surface of rod.

(3)—Rod length is 2.445" to 2.446".

Adjusting Rod Inspection: Insert a small screwdriver between adjuster bushing and bracket to release adjuster balls. Move rod to one end. Wipe off pin surface and inspect, then move pin to other end and inspect. If pin is scored or brinneled, replace pin.

Wheel Brake Adjuster Operation—This self-adjusting mechanism automatically compensates for lining wear. Thus, the desired clearance is maintained at all times between the pressure plates and the brake housing, and full pedal effectiveness is provided. Two identical automatic adjusters are mounted opposite each other on the inside surface of each inner pressure plate. The adjusters are identical in operation for either front or rear brakes. Two lugs are provided on the inside surface of each outer pressure plate, and are placed so as to straddle the automatic adjusters. Refer to Illustr. Each self-adjusting unit is composed of a bracket (which is riveted to the inner pressure plate) with two guide flanges, a rod, a lubricating washer, 11 steel adjuster balls, an adjuster washer, a bushing and a sleeve. When the brakes are applied, the outer plate is rotated with respect to the inner plate and lug contacts the adjuster rod. Refer to Illust. If the brake linings are new, the linings contact the brake housing before the adjuster rod is pushed forward. However, if the linings have worn, the lug pushes the adjuster rod through the bracket guide flanges until the linings contact the brake housing, and the relative rotation of the outer plate stops. When the brakes are released, the brake return springs cause the outer plate to tend to return to its former position with respect to the inner plate. However, when lug on other end of rod contacts adjuster rod, the locking action provided by the automatic adjuster prevents the adjuster rod from being pushed back, and the outer plate cannot return completely to its former position. Because the difference between the length of the rod and the distance between the finished surfaces of the lugs has been calculated to provide the desired clearance between the linings and the housing when the brakes are released, proper clearance is maintained regardless of the wear on the linings.

CHRYSLER DISC BRAKE ASSY.

ADJUSTMENTS

ADJUSTMENT: Self-adjusters are used and no service adjustments are necessary.

Brake Pedal: ⅛-¼" free travel. Adjust by loosening locknut on master cylinder end of pedal rod and turning large adjusting nut.

Parking (Hand) Brake: Independent type. See Car Model pages for adjustment data.

C NTINUED N NEXT PAGE

CHRYSLER DISC BRAKE (WITH SPIDER) Cont.

OVERHAUL

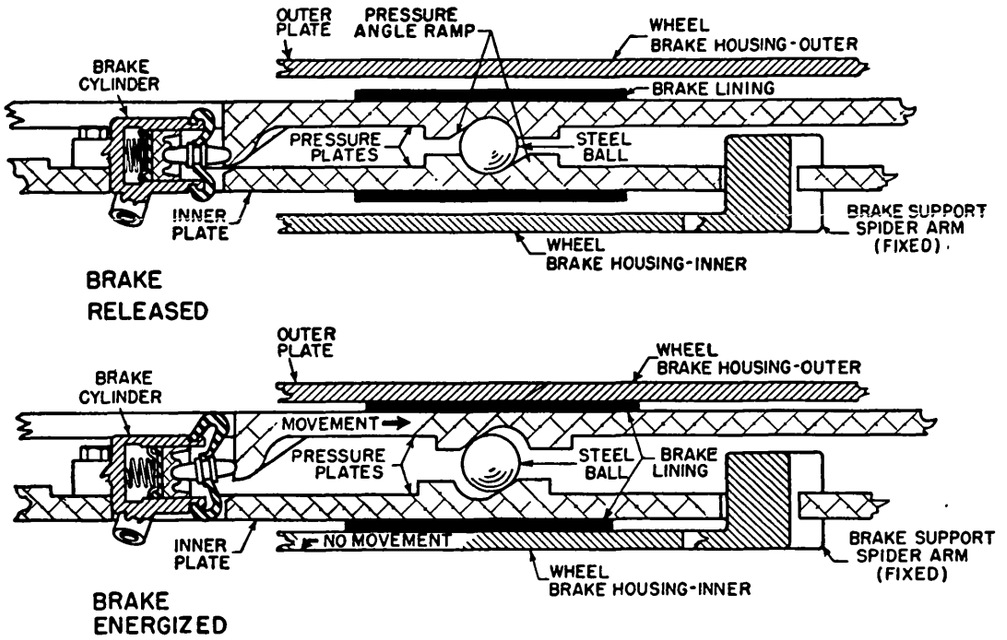
REPAIR DATA: ***CAUTION—None of the parts on four wheel disc brake assemblies are interchangeable. When more than one assembly is being serviced at one time, care should therefore be taken to keep the parts of each assembly separated from the others.***

Wheel Brak Cylinders: Front brake cylinders are 1¼" diameter and rear cylinders are 1" diameter. Two cylinders are used on each brake.

Bleeding Brakes: While bleeding brakes it is important to keep the master cylinder full of fluid. A long rubber hose must be used on bleeding screw while bleeding screw is open. Bleed only one cylinder at a time. Best results are obtained by bleeding all four lower cylinders first and then bleeding all four upper cylinders.

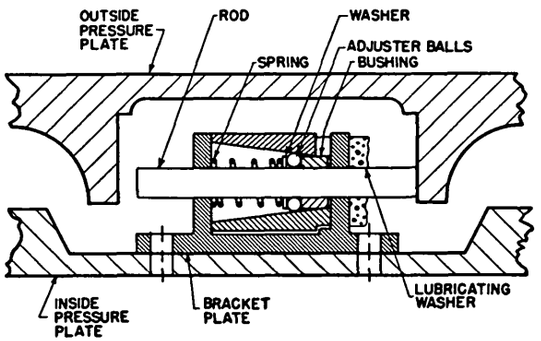
ADJUSTING BRAKES (After Bleeding or Overhaul): After bleeding or reassembly brake pedal will be very low. To build up pedal pressure and adjust pressure plates to housings, drive car forward very slowly, depressing and releasing brake pedal slowly as car moves forward. After pedal has built up to approximately ¾ of its full height, recheck fluid level in master cylinder. Drive car on road for at least five miles, applying brakes at intervals, until there is no pull to right or left when brakes are thoroughly warm and a severe brake application is made.

►**BRAKE MASTER CYLINDER NOTE**—The master cylinder must be assembled from the pushrod end —never from the plug end—otherwise damage will occur to valve seal ring. Be sure valve seal ring is in position before installing valve and spring. Note carefully that the valve seal seats directly on the end plug and valve part is held against seal by the return spring.



BRAKE LINING: To replace the lining it is necessary to remove the plate assembly. See disassembly procedure following. Segment type brake lining is used, bonded to the pressure plates.

►***CAUTION: When new linings have been installed, erratic operation may prevail for a few miles of operation. Car should be driven and brakes operated until normal brake applications result in smooth straight stops. This may take up to twenty-five or thirty miles of driving.***



BRAKE SUPPORT SPIDER INSPECTION & SERVICING: If brinneling or scoring is evident on the brake pressure plates caused by spider anti-rattle pads, it is advisable to replace the early type spider with the improved later type (See Production Change above).

Fitting Pressure Plate to New Type Spider: When installing the new type spider it is not necessary to replace the pressure plates unless the condition of the lining segments indicate replacement. If the same pressure plates are installed, the spider indexing surfaces of pressure plate must be free from brinneling or scoring. If these surfaces are not smooth they may be dressed with a strip of fine abrasive cloth backed with a flat file.

Fitting Pressure Plate to Early Type Spider: Examine the four spider indexing slots in inner pressure plate. Sides and outer surfaces of these slots must not be scored or show deep indentations made by anti-rattlers in spider. With spider mounted steering knuckle or axle housing, place inner pressure plate in its proper position on spider. While holding

PRESSURE PLATE ASSEMBLY RELEASED & ENERGIZED

AUTOMATIC ADJUSTER

pressure plate in position, move it back and forth on spider. There should be slight resistance to this movement and no binding of plate on spider. If binding is evident remove a slight amount of metal from the **pressure plate indexing slots**, not from spider legs. Use a strip of fine abrasive paper backed up with a flat file to smooth sides of indexing surfaces, and a half-round file for the slightly rounded surfaces. Never use a file alone as it will leave a rough surface. Apply a coating of chalk to outer surfaces of spider legs to check for high spots or place of binding. Anti-rattle pads should bear against indexing slots of pressure plate with a slight pressure. Reduce excessive pressure by dressing down anti-rattle pads with fine abrasive paper backed up with a flat file ***(CAUTION—Do not remove excessive metal from anti-rattle pads).*** Examine ball ramps and if light scoring is present, these may be lightly polished with a small piece of fine abrasive paper applied with the finger tip. If deep brinneling present, replace pressure plate. The removal of excessive metal at this point will cause brake to rattle in service.

Disassembly of the Front Disc Brake: Remove dampener spring and clips. Remove the ten bolts around brake housing. The inner and outer housings are matched sets. A cut-out is cast in each housing so that both halves can be mated to their original position. Remove dust cap and wheel bearing nut. Separate inner and outer housings by tapping lightly, at one of the attaching bolt hole flanges, with a fibre-nose hammer. When housings separate, remove outer wheel bearing. Pull off the hub and outer brake housing. Disconnect front brake hose from the tube at frame connection. The hose should be held down to drain fluid. Remove the brake tube dust grommet (2 metal screws) from the dust shield and slide the grommet off the brake tube. (On late C-47 and on all C-49 Town and Country and C-50 models, the dust grommet will not have to be removed from dust shield.) Cover open end of brake tube with absorbent cloth to prevent brake fluid leakage on brake parts. Remove brake pressure plate assembly. Place the assembly on a clean surface or cloth on the bench. Keep plates and lining clean.

Assembly of the Front Disc Brake: Install inner half of brake housing. Prior to installing pressure plate assembly, release both self-adjusters. Release automatic adjusters by inserting a thin shank screwdriver between the release sleeve in the automatic adjuster and the adjuster guide of each adjuster, and then twisting both screwdrivers. See Illustr.. The pressure plates will then snap back into fully released position. Install brake pressure plate as-

CONTINUED ON NEXT PAGE

CHRYSLER DISC BRAKE (WITH SPIDER) C nt.

sembly. Install brake tube dust grommet. Connect brake tube to frame connection. Install assembly of hub and outer brake housing. Inner and outer brake housing are matched and balanced as an assembly so that it is necessary to line up the mating cutout or marks on each housing. Install outer wheel bearing, washer, and nut. Adjust bearing, install cotter pin and replace dust cap. Install the ten housing bolts, lock washers and nuts. Install dampener spring and clips.

Disassembly of the Rear Disc Brake: Disassembly procedure for the rear brake is similar to the front brake procedure, except as follows: After removing the 10 housing bolts, remove the outer housing with a hub puller. Remove axle key to prevent scoring the oil seals. When the pressure plates are removed two buffer assemblies mounted in the brake spider will fall out.

Assembly of the Rear Disc Brake: Rear brake assembly procedure is similar to the front brake procedure except as follows: Before installing the spider, check the inside face of the seal assembly. It must be flush with the inside face of the spider. Wrap a piece of wax paper over axle shaft to cover key slot. This will prevent cutting the seal lip. Then install spider and seal assembly in correct position—aligning buffer loading pin holes in spider to correspond with holes in dust shield. Install inner half of brake housing. Prior to installing pressure plate assembly, release both self-adjusters. (See Assembly of the Front Disc Brake.) Insert the two buffer assemblies in spider anchors. **NOTE: Be sure lock groove in buffer is facing dust shield.** Using a pair of water pump pliers, hold buffer in compressed position, in spider leg, and while fully compressed insert lock pin (round stock 3/16" dia. by 1½" long with blunt ends) through hole in dust shield, so the buffer will remain in compressed position when pliers are released. Install brake pressure plate assembly. After brake pressure plate assembly is in position, remove buffer lock pins. Install brake tube dust grommet (C-47 only) and connect brake hose to the tube at axle housing connection. Place hub and outer brake housing assembly in position on axle shaft, and line up key way. Insert key and drive into position with fibre-tipped hammer.

Disassembly of Inner and Outer Pressure Plates: Release automatic adjusters. By inserting a thin shank screwdriver between the release sleeve in the automatic adjuster and the adjuster guide of each adjuster, and then twisting both screwdrivers, the pressure plates will snap back into fully released position. (See Illustr.) Remove the four pressure plate retaining springs. These coil springs perform the same function as the return spring in the shoe-type brake in that they pull the pressure plates together when hydraulic pressure is released and prevent the plates from maintaining friction contact with the brake housing. A "V" slot cut into one side of a screwdriver will greatly assist in spring removal. The discs can now be separated.

Assembly of Inner and Outer Pressure Plates: With the wheel cylinders and automatic adjusters properly installed on the inner pressure plate, place the six steel pressure expanding balls (7/8" dia.) in the six ramps. Place outer plate into position in inner plate. It will be necessary to cock the wheel cylinder push rods slightly when positioning the outer plate. Automatic adjuster rods must also be centered so that operating lugs on the outer plate will straddle the rods. Install the four pressure plate retaining springs.

Disassembly of Automatic Adjuster: (See Illustr.) The rod in the automatic adjuster will only move in one direction and can be pulled out by hand. The adjuster sleeve can then be removed by sliding the sleeve out from between the bracket guides. It is not necessary to remove the bracket from inner pressure plate.

►***CAUTION: Hold a finger over each end of the sleeve during removal so that steel balls, washers, etc. inside will not be lost.***

Assembly of Automatic Adjuster: To assemble the automatic adjuster, it will be necessary to make a dummy shaft out of round stock ¼" in diameter by ¾" long chamfered on one end to use in place of the adjuster rod which is installed later. Place adjuster sleeve (slotted end down) upright on finger and insert dummy shaft (chamfered end up) in sleeve. Place bushing over dummy shaft. NOTE: Dummy shaft and bushing can be held in proper positions by placing the large end of a common paper clip around the shaft at the slotted end of the adjuster sleeve. Install the eleven adjuster balls around dummy shaft. Tap lightly to position balls. Install adjuster washer on top of balls. Place the adjuster spring over the shaft above washer. Holding thumb over spring, carefully remove paper clip, holding dummy shaft. Continue to hold pressure on spring —compress sufficiently to slide sleeve into position on the bracket. NOTE: The sleeve is grooved and the bracket is stepped, so that installation can be made the right way only. Align sleeve assembly so that dummy shaft is in line with the holes in the bracket guides. Insert the adjuster rod into the stepped end of bracket and force dummy shaft out. Push the adjuster rod through the adjuster until adjuster is in the center of the rod. Install lubricating washer on adjuster rod at stepped end of adjuster bracket.

Buffer Assemblies: The buffers which are used on the rear brakes only, control the clocking motion of the outer pressure plate.

►***CAUTION: Buffer assemblies are calibrated units. If defective replace the complete buffer assembly. When intalling buffers in the spider arm be sure the lock groove in buffer faces the dust shield (backing plate).***

CHRYSLER DISC BRAKE (WITHOUT SPIDER)

Chrysler Crown Imperial C59, 66, 70 (1953-55)

►*1954 ADJUSTER ROD PRODUCTION & CLEARANCE CHANGE:* The automatic adjuster rod-to-outer pressure plate clearance has been increased from .005-.010" to .015-.020". The rod length is reduced from 2.445-2.446" to 2.435-2.436".

DESCRIPTION: The Chrysler Disc Brake is hydraulically operated, self-energizing. The brake assembly, enclosed in a rotating housing, utilizes two lined pressure plates in the form of annular rings which move apart, contacting the inner surfaces of the rotating housing, when brake application is made. The housing is split and held together by 10 bolts around the outside edge. The pressure plate assembly rests on a duster located at the bottom of each brake housing. Automatic brake adjusters are built into the assembly. Brake lining segments are used, bonded to the outer surface of each pressure plate. Two hydraulic cylinders, mounted on steering knuckle in front and on the rear axle flange, move push rods operating against bosses on the pressure plates.

OPERATION: When the outer plate is rotated with respect to inner plate through action of the wheel cylinder push rods, steel balls between the pressure plates are forced up on ramps located on the inside surfaces of the plates. The movement of the balls up the ramps forces the pressure plates apart and contact is made between the lining and the inner surfaces of the brake housing.

Wheel Brake Automatic Adjuster: The self-adjusting mechanism automatically compensates for lining wear. Desired clearance is maintained, at all times, between pressure plates and brake housing. Two identical automatic adjusters are mounted, one on each plate, operating at 180° to each other, and are identical in operation for either front or rear brakes. Two lugs are provided on each of the two pressure plates, placed to straddle automatic adjusters. Each self-adjusting unit comprises a bracket (integral to the individual pressure plate) with two guide flanges, rod, lubricating washer, 11 steel adjuster balls, adjuster washer, bushing and sleeve. When brakes are applied, outer plate is rotated with respect to inner plate and lug contacts adjuster rod. If brake linings are new, linings contact housing before rod is pushed forward. If linings are worn, lug pushes adjuster rod through bracket guide flanges until linings contact brake housing and relative rotation of outer plate stops. When brakes are released, brake return springs cause outer plate to tend to return to former position. When lug on opposite end of rod comes into contact with the rod, the locking action (provided by the automatic adjuster) prevents adjuster rod from being pushed back, and outer plate cannot return completely to former position. Because difference between length of rod and distance between finished surfaces of lugs has been calculated to provide desired clearance between linings and housing when brakes are released, proper clearance is maintained regardless of wear on linings.

ADJUSTMENT: Self-adjusters used and no service adjustment to compensate for lining wear required during useful life of linings. Manufacturer recommends that plate assemblies be switched from front to rear every 15,000 miles to obtain maximum brake lining life.

Brake Pedal: ⅛-¼" free travel. Adjust by loosening locknut on master cylinder end of pedal rod and turning large adjusting nut.

Parking (Hand) Brake: Independent, internal expanding type. *See Car Model pages for adjustment data.*

REPAIR DATA: ***CAUTION—Inner and outer housings are balanced as an assembly and should be assembled accordingly. Further, do not install left pressure plates or wheel cylinders on right side or vice versa.***

Wheel Brake Cylinders: Front brake cylinders are 1¼" diameter and rear cylinders are 1" diameter. ***NOTE—Because there is no direct connection between pressure plate and wheel cylinders, brake assemblies can be removed as a unit from car without opening housings or disrupting hydraulic system.*** Normal inspection or replacement of front brake cylinder parts does not require removal of cylinder from steering knuckle.

CONTINUED N NEXT PAGE

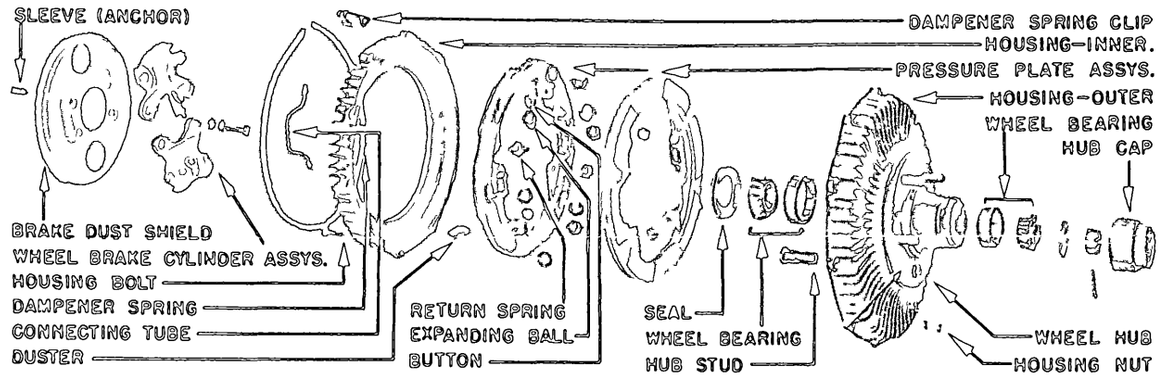
CHRYSLER DISC BRAKE (WITHOUT SPIDER) Cont.

Bleeding Brakes: *CAUTION—Do not use fluid from pressure type filler or a container that has been open more than a few hours.* Connect hoses at each wheel position. Fill master cylinder with a bottle type filler with fluid from newly opened, sealed container. Bleed lower cylinder on each wheel first—do by hand, not with pressure bleeder—then refill master cylinder reservoir after bleeding each cylinder. After bleeding all four lower wheel cylinders, bleed four upper cylinders.

▷*CAUTION—A short section of bleeder hose should be placed over bleeder valve before opening bleeder. If not done, it is possible for fluid to seep inside housings, contaminating linings.* Bleed only one cylinder at a time. Be very sure all air is expelled from brake lines and wheel cylinders.

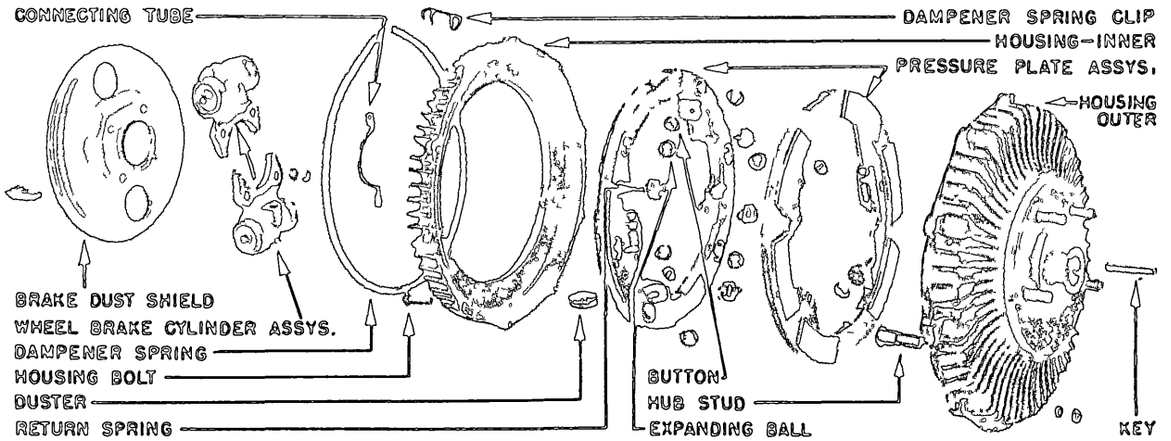
▷*CAUTION—After brakes are thoroughly bled, brake pedal will be very low. Drive car forward very slowly depressing and releasing brake pedal slowly as car moves forward. After pedal has built up to approximately ¾ of its full height recheck fluid level in master cylinder. Car should then be driven five miles applying brakes at intervals. There should be no brake dive or pulling to one side when brakes are applied.*

Brake Liming: Molded asbestos, segment type lining used, Cyclebonded. Thickness 5/32". Clearance between lining and housing—Self-adjusting.



▷*CAUTION—With new linings, erratic operation may result for a few miles of operation. Normal brake operation should occur after not more than 25 or 30 miles of driving.*

DISASSEMBLY: *NOTE—Brake assemblies can be removed from car as a unit without opening housings or disrupting hydraulic system.*



Front Disc Brake: Remove hub cap, cotter key spindle nut, then complete brake assembly from steering knuckle. Transfer assembly to clean bench with assembly resting on outer hub section. Remove damper spring and clips, then housing attaching bolts. Check to see that there are cast cut-outs in each housing (these cut-outs must be matched on reassembly). If no cut-outs, mark. Separate inner and outer housings by tapping lightly, at one of the attaching bolt hole flanges, with fibrenose hammer. Remove pressure plate assemblies *(do not lose duster at bottom of each housing).* Place brake pressure plate assembly on clean surface or cloth (to avoid contamination of lining segments).

Rear Disc Brake: Remove cotter pin, axle nut and washer. Install Wheel Puller C-844, remove brake housing, pressure plate and hub assembly. Remove axle shaft key, dampener spring and clips, then remove housing attaching bolts (Check to see that there are cast cut-outs in each housing. These cut-outs must be matched on reassembly. If no cut-outs, mark). Separate inner and outer housings by tapping lightly, at one of attaching bolt hole flanges, with fibrenose hammer Remove outer brake housing pressure plate and hub assembly *(do not lose duster at bottom of each housing).* Place brake pressure plate assembly on clean surface or cloth (to avoid contamination of lining segments).

Inner & Outer Pressure Plates: Release automatic adjusters. (By inserting a thin shank screwdriver between release sleeve in automatic adjuster and adjuster guide, then twisting screwdriver, pressure plates will snap back into fully released position). Remove four pressure plate retaining springs ("V" slot cut into one side of a screwdriver will facilitate removal). Separate discs.

FRONT BRAKE

REAR BRAKE

CHRYSLER DISC BRAKE ASSY. (WITHOUT SPIDER)

Automatic Adjuster: Push or pull rod out by hand (moves in one direction only). Slide sleeve out from between pressure plate lugs. *CAUTION—Hold finger over each end of sleeve during removal so contents are not lost.*

INSPECTION & CLEANING: Proceed as follows:

Wheel Cylinders: Examine bores and pistons for score marks or pits. Replace if necessary. Replace piston cups with new ones. *CAUTION—Only front wheel cylinder piston cups Part No. 77526 bearing letters "AA" or "DT" should be used. Do not use cups bearing letters "BQ".* Reassemble wheel cylinders using new dust boots.

Automatic Self-Adjusters: *NOTE—It is not necessary to remove adjusters unless new pressure plates to be installed.* Inspect adjuster rods to determine if correct rods are present and for scoring or brinelling from adjuster balls.

Adjuster Rod Identification—Rod has radial groove machined at one end. Length of rod is 2.445-2.446" (1953), 2.435-2.436" (1954-55).

Scoring & Brinelling Inspection—Insert small screwdriver between adjuster bushing and bracket to release adjuster balls. Move rod to one end. Wipe off pin surface and inspect. Move pin to opposite extreme to inspect other end. Pin should be free of scoring or brinelling. *Do not lubricate automatic adjusters.*

Brake Housings: Inspect for cracks. If found, replace. Light radial marks on surface of housing may be polished out with fine emery cloth. Similarly with bluish heat spots. *NOTE—Do not mate 40-fin housing with 60-fin housing on opposite side of car.*

Pressure Plate Expanding Balls: Should be clean and free of flat spots, rust or nicks. Dull coating on balls is not reason for rejection. This is protective coating and does not affect operation. Rusted balls may be cleaned by placing in cloth bag partially filled with sand and shaking vigorously.

Master Cylinder: Remove from car. Clean and inspect for pits and scores. Replace if found. Reassemble using new valve and cups. *CAUTION—Assemble from*

CONTINUED ON NEXT PAGE

CHRYSLER DISC BRAKE (WITHOUT SPIDER) C nt.

push rod end to prevent damage to valve seal ring. Be sure valve seal ring in position before installing valve and spring. Note carefully that valve seal, Part No. 1318447 seats directly on the end plug and the valve, Part No. 1318446, is held against this seal by return spring.

REASSEMBLY: ***NOTE—Inner and outer housings are balanced as an assembly and should be assembled accordingly. Do not install left pressure plates or wheel cylinders on right side or vice versa.***

Disc Brake: Release both automatic adjusters, install brake pressure plate assembly in outer housing half, place duster in "down" position at bottom of pressure plate. Install inner housing and line up aligning marks (cut-outs) in each housing, tighten 10 attaching bolts, install dampener spring and clips. Apply pressure on push rods of wheel cylinders to facilitate pressure plate installation. ***NOTE—It may be necessary to open bleeder screws to allow pistons to retract. Manufacturer recommends that bleeder screws be tightened with pistons retracted. This holds pistons in position desired until pressure plates installed.*** With pressure plates in down position and duster in position, proceed as follows:

Front Brake—Position housing pressure plate and hub assembly, then slip complete assembly over steering knuckle and wheel cylinders making sure plates are piloted properly over wheel cylinders to avoid damaging or dislocating boots Install outer bearing, spacer washer, nut, and adjust wheel bearings. Install cotter key, hub cap, and wheel assembly.

Rear Brake—Mount housing and pressure plate assembly to axle shaft making sure that plates are piloted properly over wheel cylinders to avoid damaging or dislocating boots. Position key-way, install key, washer and nut. Tighten axle shaft nut to 140 ft. lbs. minimum, then install cotter key, tire, and wheel assembly.

Inner and Outer Pressure Plates: With automatic adjuster properly installed on each of pressure plates, place the six steel pressure expanding balls (7/8" diameter) in the six ramps. Place outer plate in position on inner plate. Automatic adjuster rods must also be centered so that operating lugs on the matching plate will straddle rods. Install four pressure plate retaining springs.

Automatic Adjuster: Make dummy shaft out of round stock 1/4" in diameter and 3/4" long, chamfered on one end. Place adjuster sleeve (slotted end down) upright on finger and insert dummy shaft (chamfered end up) in sleeve. Position bushing over dummy shaft. Hold shaft and bushing in position with large end of common paper clip. Install 11 adjuster balls. Tap lightly to position balls, install adjuster washer, position adjuster spring in sleeve. Holding thumb over spring, carefully remove paper clip. Continue to hold pressure on spring-compress sufficiently to slide sleeve into position on bracket. NOTE—Sleeve is grooved and pressure plate stepped so that installation can only be made right way. Align sleeve assembly so that dummy shaft is in line with holes in pressure plate. Insert adjuster rod in pressure plate hole and force dummy shaft out. Center adjuster rod as nearly as possible. Install lubricating washer on adjuster rod at stepped end of adjuster bracket.

HAWLEY MECHANICAL TWO-SHOE TYPE

Crosley, Model CC (1947-48)

TYPE: Two-shoe, four-wheel, mechanically operated (cable) type.

DESCRIPTION & OPERATION: Wheel Brakes—Two shoes per wheel, anchored at adjusting screw end and operated by cam at opposite end. Shoes are held against adjusting screw and cam by coiled springs hooked between the shoes (lighter spring at adjusting screw end, heavier spring at cam end of shoes).

Linkage: Wheel brakes operated by cables linked between cam operating levers on backing plates and levers on main cross-shaft on frame. Cables are enclosed in conduits at wheel ends and have adjusting clevises at cross-shaft ends.

Hand Brake: Parking brake handle on floor board in front of driver's seat linked directly to lever on main cross-shaft and applies all four service brakes. No adjustment is required.

ADJUSTMENT: Jack up all four wheels securely. Remove cotter pins and clevis pins from all four wheel cables at brake cross-shaft. Adjust as follows:

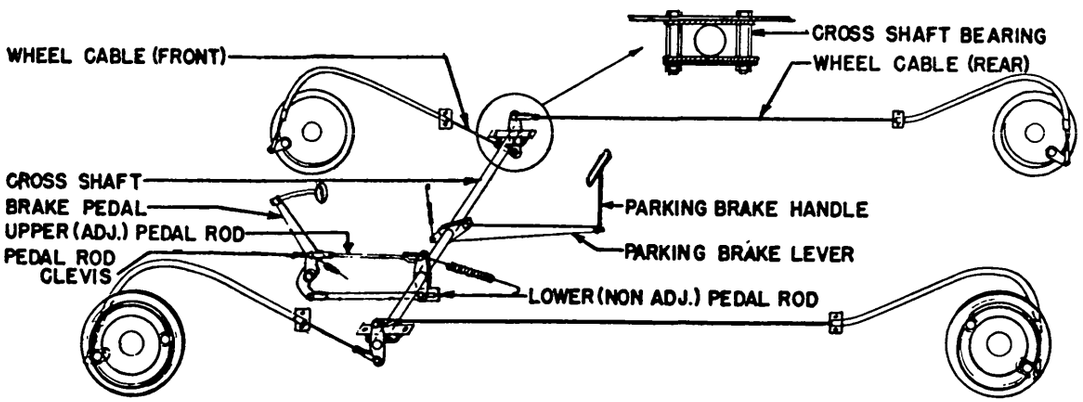
Brake Shoe Adjustment: Jack up all wheels, disconnect wheel cables by removing cotter pins and clevis pins from levers at each end of cross-shaft. Install cross-shaft spacer (see Spacer Note below) on each side of cross-shaft bearing at each end of shaft. Check brake pedal linkage adjustment and make certain that both upper and lower rods act on cross-shaft simultaneously. At each wheel, loosen adjusting screw locknut on backing plate, tighten adjusting screw (turn screw counter-clockwise) until brakes begin to drag, then back off screw (approximately ¼ turn) until wheel turns freely, tighten locknut.

Cross-shaft Spacer Note—Spacers consist of piece of bar stock, 3/16" thick, ½" wide, 3" long, with 30° bend at center (included angle 150°).

Brake Linkage Adjustment: After adjusting brake shoes (above), depress brake pedal 1" and hold it in this position by pulling hand brake lever "on". Adjust each wheel cable by loosening clevis locknut and turning clevis until wheel brake drags slightly when cable connected to cross-shaft lever. With all cables adjusted and connected, pull hand lever "on" for considerable brake drag, check all wheels for equal drag. Equalize by readjusting cables. Push brake pedal down hard, hold in this position by pulling hand lever "on". Check each wheel to see that all wheels are locked and that reserve cable travel (distance from clevis to brake cable clamp on backing plate) is ½" minimum. **Remove spacers from cross-shaft bearings.**

Hand Brake: No adjustment required.

SERVICING: Brake Lining Replacement—Manufacturer recommends that factory replacement shoes (with lining installed) be used. Lining is molded type and is ground concentrically after installation on shoes. CAUTION—Keep paired brake shoes together.



Brake Shoe Installation—Install heavier retracting spring on cam end of brake shoes with spring hooks inward toward backing plate, install lighter spring on adjusting screw end of brake shoes with spring hooks outward or away from backing plate.

CAUTION—Replacement brake shoes are ground in pairs and paired shoes should be kept together and installed on same wheel.

Cross-shaft Installation: Bearings must be assembled on cross-shaft when shaft installed on car. Insert bolts with head on inside of frame, install flat fabric bearing on bolts next to frame, place spacer on each bolt, install second flat fabric bearing, bearing plate, lockwashers and bolt nuts. Before tightening nuts, install cross-shaft spacer at each cross-shaft bearing (see Cross-shaft Spacer Note under Brake Shoe Adjustment above), to center the shaft, then tighten bolt nuts. Adjust the brakes.

►***CAUTION—See that cross-shaft remains centered in the slotted bearings while connecting cables and adjusting brakes.***

Brake Pedal Linkage Adjustment: With the brake pedal against the floor board stop, rotate the cross-shaft until lower bracket pin is against the front end of the slot in the lower (non-adjustable) brake pedal rod. Hold cross-shaft in this position, adjust clevis on forward end of upper brake pedal rod until upper bracket pin on cross-shaft is against the rear end of slot in upper pedal rod. This setting does not change in service and no adjustment is required when brakes are adjusted.

HAWLEY MECHANICAL BRAKE SYSTEM

GOODYEAR-HAWLEY HYDRA-DISC HYDRAULIC

Crosley, Model CD & Hotshot (1949-50)

►**WHEEL HUB REMOVAL CAUTION**—Wheel brake unit must be disassembled before wheel hub and brake disc can be removed. See Wheel Brake disassembly data below.

DESCRIPTION: Goodyear-Hawley hydraulic disc have new type wheel brakes as follows:

Wheel Brakes: Consists of an inboard housing containing the single acting hydraulic cylinder with circular lining mounted directly on the end of the hydraulic cylinder piston, and an outboard housing on which a second circular lining is mounted directly. These housings are bolted together by tie bolts and mounted on the dust cover so that they straddle the brake disc which is integral with the wheel hub. In operation, the piston moves out to bring the lining in contact with the disc and the reaction in the opposite direction causes the entire assembly to move inward so that the outer lining is likewise brought into contact with the drum and the disc is gripped between the two linings. When brakes are released, return springs return the piston and entire assembly to their original positions.

Hand Brake: Consists of a cam lever in each rear wheel brake which applies the brakes mechanically (operation is similar to hydraulic actuation). These levers are linked to the hand lever at the driver's seat by a rod and cable linkage.

Master Cylinder: Conventional type. Similar to design used with other hydraulic brake systems.

ADJUSTMENT: Wheel Brakes. Jack up all four wheels, loosen locknut on compensating screw on inner housing (CAUTION—locknut has left-hand threads). Turn compensating screw clockwise until wheel is locked, then back off compensating screw ¼ turn. Tighten locknut (CAUTION—see that compensating screw does not turn while tightening locknut). Adjust all four wheels in this manner.

Hand (Parking) Brake Adjustment: Should not require adjustment (automatically taken up when wheel brakes adjusted). If hand lever travel excessive, tighten clevis at rear end of hand lever rod or tighten clevis at left wheel end of wheel cable.

►*CAUTION*—Do not move parking brake cam lever (in rear wheel brakes) away from released position when adjusting hand brake cable.

Brak Pedal Adjustment: Pedal should have ¼" free travel in released position with master cylinder pushrod against its stop. Adjust by loosening locknut and turning pushrod.

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting" for complete data.*

BLEEDING BRAKE SYSTEM: Loosen brake hose at wheel unit ½ turn (CAUTION—do not attempt to disconnect hose without removing brake unit). Tighten hose after bleeding operation completed.

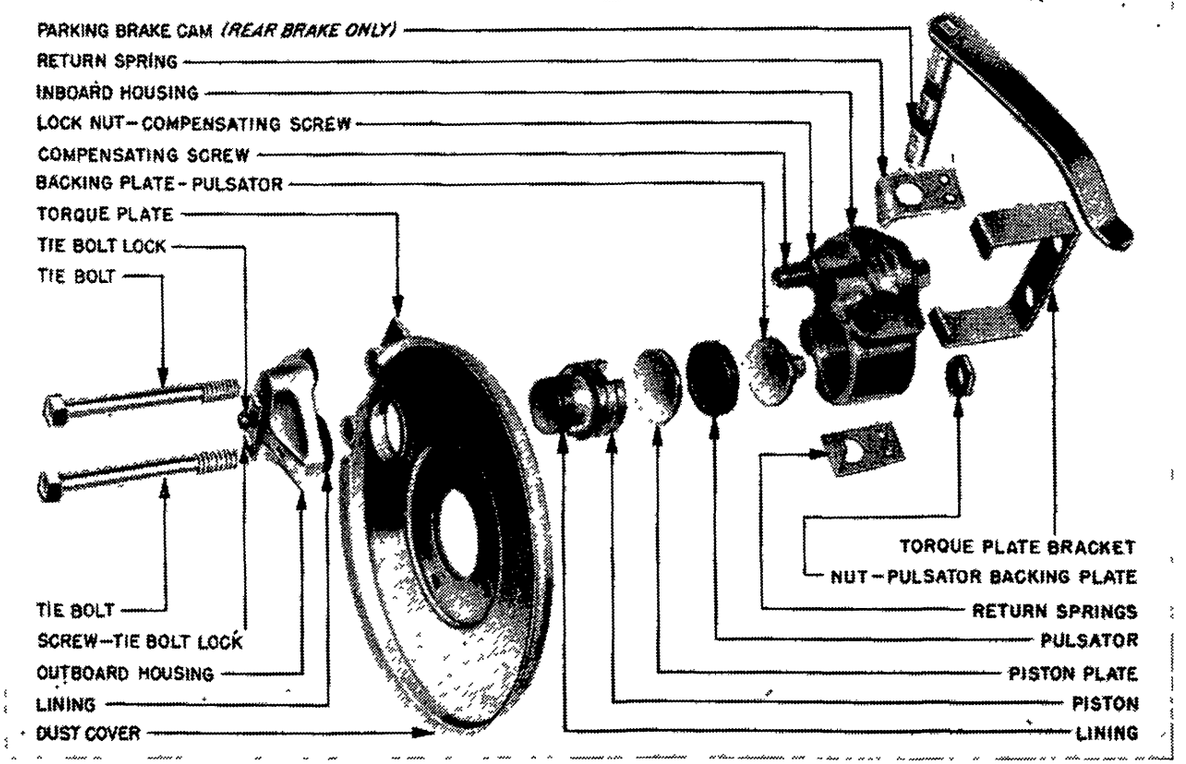
See "Hydraulic Brake Servicing" for complete bleeding instructions.

►*CAUTION*—Use only Lockheed #21 Brake Fluid.

REMOVAL & INSTALLATION OF WHEEL UNIT: *Necessary for servicing of unit and for wheel hub removal.*

Removal: Loosen brake hose at wheel cylinder (CAUTION—do not attempt to remove hose). Take out tie bolt lockplate screw (Phillips head screw on outer housing), remove lockplate, unscrew both tie bolts, lift off outer housing. Remove four Phillips head screws in torque plate, slide inner housing assembly out. Hold brake hose and unscrew brake unit from hose.

Installation: Screw inner housing unit on brake hose snugly. Position unit on mounting bracket and install four torque plate screws. Install outer housing, screw both tie bolts in finger-tight (see Compensating Screw Setting below) and back screws off to nearest flat which will allow lockplate to be installed, install tie bolt lockplate and lockplate screw. Bleed brakes, then tighten brake hose, and adjust brakes.



►**Compensating Screw Setting**—Compensating screw must contact outer housing with approximately 1/16" clearance between lining and disc. Adjust by turning compensating screw before tie bolts are started in threads.

DISASSEMBLY & REASSEMBLY OF WHEEL UNIT: *For replacement of Pulsator or other service operations.*

Front Wheel Unit: With wheel unit removed from car, remove return springs by taking out attaching screws, remove piston. Insert a screw in the threaded hole on the side of the cylinder, remove lockring from groove in cylinder. Remove nut on back of inner housing, push piston plate, pulsator, and pulsator backing plate out of cylinder. Remove pulsator from backing plate and wash all parts in alcohol. When reassembling, place new pulsator on backing plate and install these parts in cylinder (CAUTION—Keep oil and grease off pulsator and make certain it does not catch in lockring groove and peel back over backing plate), tighten backing plate nut on housing loosely. Install piston plate and lockring, position lockring gap approximately 1" from threaded hole in cylinder. Install piston and return springs, then tighten backing plate nut securely.

Rear Wheel Unit: With wheel unit removed from car, remove return springs by taking out attaching screws, remove piston. Lift out parking brake cam and lever assembly. Remove nut on back of inner housing, push piston plate, pulsator, and backing plate out of cylinder. Remove pulsator from backing plate and wash all parts in alcohol. When reassembling, place new pulsator on backing plate, install in cylinder (CAUTION—Keep oil and grease off pulsator), tighten backing plate nut on housing loosely. Install piston plate, insert parking brake cam and lever (see illustration for correct position), install piston making certain that groove engages parking brake cam. Install return springs, then tighten backing plate nut securely.

RELINING BRAKES: Lining is riveted to piston and on outer housing. When installing new lining, make certain that lining is seated on lockpin.

O DYEAR-HAWLEY HYDRA-DISC BRAKE (REAR BRAKE SHOWN—
FR NT BRAKE SAME EXCEPT PARKING BRAKE CAM MITTED)

CHEVROLET (OWN) HYDRAULIC

Passenger Cars, All Models (1937-50)
Comm'l & Trucks, All Models (1937-50)
Trucks, ¾ & 1 Ton (1951-52)
Trucks, 1½ & 2 Ton (1951-52) Front Only

►*1½ & 2 Ton NOTE—See "Chevrolet Twinplex" for rear brakes on these trucks.*

►CHANGES, CAUTIONS, CORRECTIONS

►**TRUCK BRAKE BOOSTER NOTE:** Hydrovac Power Unit Std. or Optl. on 1, 1½ & 2 Ton Trucks. *See "Hydrovac Power Unit" for complete data.*

►*CAUTION*—On trucks with Hydrovac, special brake system bleeding procedure is required. See special bleeding instructions under "Servicing" below.

►**1½ & 2 TON BRAKE CABLE CHANGE (1939-48 for Increased Clearance between Tires and Cable):** Approximately 1" additional clearance between tires and brake cables can be secured by installation of following parts:

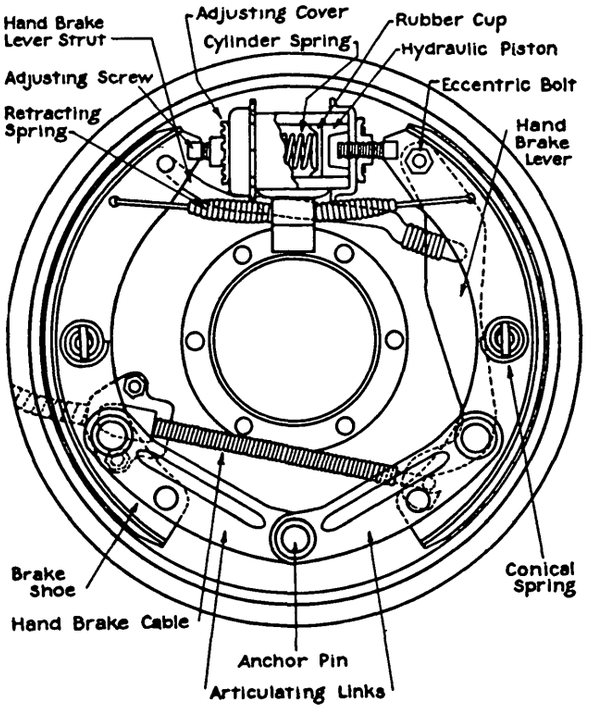
Hand Brake Cable Axle Bracket—Brackets approximately 1" longer than original type furnished under Part No. 3686657 (R. H.), 3686658 (L. H.) for all 1937-47 Trucks.

Hand Brake Cable & Clamp Assembly—New design assembly which holds cable inward after it leaves cable frame bracket furnished for all models as follows: 1939-46 Utility Models—3651403 (R. H.), 3651404 (L. H.). 1947-48 Half-Ton Comm'l—3686522. 1947-48 ¾ Ton Comm'l—3676305. 1947-48 One-Ton Comm'l—3684247. 1947-48 1½ & 2 Ton (137" & 161" WB)—3686686. 1947-48 2 Ton C-O-E (110" WB)—3686727. 1947-48 1½ & 2 Ton School Bus & 2 Ton C-O-E (134" & 158" WB)—3686685.

►**BRAKE SHOE INSTALLATION CHANGE (To Correct Erratic Brake Action When Wet Complaints):** Brake lining on front wheels must be Inlite 599849 or Marshall Eclipse 3682131 (see identification data below). Manhattan 475518 lining (also furnished in Pkg. No. 603872) must not be used on front wheels.

NOTE—All service packages with Manhattan lining now stamped "Use on Rear Brakes only."

Lining Identification—Inlite lining has blue identification on side, Marshall Eclipse has orange identification mark. Manhattan lining not marked but packages will be marked as above.



►*CAUTION—Manhattan lining must be used on rear wheels only. Inlite & Marshall Eclipse lining can be used on either front or rear brakes.*

DESCRIPTION

DESCRIPTION & OPERATION: Wheel Brakes. Two shoes per wheel similar to previous design in that shoes are mounted on articulating links at anchor pin end with upper end bearing directly on wheel cylinder piston adjusting screws. Rigid type hydraulic wheel cylinder mounted on backing plate between shoes. Shoes are forced out in contact with drum by piston movement when fluid displaced from master cylinder by pedal application flows through lines to wheel cylinder. Articulating links result in uniform shoe contact with drum and only one adjustment (at piston) provided. Shoes returned to off position when pedal released by single retracting spring linked between shoes.

Adjustment Note (1940 On). Slots provided in front wheel backing plates (closed by snap covers) on all models so that brakes can be adjusted without removing wheels.

Hand Brake:—Hand lever applies rear wheel service shoes through cable actuated lever pivoted on one shoe and linked to other shoe by strut (passenger cars) or lever and link (1½ ton truck).

REAR BRAKE ASSY. (FRONT SAME EXCEPT HAND BRAKE LINKAGE OMITTED)

Hand Brake (Passenger Cars 1940 On):—Cars have idler lever mounted on bracket welded to second cross-member (at rear of transmission) and linked to each rear wheel by cable with adjustment on each cable at idler lever end (see Adjustment data below).

Parking Brake (1947-50 ½ & ¾ Ton Trucks)—Rear wheel brakes are applied by a foot-operated pedal and released by a button under the instrument panel. See Parking Brake adjustment data below.

Master Cylinder:—Compensating type similar in design to type used on other brake systems. *See "Hydraulic Brake Servicing" for complete data.*

BLEEDING BRAKE SYSTEM: Required when lines disconnected, to remove wrong type fluid if used in system, or to remove air from lines caused by allowing master cylinder supply tank to become dry or by disconnecting lines.

All Pass. Cars (and Trucks without Hydrovac): *See "Hydraulic Brake Servicing" for complete data.*

►**Trucks with Hydrovac Brak System**—When bleeding entire brake system, Hydrovac unit must first be bled at tw points before bleeding the lines and wheel cylinders. Bleed the entire system exactly as detailed below (CAUTION—Engine must not be running and there must not be any vacuum in the Hydrovac system while bleeding these brakes).

Hydrovac P int #1—Remove bleeder valve screw on side of control valve housing on Hydrovac endplate, attach bleeder hose and submerge end of hose in brake fluid in a clean drain jar. Fill brake master cylinder reservoir with fluid, open bleeder valve ½-¾ turn, depress brake pedal slowly by hand, close bleeder valve before releasing pedal. Repeat these operations until fluid flows from the hose in a solid stream without bubbles, then close bleeder valve, remove hose, install valve screw.

Hydrovac Point #2—Attach bleeder hose at bleeder valve on side of Hydrovac unit outlet fitting (point at which brake lines to wheels connected). Bleed system at this point in exactly same manner as detailed for Point #1 (above).

Wheel Cylinders—After bleeding Hydrovac unit, proceed to bleed lines and wheel cylinders at each wheel in the usual manner.

BRAKE PEDAL ADJUSTMENT

Pedal Clearance Note: Clearance between pedal and underside of toeboard must be correct to insure master cylinder piston being back against its stop for correct compensating action when brakes released (clearance between edge of master cylinder piston primary cup and center of compensating port must be .035" minimum).

Adjustment—Adjust each model as follows:

Passenger Cars (With mechanically operated St p Light Switch). Clearance between upper face of pedal and first toe-board re-inforcing rib below pedal rod must be 7/16". Adjust in same manner as previous models by loosening locknut on eccentric pedal bolt and turning bolt. Tighten locknut to 20-25 ft. lbs. after adjusting.

►*CAUTION*—If correct 7/16" clearance cannot be secured by turning eccentric bolt, adjust by installing shims under front or rear master cylinder mounting bolts.

Trucks (1937-47). Loosen clevis locknut on rear end of master cylinder pushrod, turn pushrod until correct clearance of ¼" is secured between pedal and underside of toeboard with pedal released, tighten locknut after adjusting.

Trucks (1947-52). Clearance between top of pedal arm and underside of depression in toe pan at pedal must be 13/16" with pedal released and master cylinder piston against its stop. To adjust, loosen locknut at pushrod clevis, turn pushrod (knurled section provided on rod for this purpose), tighten locknut after adjusting.

BRAKE SHOE ADJUSTMENT

►*CAUTION*—Before adjusting, jack up all wheels, disconnect hand brake cables at idler lever on cross-member (Pass. Cars, Half-Ton, & Forward Control trucks), or at cross-shaft idler levers (other trucks). Remove adjusting cover on backing plate at each end of wheel cylinder (not necessary for rear wheels on 1½ & 2 Ton or 1 Ton after 1947). Adjust each wheel as directed below. If brake drums have been removed previously, apply brakes firmly to align articulating pins before adjusting.

CAUTION—Hand brake cables or rods must be disconnected to eliminate possibility of shoes being held on which would result in incorrect adjustment.

CONTINUED ON NEXT PAGE

CHEVROLET (OWN) HYDRAULIC (Continued)

Pass. Cars & Half-Ton (Front & Rear Wheels): Insert point of screwdriver in slot on backing plate at each end of wheel cylinder so as to engage notched adjusting covers on cylinder, turn adjusting covers until shoe has slight drag on drum, then back cover off exactly 4 notches (Pass. Cars & 1939-47 Half-Ton), 5 notches (Half-Ton beginning 1948) for correct shoe clearance. Adjust all wheels in this manner, then adjust parking brake and check brake pedal clearance.

Trucks (except Half-Ton): *CAUTION—Front and rear wheels adjusted differently as follows:*

Front Wheels (All Trucks)—Insert point of screwdriver in slot on backing plate at each end of wheel cylinder so as to engage notched adjusting covers on cylinder (adjusting cover at each of cylinder controls one shoe), turn adjusting covers until shoe has slight drag on drum, then back cover off exactly 5 notches for correct shoe clearance. Adjust both wheels in this manner.

Rear Wheels (All ¾ Ton & 1941-47 1 Ton)—Adjust in same manner as front wheels (above), backing cover off 5 notches for correct shoe clearance.

Rear Wheels (1948-52 1 Ton, 1939-50 1½ & 2 Ton). Use an open-end wrench to turn the hexagonal headed pinion shaft on brake backing plate (shaft turns adjusting covers through gear engagement). Turn pinion shaft clockwise (looking out toward backing plate) until shoe drags slightly, then back pinion shaft off 2/3 turn (four sides of hexagonal head) for correct running clearance. Adjust parking brake (see below) and check brake pedal clearance.

HAND BRAKE ADJUSTMENT

Parking Brake Adjustment Caution: Different types of linkages used. Adjust each model as follows:

Passenger Cars (All Models): Place the hand lever in fully released position. Loosen both checknuts on each wheel cable at idler lever on frame cross-member (forward end of cables), pull cables forward out of conduit until definite stop is felt, hold cable in this position and tighten both checknuts on each cable so that cable is locked to idler lever toggle. Make certain that rear wheels are free.

Trucks (1939-47): Place hand lever in fully released position. Pull wheel cable end fitting (at front of rear frame cross-member) forward until a definite stop is felt, hold cable in this position, turn nut on forward rod down until it contacts (turn by hand only, do not use wrench), lock cable by turning rear nut up securely. Check equalization and make any necessary re-adjustment by loosening wheel cable slightly (do not change wheel cylinder adjusting cover setting).

½-Ton (1947-50), ¾ & 1-Ton Fwd. Control (1947-52) Pedal Type. Adjusted in same manner as other trucks (following). Also check release rod handle (under instrument panel) for ½" minimum clearance at support bracket. Adjustment provided at lower end of rod. CAUTION—This clearance necessary for correct locking action of pedal lock bar.

¾ & 1-Ton (1947-52 Exc. Fwd. Control), 1½ & 2-Ton (1947-50). After brakes are adjusted, fully release hand brake lever. Disconnect cables at cross-shaft levers on frame by removing clevis pins, pull cable out of conduit by hand until a positive stop is felt, adjust clevis on end of cable by loosening locknut and turning clevis until clevis pin can just be inserted in lever. Tighten locknut and connect cables. Check for drag and equalization. Correct by readjusting cables.

▷*CAUTION—Do not attempt to equalize parking brakes by changing wheel cylinder brake shoe adjustment.*

Toggle Lever Adjustment—This adjustment must be made whenever new rear brake shoes installed. After adjusting service (hydraulic) brakes, remove brake drum, loosen eccentric bolt locknut (lever pivot on shoe web below right end of hydraulic cylinder), hold toggle lever against shoe, turn eccentric bolt until only slight clearance between lever and bottom of slot in hand brake extension link, tighten locknut, recheck clearance. Adjust hand brake as directed above. This toggle lever is not used on 1½ and 2 Ton Trucks.

1½ & 2-Ton (1951-53). Rear wheel brakes are "Twinplex" type (see separate data on Twinplex Brakes) and parking brake is independent type on propeller shaft at rear of transmission.

RELINING BRAKES: Manufacturer recommends installation of replacement shoes furnished with linings. Hard (semi-moulded or moulded) lining used which will have glazed appearance when burnished. See Car Model page for specifications for each model. Wheel cylinder piston clamp should be installed on piston when shoes removed.

Brake Shoe Removal: With wheels and drums removed (see Brake Drum Notes below), remove shoe return spring & hold-down springs. On rear brakes remove toggle lever eccentric bolt and nut from rear brake shoe. Remove articulating link friction spring pin lock, pin and spring. Take out pin lock and pin on each shoe and remove articulating link.

NOTE—In assembling toggle lever on new shoes, see that high side of eccentric bolt is toward shoe in minimum adjustment position (high side indicated by flat ground in bolt head). Toggle lever adjusted as directed above under Hand Brake.

▷Brake Drum Removal Note—Remove drums for access to brake shoes as follows:

Passenger Cars—Rear brake drums are held on axle shaft flange by wheel mounting nuts and two screws (Zipon nuts beginning 1940). To remove drums, remove wheel and then take out screws or remove the zipon nuts on two of the wheel studs. When installing drums, see that extra hole in drum and gaskets is lined up with notch in axle shaft flange to provide oil drainage hole (or tongue on web section of drum extending into drain hole in axle shaft flange on 1942 and later models).

½, ¾, 1 Ton Truck Models—Rear brake drums are held on rear axle hub flange by two slotted screws and can be removed by taking out these screws without disturbing hub or wheel bearing adjustment.

1½ & 2 Ton Truck Models. Wheels, brake drums, and wheel hubs must be removed for access to brake shoes. This will make it necessary to adjust wheel bearings when wheels re-installed (see car model page for wheel bearing instructions).

NOTE—Brake shoes on these truck models have individual anchors.

Brake Shoe Installation: When installing shoes, see that they contact all pads on anchor plate (3 pads for each shoe) by checking clearance at each pad with .002" feeler gauge. If shoes do not touch all pads, bend anchor plate.

SERVICING: Brake Linkage (Pass. Cars). Brake cables are interchangeable (left and right).

1½ & 2 Ton Truck—Rear brake cables on these models are not interchangeable (left and right) and may be identified by string tracer woven under cable wire shield of left hand cable. *See 1½ & 2 Ton Brake Cable Change data above.*

Master Cylinder:—Piston clearance in cylinder must be .001-.005". When reassembled clearance between lip on primary piston cup and center of compensating by-pass port should be .035". *See "Hydraulic Brake Servicing" for complete data.*

Wheel Cylinders:—To disassemble wheel cylinders, with brake line disconnected and return spring on shoes removed, take out two mounting screws on backing plate. Remove cylinder, lift off adjusting cover and screw assemblies, withdraw pistons, piston cups and return spring. Examine bore. Piston clearance in cylinder should be .002-.004". Line must be bled when reinstalled.

NOTE—Wheel cylinders for front and rear wheels are of different bore and must be replaced in same wheel. No part of assembly interchangeable (see Car Model page for specifications).

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting" for complete data.*

CHEVROLET-BENDIX HYDRAULIC

Chevrolet, Pass. Cars, All Models (1951-55)
Chevrolet Corvette (1953-55)
Chevrolet, ½ Ton Trucks (1951-55)
Chevrolet Trucks, All Models except 1½ & 2 Ton Rear Brakes (1953-55)

►CHANGES, CAUTIONS, CORRECTIONS

►*1955 CHEVROLET BRAKE DESIGN CHANGE (Pass. Cars & ½ Ton Trucks):* Brake anchor adjustment has been eliminated. To compensate for this adjustment, brake shoes have been made .057-.087" smaller in diameter than drum. When a bench mounted shoe grinder is used, shoes should be ground to **undersizes** indicated above. When spindle mounted type shoe grinder is used, shoes should be ground to **actual drum diameter.**

►*POWER BRAKE NOTE:* Bendix Power Unit optional on passenger cars. Hydrovac Power Unit optional on trucks. *See "Bendix Power Unit" or "Hydrovac Power Unit" under Power Brakes.*

DESCRIPTION: Duo-Servo, single anchor, hydraulic type without eccentric adjustment.

ADJUSTMENT: Adjustments are made differently for wear (Minor Adjustment) and for new lining or shoe assemblies (Major Adjustment). Major adjustment should also be made whenever a minor adjustment is not satisfactory.

Brake Pedal Adjustment (1951-54): 7/16" (Cars), 13/16" (Trucks except Fwd. Control), 1" (Fwd. Control) between top of pedal arm and toe pan with brakes released and master cylinder pushrod against its stop. Adjust as follows:

Pass. Cars–Loosen check nut on eccentric pedal bolt, turn bolt, tighten check nut to 20-25 ft. lbs.

►*CAUTION:* If correct 7/16" clearance cannot be secured by turning eccentric bolt, adjust by installing shims under front or rear master cylinder bolts.

Trucks (Exc. Fwd. Control)–Loosen locknut at pushrod clevis, turn pushrod, tighten locknut against clevis. *NOTE*–Hold pushrod while tightening locknut.

Trucks (Fwd. Control)–Remove floor pan and cotter and clevis pins from upper end of brake pedal lever rod. Adjust for proper clearance, install upper end to brake pedal, inserting clevis and cotter pins, replace pan.

Brake Pedal Adjustment (1955): Before adjustments made, make sure pedal returns to fully released position freely, with no binding, and that pedal retracting spring has not lost its tension.

Passenger Cars–1/16" pedal movement before contact of pushrod and main cylinder piston. To adjust, loosen check nut on clevis. Turn pushrod in proper direction to secure adjustment. Tighten check nut on clevis.

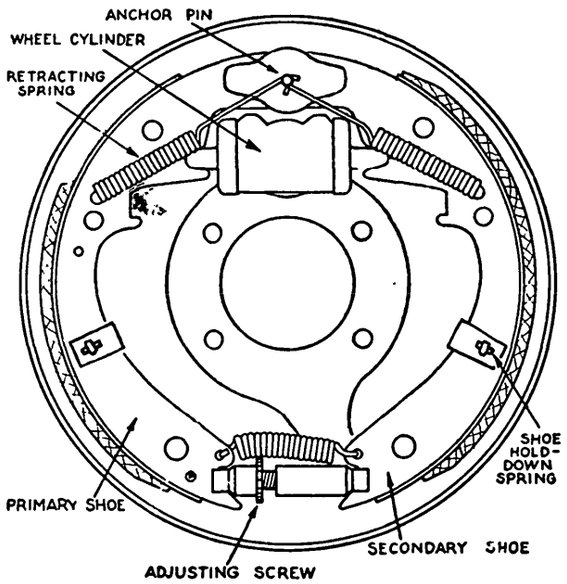
Trucks (Forward Control)–¾" clearance between top of pedal arm and toe board. To adjust, loosen check nut at rear of clevis on main cylinder pushrod. Turn main cylinder pushrod by knurled portion ahead of boot, in proper direction to secure desired clearance. Tighten check nut.

Trucks (Others)– 1¾" (Low Cab Forward), 11/16" (Others except Fwd. Control), clearance between upper corner of lower pedal arm and seal around upper pedal arm in toe board. To adjust, remove cotter pin and loosen castle nut on adjusting bolt, then rotate adjusting bolt in required direction to obtain desired clearance, tighten adjusting bolt nut, recheck clearance, reinstall cotter pin in adjusting bolt nut.

Minor Adjustment (For Wear): Jack all wheels clear of floor. On passenger cars, loosen check nut at brake cable equalizer to remove tension from brake cable. On trucks, disassemble clevis of parking brake pull rod. On all cars and trucks, remove adjusting hole covers from flange plates. Expand brake shoes by turning adjusting screw with Tool J-4707 until a light uniform drag is felt on brake drum (move outer end of tool toward center of wheel to expand shoes). On passenger cars and ½ Ton truck, turn adjusting screw in opposite direction 7 notches to relieve brake drag. On all other truck models, back off adjusting screw just enough to eliminate drum drag (not to exceed 7 notches). *(NOTE*–If more than 7 notches required to eliminate drag, a Major Adjustment is required). Replace adjusting hole covers. Reconnect and adjust parking brake (see Hand (Parking) Brake below). Check brake pedal clearance (see above).

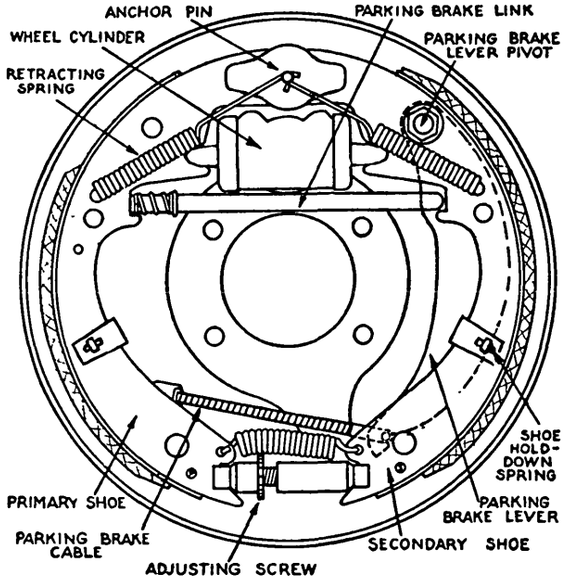
Major Adjustment (New or Relined Shoes): 1955 Pass. Cars & ½ Ton Trucks and Trucks (other than ½ Ton) adjusted differently. *See 1955 Brake Design Change above.*

1955 Pass. Cars & ½ Ton Trucks–Same as Minor Adjustment above. *See 1955 Brake Design Change above.*



1951-54 Pass. & ½ Ton, All ¼ & 1 Ton, 1½ & 2 Ton (Front Brakes): Loosen anchor pin nut just enough so that pin can be rotated (*CAUTION*–if nut loosened too much, brake springs will tilt anchor pin). With tool J-4707, turn brake adjusting screw to expand brake shoes until a heavy drag is felt on the drum. Tap brake flange plate and turn eccentric pin in direction tending to reduce drag by allowing shoes to center in drum. If drag on drum is reduced, expand shoes by tightening adjusting screw several more notches and again turn eccentric anchor pin while tapping brake flange plate. Repeat this operation until drag remains constant. Then tighten anchor pin nut to 60-85 ft. lbs. (Pass., ½ & ¾ Ton Front & Rear Brakes, 1 Ton Front Brakes), 125-150 ft. lbs. (1 Ton Rear Brakes, 1½ & 2 Ton Front Brakes). Back off adjusting screw just enough to eliminate drag but **not more than 7 notches.** If more than 7 notches required to eliminate drag, repeat adjustment procedure. Adjust parking brake (below). *NOTE*–If heavy intermittent drag noted, brake drums should be rebored and new linings installed.

HAND (PARKING) BRAKE ADJUSTMENT: Passenger Cars and Trucks adjusted differently. 1½, 2 and some ¾ & 1 Ton Trucks (1955) have propeller shaft mounted parking brakes. *CAUTION*–Service brakes must be properly adjusted before making parking brake adjustment.



1951-54 MODELS

Adjustment (Pass. Cars): Pull hand brake handle "on" 7 clicks of the pawls *(CAUTION*–this is not 7 notches). Loosen both check nuts at forward end of each wheel cable, tighten front nuts against clevis plates to tighten each cable until moderate drag secured at each rear wheel, tighten rear nuts securely to lock adjustment. Set hand brake handle 2 clicks from fully released position. No brake drag should be noticed.

CONTINUED ON NEXT PAGE

FR NT BRAKE ASSY.

REAR BRAKE ASSY.

CHEVROLET-BENDIX HYDRAULIC (Continued)

Adjustment (½ Ton Truck): Set parking brake foot pedal in fully released position. Adjust pedal pull rod clevis so that clearance between brake cross-shaft and frame crossmember at center is 1/8". Depress foot pedal 1½". Pull each wheel cable forward out of the conduit as far as possible, loosen locknut and adjust clevis on forward end of cable until hole in clevis lines up with hole in cross-shaft outer lever, connect cables. Depress foot pedal until heavy drag noted, check both wheels for equal drag. readjust wheel cable clevis as necessary. Release foot pedal, check clearance between release rod handle and rod support bracket. This clearance should be ½", correct by adjusting handle.

Adjustment (¾ & 1 Ton Truck): With parking brake pedal pedal in fully released position, adjust brake pedal pull rod clevis for correct position of cross-shaft outer levers. Center of hole in end of lever should be to rear of center-line of cross-shaft the following distance on each model: 29/32" (¾ Ton exc. Fwd. Control), ¾" (¾ Ton Fwd. Control), 11/32" (1 Ton exc. Fwd. Control), 19/32" (1 Ton Fwd. Control). Then adjust wheel cables in same manner as on Half-Ton (above).

Adjustment (1½ & 2 Ton Truck): Parking brake is independent type on propeller shaft at rear of transmission. See *"Chevrolet Twinplex" Brakes.*

1955 MODELS

Adjustment (Pass. Cars): Jack up both rear wheels. Check clearance between idler lever and mounting bracket at equalizer (approximately ¼"). To correct, disconnect equalizer, tighten check nuts on forward cable. Pull hand brake out 7 "clicks" (not same as notches). Loosen forward check nuts on equalizer and tighten rear one until there is a slight drag on both rear wheels when rotating drums. Tighten check nuts securely. Set parking lever back to 2 clicks from full release position, at which point no brake shoe drag should be felt.

Adjustment (½ & ¾ Ton Trucks using cable connected to rear wheel service brakes): Jack up both rear wheels. If clevis of parking brake disassembled, place parking brake lever in fully released position, then install clevis to brake pull rod to obtain a dimension of 1 7/16" from end of pull rod to centerline of clevis. With parking brake lever in fully released position and pull back spring in place, adjust parking brake cable at idler lever to obtain a clearance of ¼" between idler lever and rear end of slot in guide. Pull hand brake lever back four notches from fully released position. Pull cables out of conduits by hand as far as possible and assemble cables into idler lever links. Tighten nuts and locknuts. Pull back hand lever until heavy drag is felt at one wheel. Check other wheel for drag, and if any difference is noted, loosen tight wheel until equal drag is obtained. With hand lever pulled out nine notches both rear wheels should be locked so that they cannot be turned by hand. *NOTE*–If more than nine notches are required to lock brakes, check service brake adjustment.

Adjustment (¾ & 1 Ton Trucks using propeller shaft mounted parking brakes): Place the hand brake lever in fully released noteh of ratchet sector. Loosen locknut on brake pull rod. Remove cotter pin from clevis pin holding brake rod to brake cam (leave loose). Set brake cam rest flat on upper brake band bracket. Back off adjusting nuts (at lower end of spring) and adjusting nut at top of adjusting bolt (bolt joins lower part of band to bracket). *(CAUTION*–Do not remove nuts, loosen only). Remove lock wire from anchor screw. Adjust anchor screw until there is .010-.015" clearance between lining and drum at anchor screw. Tighten adjusting bolt (bolt without spring) until there is .020" clearance between drum and lower end of brake band. Tighten locknut. Tighten adjusting nut at lower end of spring until there is .020" clearance between drum and upper end of brake band. Tighten locknut. Adjust brake pull rod so clevis pin can be installed while brake cam rests flat on upper brake band bracket. Install cotter pin in clevis pin of brake pull rod and tighten locknut on brake pull rod. Install lock wire on anchor screw. Recheck all points of facing for correct clearances.

Adjustment (1½ & 2 Ton Trucks): Use independent type. *See "Chevrolet Twinplex" for data.*

BLEEDING BRAKE SYSTEM: *See "Hydraulic Brake Servicing" for complete data.*

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting" for complete data.*

BRAKE SHOE REPLACEMENT: Bonded linings used. Factory bonded shoes are recommended.

Removal: Loosen or disconnect parking brake cables. Remove brake drums. Unhook brake shoe retracting springs from anchor pin (KM0526 tool), remove brake shoe hold-down pins and springs (J-4712 tool). Spread shoes to free them from wheel cylinder connecting links, lift shoe assembly off *(CAUTION*–stops on backing plate will prevent wheel cylinder pistons coming out but brake pedal must not be depressed with brake drum off). Remove adjusting screw and spring to separate shoes. Remove parking brake strut, remove parking brake lever from secondary (rear) shoe of rear wheel brakes.

Installation: On rear wheels only, lubricate parking brake cables, lubricate fulcrum end of parking brake lever and bolt with Lubriplate or brake lube, mount lever on secondary (rear) shoe and make certain that lever moves freely. Lubricate adjusting screw threads and socket end, assemble adjusting screw and spring on shoes *(CAUTION*–adjusting screw and socket must be adjacent to primary or front shoe on **left side**, adjacent to secondary or rear shoe on **right side** for correct alignment with adjusting hole in backing plate). Install shoe assembly on backing plate, engage shoes with wheel cylinder connecting links, and connect hold-down pins and springs *(CAUTION*–Primary shoe which has shorter lining must be toward front of car. On rear brakes, connect cable to parking brake lever and install strut between lever and primary shoe as shoes are installed. Install brake shoe retracting springs *(CAUTION*–use new springs if old springs nicked, distorted, or weak). Pull shoes away from backing plate and lubricate contact surfaces with thin coat of Lubriplate or brake lube. After drums installed, make Major Adjustment (see above).

OVERHAUL: Brake Drums–Rebore brake drums if more than .010" out-of-round. Manufacturer recommends reboring to .060" oversize and use of .030" oversize lining (max. available oversize). Drum runout must not exceed .005".

Cable Lubrication–Lubricate cables when making major adjustment or if cables sticky. Use hand gun only and remove rear brake drums to make sure lubricant not being forced into brake assembly.

Master Cylinder & Wheel Cylinder–*See "Hydraulic Brake Servicing" for complete data.*

CHEVROLET TRUCK TWINPLEX

Chevrolet Trucks, 1½ & 2 Ton Rear Brakes (1951-55)

►*FRONT WHEEL BRAKE NOTE:* Front wheel brakes are Chevrolet Hydraulic (1951-52), Chevrolet Bendix (1953-55).

►*BRAKE BOOSTER NOTE:* Hydrovac Power Unit is Standard or Optional on all models.

DESCRIPTION: Two cylinder, four anchor type (each shoe anchored at each end and linked to wheel cylinder at each end). Brakes are radially self-centering.

ADJUSTMENT: Each shoe has one adjustment (adjusting screw at adjustable anchor end). Adjustment is same for both wear and for new or relined shoe clearance.

Brake Pedal Adjustment: *See "Chevrolet-Bendix Hydraulic" for data.*

Brake Shoe Adjustment: Jack up both rear wheels, remove adjusting hole covers from backing plates (two holes at each wheel–one for each shoe). Use tool J-4707 or screwdriver inserted through rear (lower shoe) adjusting hole and turn adjusting screw up (move outer end of tool toward center of wheel) until light brake drag is felt on wheel, then back off adjusting screw 3 notches for correct running clearance. Adjust upper shoe similarly by inserting tool through front adjusting hole.

Parking (Hand Brake) Adjustment: Parking brake is independent type mounted on propeller shaft at rear of transmission.

1½ & 2 Ton–Fully release brake lever. Loosen locknut on outer shoe adjusting screw then tighten to secure a clearance of .010" to .015" measured at point directly above screw. Tighten locknut. Loosen locknut on link between hand brake lever and shoe actuating lever. Tighten adjusting nut on link to secure a clearance of .010" to .015" between inner shoe and drum. Tighten locknut.

BLEEDING BRAKE SYSTEM: Pressure or manual methods can be used.

Pressure Bleeding: 1) Back off adjusting screw all the way on upper shoes of both rear wheels. Fill master cylinder reservoir to top of filler plug opening. Connect pressure bleeder to master cylinder and open valve in bleeder tank line. *(NOTE*–Bleeder tank should be charged with 25-35 lbs. air pressure and kept at approx-

CONTINUED ON NEXT PAGE

CHEVROLET TWINPLEX (C nt.)

imately this pressure during bleeding operation. End of bleeder tube must be in a bleeder jar or bottle and covered with fluid while performing all bleeding operations).

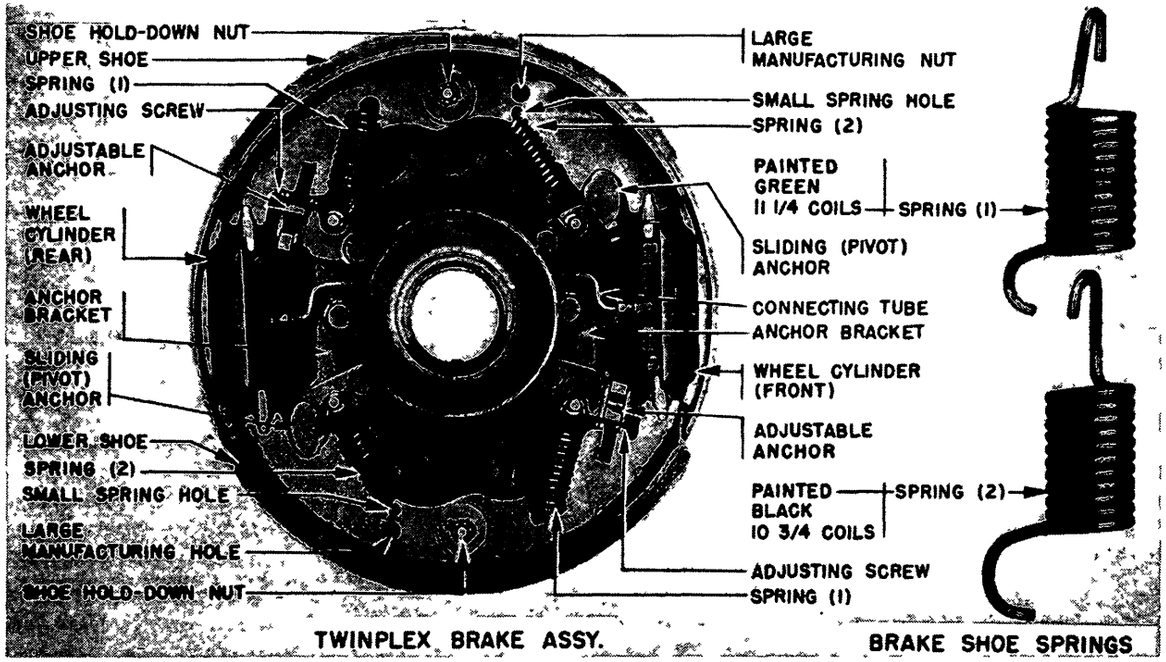
2) Connect bleeder tube to bleeder valves in following sequence, open bleeder valve and bleed until all air bubbles disappear, then close bleeder valve. Sequence as follows:

a) Hydrovac slave cylinder (No. 2 bleeder valve on end cap). *NOTE*—Will take approximately ½ pt. of fluid.
b) Hydrovac valve (No. 1 bleeder valve on top of control valve).
c) Front, rear wheel cylinder on left side.
d) Front, rear wheel cylinder on right side.
) Left front wheel cylinder (one only).
f) Right front wheel cylinder (one only).

3) Adjust upper shoe on each rear wheel with pressure tank still connected. Push down hard on brake pedal several times to centralize shoes. Disconnect pressure tank and readjust all brake shoes..

4) Apply approximately 75 lbs. pressure on brake pedal and check pedal clearance from toe board to forward edge of pedal pad. Clearance should be a minimum of 5" with floor mat removed. If reserve less than 5", rebleed Hydrovac and rear brakes in sequence outlined above.

Manual Bleeding: 1) Install adapter and automatic filler J-713. Connect bleeder tube to Hydrovac bleeder valve No. 2 (on end cap). Place end of tube in container having sufficient fluid to cover end of tube.



2) Open bleeder valve approximately ¾ of a turn, depress brake pedal a full stroke and allow it to return slowly, making sure end of tube is under surface of liquid in container. Continue operating pedal, refilling jar at master cylinder when necessary, until liquid emerging from bleeder tube is air bubble free. Close bleeder valve. Proceed to bleed system as outlined in steps **2) b)** through **f), 3) and 4)** under "Pressure Bleeding" above, using automatic filler in place of pressure tank.

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting" for complete data.*

BRAKE SHOE REPLACEMENT: Brake linings are riveted type and can be installed in the field after shoes have been removed.

R moval: Support rear end of truck on stands, remove rear wheels, back off adjusting screw for each shoe (two per wheel), remove brake drums by taking out 3 retaining screws on face of drum. Disconnect and remove all shoe pull back springs, remove hold-down nut on washer on web of each shoe. Disengage shoes from cylinder links, lift shoes out.

►*CAUTION: Stops on backing plat will prev nt wheel cylind r pistons from coming out but brak p dal must n t b d pr ssed when drums ar ff.*

CHEVROLET TWINPLEX BRAKE ASSY.

Installation: Lubricate shoe primary (sliding pivot) anchors and all shoe bearing surfaces on brake flange plate with light film of Lubriplate or Brake Lube. Install shoes, engaging ends of shoes with anchors and slotted ends of wheel cylinder links, and making certain that hold-down bolt enters hole in shoe web. Lubricate hold-down bolts and washers lightly with Lubriplate or Brake Lube, install washer and nut on each hold-down bolt and tighten nuts loosely. Install shoe pull back springs (*CAUTION*—see illustration and Note below for correct spring installation). Tighten each hold-down bolt nut until clearance between edge of shoe and contact face on flange plate is .010" (measure with feeler gauge). Install drums and adjust brakes.

►*BRAKE SHOE PULL BACK SPRING NOTE:* Different spring used at each end of shoes. Install springs thus: **Spring at Primary (Sliding Pivot) Anchor End of Shoe**— 10¾ coil, 90 lb. type, painted BLACK for identification, with LARGE hook at shoe end of spring. Install spring with this large hook engaging small hole in shoe web.

►*CAUTION: This spring must not be engaged in larger manufacturing hole in web adjacent to spring hole.*

Spring at Secondary (Adjustable) Anchor End of Shoe— 11¼ coil, 70 lb. type, painted GREEN for identification, with SMALL hook at shoe end of spring. Install this spring with this smaller hook engaging the large hole in the shoe web adjacent to the shoe adjusting wheel.

►*CAUTION: Interchanging springs or incorrect installation will result in unev n brak shoe w ar and unsatisfactory brake operation.*

OVERHAUL: Brake Drums—Rebore brake drums if more than .010" out-of-round. Manufacturer recommends reboring to .060" oversize and use of .030" oversize lining (max. available oversize). Drum runout must not exceed .005".

Master Cylinder: *See "Hydraulic Brake Servicing".*

Wheel Cylinders: To remove wheel cylinders, first remove brake shoes, then take out capscrews holding wheel cylinder on backing plate and remove **both cylinders and connecting lin as a unit.**

Disassembly—Disconnect line linking the two cylinders, remove rubber boots and shoe connecting links, withdraw pistons and rubber cups and springs from cylinder. *CAUTION—Do not r mov rubber cups (piston rings) from grooves in pistons unl ss th s cups being replaced.*

Inspection & Repair—Inspect cylinders for scores, scratches, and corrosion. Light scratches or lightly corroded areas may be cleaned up with crocus cloth, replace cylinder if these cannot be polished out. (*CAUTION*—Honing cylinders not recommended). Replace piston cups and cylinder boots if swollen or damaged. Piston clearance in cylinder .002-.004".

Reassembly—Dip all parts in brake fluid. Install piston and cup assemblies with cupped side toward spring or inward. (*CAUTION*—use care not to damage edges of cups). If new cups being installed, use tool J-4705 and install cups with open end toward flat end of piston.

FORD-LOCKHEED HYDRAULIC
FORD & MERCURY

Ford 6 & V8 Pass. Car Models (1946-48)
Ford Comm'l & Truck, All Models (1939-48)
Ford F-2 ¾ Ton Truck (1948-51)—See Note
Ford F-3 ¾ Ton Spec. Trk. (1948-51)—See Note
Ford F-3 Parcel Del. (1949-51)—See Note
Ford F-3 Truck Parcel Del. (1948-Early 1951 All Whls., Late 1951-52 Front Whls. Only)
Ford F-4, 5, 6 Trucks (1948-52)
Ford F, C-700; F, C-750 Trucks 1953-55 Front Wheels)
Mercury, All Models (1946-48)

►*1955 MASTER CYLINDER PUSHROD INSTALLATION CAUTION:* Master cylinder pushrod and clevis pin are installed in lower hole in brake pedal on all models

►**BRAKE TYPE NOTE: Ford & Mercury 1946 & Later Passenger Cars.** The brakes on these models are "self-centering" type and do not have adjustable anchor pins.

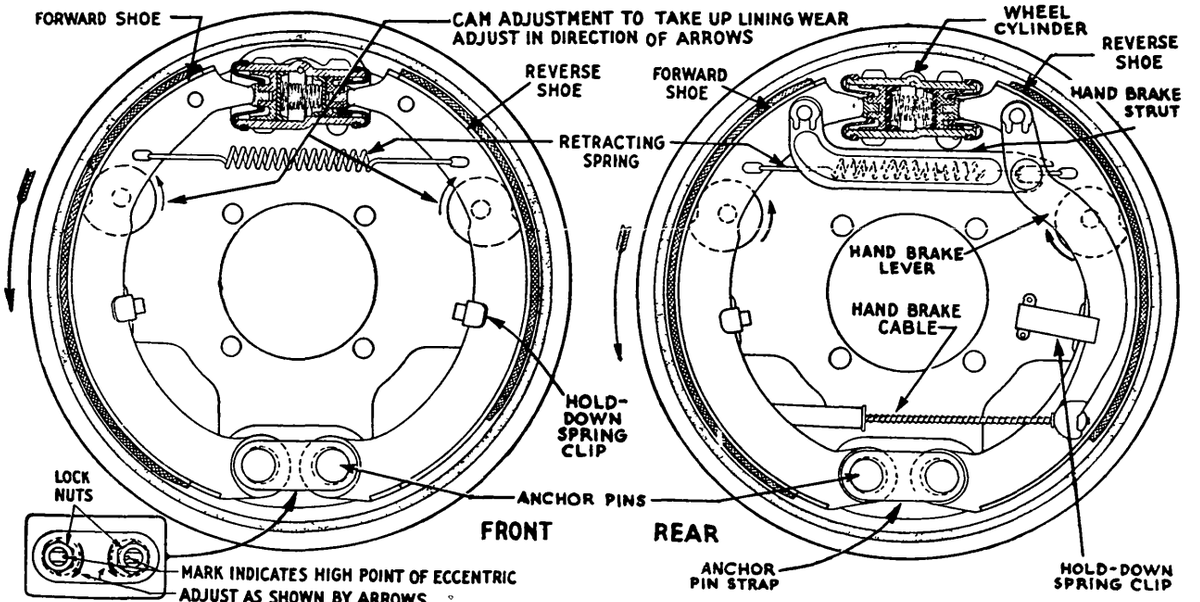
Series F-2 (Front & Rear), F-3 (Front)—Lockheed "self-centering" hydraulic type without anchor pin adjustment (eccentric adjustment only).

Series F-3 Parcel Delivery (Front & Rear)—Brakes are double-anchor hydraulic type with eccentric and anchor pin adjustments. Late 1951 model has Ford-Bendix hydraulic brakes on rear wheels only.

Series F-3 (Rear only), F-5 & F-6 (Front & Rear): Lockheed double-anchor hydraulic type with eccentric and anchor pin adjustments.

DESCRIPTION & OPERATION: Lockheed two shoe, double anchor type. **Two shoes per wheel, each mounted on individual eccentric anchor pin at lower or 'heel' end and bearing directly against opposed pistons of stationary wheel cylinder at upper or 'toe' end.**

Anchor Pins (All Ford & Mercury Self-centering type Brakes). On these models, anchor pins are fixed on backing plate and have special elongated washers which engage elongated holes in brake shoe web. With this mounting, shoes tend to "center" themselves in drum when brakes are applied.



Wheel Cylinders:—Rigid type mounted on backing plate with opposed pistons which bear directly against toes of brake shoes. Pistons are sealed by rubber cups held against piston heads by central spring and dirt is excluded from cylinder by rubber boot fitting over end of cylinder and brake shoe.

Master Cylinder:—Compensating type with integral supply tank. Similar in design to type used on other Lockheed Hydraulic Brake applications.

Parking Brake: On Pass. Cars, ½ and the 1949-50 & early 1951 ¾ Trucks (exc. Par. Del.) hand lever applies rear service brakes through cables. On other truck models, hand lever applies independent brake mounted on propeller shaft at rear of transmission.

BLEEDING BRAKE SYSTEM: *See "Midland Hy-Power" Power Brakes for procedure with Power Brakes and "Hydraulic Brake Servicing" for brakes without booster.*

Brake Pedal Adjustment:—Brake pedal must have ¼-½" free movement (measured at pedal pad). This movement is the movement of the pedal before the push rod touches master cylinder piston. To adjust, loosen locknut on brake pedal-to-master cylinder rod, rotate push rod until pedal free play is within limits. Tighten locknut.

FORD-LOCKHEED BRAKE ASSY.

►*CAUTION—Do not make cables too tight or the rear brake shoes will be pulled off their anchors.*

►*ADJUSTMENT CAUTION:* **First jack up all four wheels, remove one front wheel and inspect lining (to determine if new linings required), re-install wheel. Check front wheel bearing adjustment, spring shackles, shock absorber links, and radius rod mountings, tighten steering connections. Place hand lever in released position. Adjust each wheel as follows:**

Minor Adjustment (For Wear):—Install wrench on eccentric adjusting cam on backing plate with wrench handle upward, turn cam by moving wrench handle out toward wheel rim until shoe is tight in drum, then turn cam back until wheel just turns freely without drag (do not turn cam back more than enough to free wheel, desired setting is with least possible amount of clearance). After adjusting forward shoe, repeat adjustment on rear shoe, then adjust all other wheels in same manner. Check pedal reserve, if reserve less than half total travel, repeat adjustment (if pedal is 'spongy', bleed lines).

►*CAUTION—Clearance between shoes and drum should be least amount possible without drag (no specific clearance specified).*

Major Adjustment (For relined brakes, etc.):—NOTE *This adjustment not required on 1946-48 Pass. Cars and Light Trucks with "self-centering" type brakes.*

Before installing brake drums, loosen eccentric anchor pin locknuts and turn each anchor pin so that marks on flatted ends of pins are together (marks indicate 'high' side of eccentric and in this minimum position will allow drums to be installed over new linings), turn eccentric adjusting cam for each shoe to minimum position. With drums installed, turn eccentric anchor pin toward adjacent anchor pin (wrench handle upward) until brake shoe is tight against drum, then back anchor pin off slightly until wheel turns freely without any drag. Hold anchor pin from turning and tighten locknut securely. Then adjust eccentric adjusting cam (see Minor Adjustment above) for correct toe clearance of the brake shoe. Adjust both shoes in each wheel in this manner, then adjust hand brake.

	Heel	Toe
Brake Shoe Clearance	.007"	.010"

Parking Brake Adjustment Caution: Different types of linkages used. Adjust each model as follows:

Passenger Cars—Place hand brake control lever in fully released position. Depress the brake pedal until rear brake shoes applied firmly against drums, leave pedal in this position while adjustment being made. Pull forward on cables to remove all slack, adjust clevis on end of hand brake cable so that, with foot brake applied as above, end of hand lever has ½" travel before slack in cables is taken up. Release foot brake pedal. With hand lever in released position, check that rear wheels are free of any brake drag.

F-1 ½ Ton, F-2, 3 ¾ Ton (1948-Early 1950)—After adjusting service brakes, place hand lever in fully released position. Apply enough pressure to depress brake pedal until rear brake shoes are applied firmly. Adjust each wheel cable at equalizer lever on frame cross-member by taking out clevis pin, loosening locknut, and turning clevis on cable end fitting until all slack is removed from cables and mounting bolt is centered in slot in equalizer plate. Adjust hand lever cable by taking out clevis pin, loosening locknut, and turning clevis on cable end fitting until hand lever has approximately ½" movement (with brake shoes applied as above). Release pedal, make certain rear wheels free of drag.

CONTINUED ON NEXT PAGE

FORD-LOCKHEED HYDRAULIC (C nt.)

F-2, 3 ¾ Ton (Late 1951), F-3 Parcel Del. (1949-51), F-4 1 Ton, F-5 1½ Ton & F-6 2 Ton (1948-52)—Hand brake is independent contracting band type operating on drum on propeller shaft at rear of transmission *See 1½ & 2 Ton adjustment instructions following:*

1½ & 2 Ton Truck Models (1948-52)—Release hand brake lever. See that flat of cam rests on brake band ear (if not, remove clevis pin from rod above cam and adjust clevis as necessary so that flat of cam rests on ear of band, install clevis pin. Remove lockwire and turn anchor screw (on bracket on left side) in until clearance between lining and drum is .010" at this point, replace lockwire. Loosen locknut and turn bracket adjusting screw nut (on right side, adjusting screw head on bracket is slotted) until clearance between lining on lower half of band and drum is .010", tighten locknut. Then tighten nut on lower end of band adjusting rod (below ear on lower end of band) until clearance between lining on upper half of band and drum is likewise .010". Recheck rod linking cam and brake lever. Make certain that adjusting nuts are secured with lockwire.

OVERHAUL: *NOTE.* Factory recommends installation **of factory reconditioned brake shoes (with new lining installed) whenever lining worn so that replacement required. Before removing brake shoes, install clamp on wheel cylinders (to retain wheel cylinder pistons) and be careful not to depress brake pedal with shoes off. This will eliminate necessity of bleeding lines when shoes installed.**

Brake Shoe Removal: Remove each type as follows

Self-centering Type Shoes—Remove brake shoe return spring, take out anchor pin cotter pins, remove anchor pin plate Remove brake shoes, anchor pin washers, and anchor pin bushings On rear brakes, unhook parking brake cable, remove parking brake link and lever.

Adjustable Anchor Type Shoes—Remove brake shoe return spring, remove nuts and lockwashers on anchor pins. Remove anchor pins and anchor pin plate. Remove brake shoes and anchor pin bushings On rear brakes, disconnect parking brake cable and remove parking brake link and lever.

Relining Brake Shoes: Lining should be replaced when worn to point where rivet head less than 1/32" below surface of lining. Inspect shoes for distortion or looseness between rim and web. Clean shoe rim and remove all burrs or high spots before installing new lining After riveting, new lining must be snug against shoe with not more than .005" separation midway between rivets.

►*BRAKE LINING NOTE*—Lining furnished in brake lining kits is ground in production and does not require grinding after installation.

Brake Shoe Installation:—Assemble retracting spring to shoes (and hand brake lever and link parts for rear wheels). Turn eccentric adjusting cams to minimum position. Hold shoes so that anchor pin ends overlap and upper ends spread sufficiently to enter wheel cylinder pistons, engage shoes in piston slots, spread lower ends of shoes until they are engaged under flat lip of hold-down springs. Install anchor pins making certain that eccentric is in place in hole in brake shoe and that anchor pin engages eccentric. Turn anchor pins so that notch in flatted end of each pin is lined up with notch in opposite pin, install anchor pin locknuts, connect hand brake cable to lever. Adjust shoes as directed in Major Adjustment above.

Master Cylinder & Wheel Cylinder Disassembly and Overhaul:—All service operations same as on other Lockheed brake installations. *See "Hydraulic Brake Servicing" for complete data.*

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting" for complete data.*

FORD TRUCK BENDIX UNI-SERVO

Ford Trucks—F-2 & F-3 exc. Parcel Del. (1951-52). Front Wheels Only.

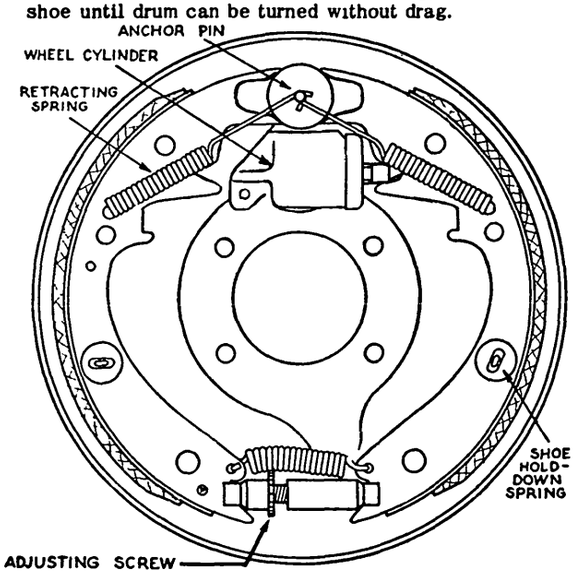
Ford Trucks—F-250; F, P-350, F, C, P-500, F, C-600 (1953). Front Wheels Only.

Ford Trucks—F-250, F, P-350; B, C, F, P-500, B, C, F-600 (1954-55). Front Wheels Only.

►*REAR BRAKE CAUTION· Different type brakes used on rear wheels as follows·*

F-2, 3, F-250, F, P-350—Ford-Bendix Hydraulic, Duo-Servo type *See "Ford, Lincoln, Mercury Bendix".*

B, C, F, P-500; B, C, F-600—Ford "Self-Centering" type. *See "Ford Truck Self-Centering".*



►*POWER BRAKE NOTE "Hydrovac" or "Midland Hi-Power" Standard or Optional on these trucks. See "Hydrovac" or "Midland Hi-Power" under Power Brakes.*

►*1955 MASTER CYLINDER PUSHROD INSTALLATION CAUTION:* On F-100 Trucks master cylinder pushrod and clevis pin are installed in upper hole in brake pedal, on F-250, F-350 and F, B-500 pushrod and clevis pin are installed in upper hole with conventional brakes, and in lower hole with booster brakes, on B, C, F-600 pin and pushrod are installed in lower hole of brake pedal for both conventional and booster brakes.

DESCRIPTION: Bendix "Uni-Servo" single anchor, hydraulic type with single-acting wheel cylinder mounted on the backing plate and actuating the primary shoe through a strut (no direct connection to secondary shoe). Brake shoes are conventional Bendix type (joined by adjusting screw at lower end, single anchor between shoes at upper end with retracting springs hooked to each shoe and anchor pin). Wheel cylinder has single piston and cup with a return spring seated in the end of the cylinder.

ADJUSTMENTS: Make adjustments with brake drums at normal temperature and with wheels either jacked up or contacting road (if wheels on road so they cannot be checked for drag, make this check by striking drum with a hammer—sound will be deadened if shoes contacting drum).

Minor Adjustment: Remove adjustment hole cover from brake carrier plate. Rotate adjusting screw, with a suitable tool, until shoe begins to drag, then back off shoe until drum can be turned without drag.

UNI-SERVO BRAKE ASSY.

Major Adjustment: Wedge primary shoe against the drum by inserting a .010" feeler gauge through slot in drum at center of secondary shoe and expand shoes by turning adjusting screw. Then adjust adjusting screw and anchor pin (slotted type) for .010' clearance at each end of secondary shoe (measure 1½" from each end of shoe).

Brake Pedal Adjustment: Brake pedal free travel should not be less than 3/16" nor more than 3/8" before push-rod touches master cylinder piston. Adjustable at master cylinder pushrod.

Parking Brake Adjustment: Set lever to first notch. Observe position of cam to make sure flat portion is resting on brake band bracket. If cam not flat with bracket, remove clevis pin from upper part of cam, then adjust clevis rod to allow flat portion of cam to rest on brake band bracket. Install clevis pin and cotter pin. Remove lock wire from anchor adjusting screw, turn adjusting screw clockwise until clearance of .010" is established between brake lining and brake drum at anchor bracket. Loosen locknut on adjusting screw for lower half of brake band, adjust screw to establish .010" between brake lining and drum at lower half of brake band. Tighten locknut. Turn upper band adjusting nut until .010" clearance established between upper half of band and drum. Be sure to install lock wire in anchor adjusting screw.

BLEEDING BRAKE SYSTEM: *See "Hydraulic Brake Servicing"*

BRAKE SHOE & DRUM REPLACEMENT: *See "Ford, Lincoln, Mercury Bendix"*

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting"*

OVERHAUL: Master Cylinder & Whe l Cylind rs—*See "Hydraulic Brake Servicing"*

FORD, LINCOLN, MERCURY BENDIX HYDRAULIC

Ford Pass. Cars (1949-55)
Ford F-1, 100 Truck (1948-55)
Ford F-2, 3 Truck (Late 1951-52)—Rear Wheels
Ford F-250; F, P-350 Trucks (1953-55)—Rear Wheels
Lincoln, All Models (1946-55)
Mercury, All Models (1949-55)
Thunderbird (1955)

►CHANGES, CAUTIONS, CORRECTIONS

►*POWER BRAKE NOTE: Power Brake units standard or optional as follows (See Power Brakes):*
Ford—"Hydrovac" or "Midland" Brake Power Unit.
Lincoln & Mercury—Bendix Brake Power Unit.

►*FORD TRUCK FRONT BRAKE CAUTION:* Ford-Bendix "Uni-Servo" used on front wheels of above listed trucks except F-1, 100.

►*1949-52 HAND BRAKE CABLE INTERFERENCE CORRECTION & PRODUCTION CHANGE*—If cable or conduit rubs on rear tires, correct as follows:

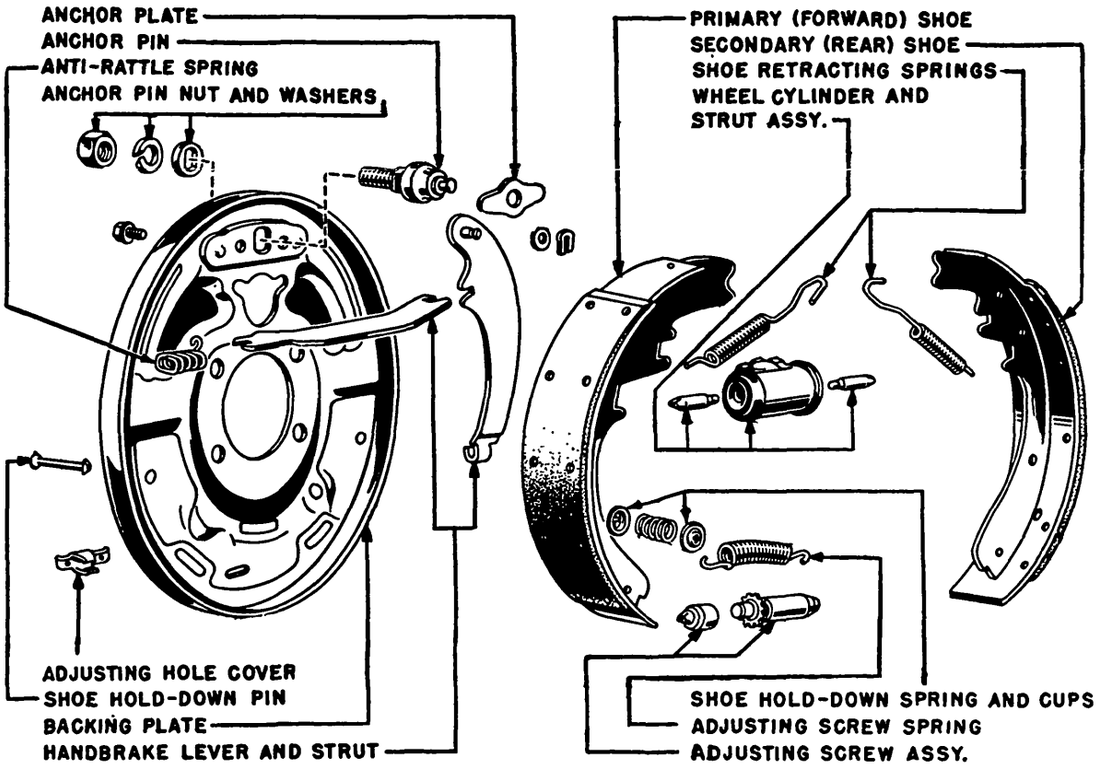
Ford Pass. Cars—Remove cable conduit clip on frame, revolve conduit toward center of car (twist conduit at carrier plate if necessary), re-install clip. A new parking brake assembly (Ford No. AB-2275-E) entered production Aug. 19, 1952. Assembly is shorter and prevents conduit rubbing on rear tires, and is interchangeable on earlier cars.

Mercury—A new hand brake cable rear bracket, Mercury Part No. MA-2530-B (Right), and MA-2531-B (Left) entered production April 7, 1952. New brackets are interchangeable with earlier type brackets.

►*FORD HAND BRAKE LINKAGE CHANGE (To lessen effort required to set hand brake on First Cars):* On creased by drilling new hole in equalizer lever and shifting wheel cable connector to this new hole.

Passenger Cars—Drill new 5/16" hole 13/32" from existing hole toward pivot end of lever.

Station Wagon & Convertible—Drill new 5/16" hole at point 9/16" from center of existing hole toward pivot end of lever (new hole center will be 1¼" from center of pivoting notch in lever).



►*NOTE—This change made in production on later cars.*

►*CAUTION*—If above procedure does not correct complaints of hand brake being hard to apply, remove hand lever assembly, check for burrs on hand brake shaft, clean up shaft with round file, apply light film of lubricant when reassembling.

►*LINCOLN & MERCURY HAND BRAKE LINKAGE CHANGE (for improved operation on First Cars):*

Re-route Brake Cable. Disconnect cable at lever, remove all clips down to spring clip at center of frame "X" member (do not disturb this clip), re-route cable and install new clips as follows: Install No. E.D. 11A-17278 clip at transmission case bottom rear shifter cover bolt, E.D. 353364-SB at brake master cylinder front bolt (route cable over top of steering column tube, install clip E.D. 353364-SA at upper rear corner of front fender apron (on Lincoln 121" WB, use clip 11A-14598 installed on fender apron 1½" to rear of wiring harness clip), route cable through hole in dash (use 91A-14602-A1 rubber grommet) attach cable and adjust hand brake.

►***CAUTION—Avoid all sharp bends and kinks when installing the brake cable. Tape brak cable and hood latch control cables together to prevent rattles.***

FORD-BENDIX REAR BRAKE ASSEMBLY
(FRONT BRAKE SAME EXCEPT HANDBRAKE PARTS NOT USED)

Re-locate Cable Connection on Hand Lever (Mercury only)—Drill new 5/16" hole in hand brake lever at point 1.38" from center of pivot hole in lever and shift cable connection to this new hole to improve leverage.

Lubricate Hand Brake Control—Lubricate following points with Lubriplate or equivalent (use sparingly): 1. Lever Pivot at ratchet bar, 2. Ratchet Bar, 3. Dash Hinge Bracket, 4. hand lever and body bracket Bolt & Contact Surface.

Align Hand Brake Control—To insure alignment, first attach hand brake lever at body bracket, second attach ratchet bar housing assembly to instrument panel with hand lever in fully released position.

►*1949-54 MERCURY BRAKE "SQUEAL" CORRECTION:* Brake Drum Silencer Spring, Part No. OM-1140 furnished for all 1949-54 Models. To install, proceed as follows:

Drums with Circumferential Grooves—Hook ends of spring together and roll onto drum, stopping next to raised rib near open end of drum.

Drums without Grooves—Hook ends of spring together and roll onto drum, stopping next to raised rib near open end of drum. Use a 5/16" round-nosed chisel and raise metal against spring in four places equally spaced around drum to retain spring in position.

►*BRAKE PEDAL BINDING CORRECTION*—Remove master cylinder pushrod-to-pedal eccentric bolt and bushings. Dip bushings in light engine oil and re-install.

►*1954 DESIGN & ADJUSTMENT CHANGE:* Front brakes of all 1954 Passenger cars have eccentric adjustment. Position of front brake assembly has been rotated to give access to anchor pin. A secondary shoe adjusting spring holds secondary shoe in released position. An eccentric, located behind secondary shoe, provides the stop. See Major & Minor Adjustments (With Eccentric) for adjustment procedures. Rear wheel brakes remain the same as previous models (without eccentric adjustment).

►*1955 FORD TRUCK MASTER CYLINDER PUSHROD INSTALLATION CAUTION:* On F-100 Trucks master cylinder pushrod and clevis pin are installed in upper hole in brake pedal for both conventional and booster type brakes; on others, master cylinder pushrod and clevis pin are installed in upper hole

CONTINUED ON NEXT PAGE

FORD, LINCOLN, MERCURY BENDIX (Cont.)

in brake pedal for trucks with conventional brakes and in lower hole for trucks with booster brakes.

►*1955 FORD PASS. CAR BRAKE LINING PRODUCTION CHANGE:* Effective approximately August 1, 1955, under-ground brake lining became effective in production. Adjustment procedures for both underground and uniform-ground linings are the same.

►*1954 FORD P-350 TRUCK HAND BRAKE CABLE INTERFERENCE CORRECTION:* To prevent interference between hand brake cable and clutch pedal, attach one clip, Part No. 91A-2279, to upper bolt in seam of left front wheel splash shield, and another clip, Part No. 352605-S8, to boss at top left rear corner of cylinder block. Cable should pass from hand brake lever to 91A-2279 clip, then up to 352605-S8 clip on engine. Be sure cable is positioned between steering column and sheet metal.

►*BRAKE SHOE RETRACTING SPRING PRODUCTION CHANGE & REPLACEMENT CAUTION (Pass. Cars):* Effective production Aug. 24, 1955 a new oil tempered brake retracting spring, Part No. B5A-2035-A, has been used to improve brake life and performance, and should be installed on units produced prior to above date. When installing spring, avoid bending end hooks or stretching beyond attaching point.

►*1955 FORD PASS. CAR PRIMARY BRAKE LINING & SHOE PRODUCTION CHANGE:* A new primary brake lining and modified brake shoe has been released for front and rear wheels. New lining is shorter in length, and is intended to reduce "pulling or diving" on brake application. **New linings may be installed on earlier type shoes**, and earlier type linings may be used on the new type shoes. In either case, two new holes must be drilled in the shoes using the holes in the lining as a template. *NOTE*—Shortened end of primary linings must be located at anchor (upper) end of shoe. When installing new linings on earlier type shoes, two holes must be drilled at anchor end. When relining brakes, make sure new type (shorter) and old type linings are not mixed.

Lining Kits

Car Model	Front Wheel Kit	Rear Wheel Kit
Car	B5A-2007-G	B5A-2007-H
Car (Hvy. Duty)	B5A-2007-L	B5A-2007-M
Sta. Wgn., Sed. Del.	B5A-2007-J	B5A-2007-K
Thunderbird	B5S-2007-B①	

①—Lining kit for both front and rear wheels.

►*1955 FORD PASSENGER CAR ADJUSTMENT CHANGE:* Eccentric is located on primary shoe. Initial adjustments made on primary instead of secondary shoe. Adjusting spring is no longer used.

►*1955 FORD PASS. CAR BRAKE LINE INTERFERENCE WITH OIL FILTER CORRECTION:* Clip, Part No. B4A-2244-A, and attaching screw, Part No. 39883-S7, now available to secure brake line to rear side of No. 2 crossmember. On vehicles not equipped with additional clip (now used in production), and on which interference is encountered, proceed with installation of additional clip as follows: Locate and mark spot on No. 2 crossmember 4½" to left, and 4 15/16" up from center of existing clip at left hand rear side of crossmember. Drill 9/32" hole at this spot. Position brake line on crossmember, and secure line with clip and screw. *NOTE*—Brake line will move far enough to permit installation without bending or crimping line.

►*1955 LINCOLN & MERCURY FRONT BRAKE PRODUCTION CHANGE:* Front brake eccentric adjuster has been eliminated on later cars and no eccentric adjustment is required. See Adjustments below.

►*1955 LINCOLN & MERCURY BRAKE ADJUSTMENT CHANGE:* Adjustment procedures are affected in that eccentric cam is now spring loaded, which eliminates need for lockout to retain it in position. See Adjustments below and also Production Change above.

DESCRIPTION

DESCRIPTION: Duo-Servo, single anchor, hydraulic type. *NOTE*—Eccentric used **on front wheels** of all 1954 models, 1955 Ford Passenger Car models, and early 1955 Lincoln and Mercury models. All 1946-53 models and late 1955 Lincoln and Mercury models do not use eccentric

ADJUSTMENTS

ADJUSTMENTS: Before making any adjustments, jack up all four wheels, check brake pedal clearance (see below), fully release hand brake lever and make certain that all wheels turn free. Then adjust as directed below.

BRAKE PEDAL ADJUSTMENT

Brake Pedal Adjustment: Pedal must have more than ¼" but less than 7/16" free travel (Ford Pass. Cars, Lincoln, Mercury), more than 3/16" but less than ⅜" free travel (Ford Trucks) before master cylinder piston begins to move.

Ford (Pass. Cars), Lincoln, Mercury—Loosen locknut on eccentric bolt attaching brake pedal to master cylinder pushrod, and turn bolt for desired free play.

Ford (Trucks)—Loosen locknut on master cylinder pushrod, remove clevis pin at brake pedal, turn pushrod in or out as necessary, tighten locknut.

MINOR ADJUSTMENT

Minor Adjustment (Except 1954-55 Ford Pass. Cars):
Ford—Turn adjusting screw for each wheel (accessible through slot in backing plate) until drum can just be turned by hand, then back off adjusting screw until shoes are just free and wheel revolves without drag.
Lincoln & Mercury—Use feeler gauge to set shoe clearance to .010". See Major adjustment for data.

Minor Adjustment (1954-55 Ford Pass. Rear Wheels): Disconnect parking brake cable at equalizer clevis pin. Turn adjusting screw (toward axle) until wheel can just be turned by hand. Back off adjusting screw 10 to 14 notches (away from axle). Wheel should rotate freely. If drag felt, Major Adjustment is required. Connect parking brake cable and adjust. Apply brakes and measure distance from pedal pad to floor board. If distance less than ½ of total travel, Major Adjustment is required. *NOTE*—If car has booster brakes, check must be made with engine running.

Minor Adjustment (Lincoln & Mercury Front Wheels): Two adjustments required as follows:
Eccentric Cam Adjustment—Raise car and remove front wheels. Insert .010" feeler gauge through drum slot and check clearance at lower end of secondary shoe. Feeler gauge should be just snug. To adjust clearance, rotate cam adjusting stud in direction of forward wheel rotation to decrease clearance. To increase clearance, rotate cam in opposite direction. Check clearance at upper end of secondary shoe (.010"). The clearance at both ends should be same within .003". Where variation is greater, make Major Adjustment.
Adjusting Screw Adjustment—Remove adjusting hole cover and insert .010" feeler between lining and drum near lower end of primary shoe. Hold primary shoe snug against feeler. To decrease secondary shoe clearance, rotate adjusting screw from top to bottom, and to increase secondary shoe clearance rotate adjusting screw from bottom to top. Then recheck clearance at both ends of primary and secondary shoes. Check that all brake drums are free of lining drag.

Minor Adjustment (1954-55 Ford Pass. Car Front Wheels): Check anchor pin with 16" wrench (if loose, Major Adjustment is necessary). Expand brake shoes by turning adjusting screw (star wheel) toward center of brake until it is just possible to rotate drum. Back off adjusting screw 10 to 14 notches. While slowly rotating drum, turn eccentric cam in direction of forward rotation until slight drag is felt, then back off eccentric cam to have a freely rotating drum. *NOTE*—Tap backing plate with hammer when backing off eccentric cam to center shoes. If drum does not rotate freely after backing off adjusting screw and carefully setting eccentric cam, a Major Adjustment is required.

MAJOR ADJUSTMENT

Major Adjustment (Except 1954-55 Ford Pass: Cars):
►*CAUTION: Recommended procedure for Ford is not the same as for Lincoln & Mercury.*
Ford—Wedge the primary shoe out against the drum by inserting a .010" feeler gauge through the slot in the drum at the center of secondary shoe and expand shoes by turning adjusting screw. Then adjust adjusting screw and anchor pin (slotted type) for .010" clearance at each end of secondary shoe (measure 1½" from each end of shoe).
Lincoln & Mercury—The shoe clearance should be .010" at all points. Check by inserting .010" feeler through slot in brake drum and measuring clearance at several points. Adjust by turning adjusting screw (accessible through slot in backing plate) and by shifting anchor pin if necessary (pin hole is slotted and will allow an up-and-down shifting of anchor pin to correctly center shoes). Torque anchor pin nuts to 80-120 ft. lbs.

Major Adjustment (1954-55 Ford Pass. Car Rear Wheels): Adjust in manner similar to front brakes, omitting eccentric cam adjustment. Connect parking brake cable and adjust.

Major Adjustment (Lincoln & Mercury Front Wheels):
NOTE: Major adjustment performed only if Minor Adjustment unsatisfactory, or that upper end of anchor has less clearance than lower end.
Anchor Pin-Eccentric Adjustment—Complete operations of rotating Cam Adjusting Stud for secondary shoe clearance as shown in Minor Adjustment. Then adjust anchor pin and eccentric to obtain .010" clearance at each end of secondary shoe. To adjust anchor pin end, loosen anchor pin nut one full turn, tap pin lightly upward, with soft hammer, to decrease clearance or downward to in-

CONTINUED ON NEXT PAGE

FORD, LINCOLN, MERCURY BENDIX (Cont.)

crease clearance. Recheck lower clearance to insure that anchor pin adjustment did not alter lower end of secondary shoe clearance. If lower secondary shoe clearance not correct insert .010" feeler between lining and drum of primary shoe at lower end of shoe and with shoe snug against feeler turn adjusting screw from top to bottom to decrease secondary shoe clearance and from bottom to top to increase clearance. Recheck all clearances and repeat anchor pin adjustment if necessary to maintain a greater clearance at anchor pin end not to exceed .003". Recheck all clearances, replace wheels and road test. Torque anchor pin nuts to 80-120 ft. lbs.

Major Adjustment (1954 Ford Pass. Car Front Wheels): Expand brake shoe by turning adjusting screw (star wheel) toward center of brake until it is just possible to rotate drum. Back off screw 10 to 14 notches. Position drum so inspection slot is within 1" of upper end of secondary rear lining. Insert a .010" feeler between lining and drum at this point. Loosen anchor pin nut one turn and tap with a soft hammer to establish a .010" clearance. Do not tighten anchor pin locknut at this time. Insert .010" feeler 1" from adjusting screw end of secondary lining. Adjust eccentric to obtain .010" clearance. Recheck clearance at anchor end of secondary lining. After clearance has equalized at .010" at both ends of lining, tighten anchor pin locknut to 65-85 ft. lbs. Recheck clearance on secondary shoe to make sure anchor pin has not moved. Check clearance at center of primary lining with .010" feeler. Turn adjusting screw (star wheel) to obtain a .010" clearance on primary lining.

Major Adjustment (1955 Ford Pass. Car Front Wheels): Turn adjusting screw toward center of brake until shoes are tight in drum. Push adjusting screw star wheel toward primary shoe lining. Position drum so inspection hole is within 1" of upper end of secondary (rear) shoe lining. Insert a .010" feeler between lining and drum at this point. Push secondary shoe against feeler by pushing on adjusting screw star wheel. Remove feeler, rotate drum until slot is 1" above lower end of secondary shoe. Do not force shoe out of position. Check clearance at this point with feeler gauge. If greater or less than .010", loosen anchor nut approximately 1 turn. Tap anchor pin in direction of greater clearance (up or down) with soft hammer. After clearance of secondary shoes have been equalized at .010" at both ends, tighten anchor pin nut to 65-85 ft. lbs. Recheck clearance on secondary shoe to be sure anchor pin did not shift. Rotate drum so slot is over any part of primary shoe lining. Insert a .010" feeler between drum and lining. With feeler in place, move drum back and forth keeping inspection slot and feeler over primary shoe lining, at same time rotating eccentric cam in same direction as forward wheel rotation, until a .010" clearance is established between closest point of lining and drum. This should provide clearance for both shoes. If any drag noted, adjusting screw may be backed off another 1 or 2 notches.

HAND BRAKE ADJUSTMENT

Hand Brake Adjustment: Ford (Pass. Cars), Lincoln, Mercury. Be sure service brakes fully released. Place parking brake control lever in fully applied position. Check position of parking brake equalizer lever with respect to frame cross-member. If lever touching frame, adjust control hand-to-equalizer lever cable by fully releasing parking brake control lever and rotating equalizer lever nut to adjust length of cable. Apply parking brake and check adjustment. If there is slack in brake cables when parking control handle is in fully released position, loosen locknut on equalizer rod, then tighten adjusting nut just enough to remove slack from cables. Tighten locknut securely. *CAUTION*—Adjust service brakes before attempting to adjust parking brake cable.

►***CAUTION: Make certain that rear brake shoes are not pulled away from anchors and that brakes do not drag with brake lever fully released.***

Ford F-1, 100 Truck—Place hand lever in full released position and check wheel cables for excessive slack. Adjust by loosening locknut and turning adjusting nut on front cable fitting at rear wheel cable equalizer connection. Cable should be tight enough to insure full application of rear wheel brakes, and loose enough for complete brake release when parking handle in "off" position. *CAUTION*—Adjust service brakes before attempting to adjust parking brake cable.

Ford F-2, F-3, F-250, F-350, P-350 Trucks—These models have independent brake on propeller shaft behind transmission. *See "Ford Truck Bendix Uni-Servo" for data.*

OVERHAUL

BLEEDING BRAKE SYSTEM: *See complete "Hydraulic Brake Servicing" for bleeding instructions.*

TROUBLE SHOOTING: *See "Hydraulic Brake Trouble Shooting" for complete data.*

BRAKE DRUM REPLACEMENT: Brake drums are "demountable" type (removable without disturbing wheel hub) on all models except Ford Pass. Car & Station Wagon **front wheels**. To remove brake drums take off nuts or remove capscrews or bolts holding drum on wheel hub or axle shaft flange. **Drum Regrinding Note**—When refinishing drums, inside diameter must not be increased more than .060" (not more than .030" removed from drum wall).

BRAKE SHOE REPLACEMENT: With wheels and brake drums removed, brake shoes are removed and replaced as follows:

Removal: Disconnect brake shoe return springs at anchor pin, remove hold-down cup, spring, and pin on each shoe. Disconnect hand brake cable at lever on rear wheel brake rear shoe. Pull shoes out at top to free wheel cylinder piston links, lift shoe assembly out, lift out hand brake strut and anti-rattle spring on rear wheel brakes. Disassemble shoes by removing adjusting screw spring (free spring by moving anchor pin end of shoes together) and lifting off adjusting screw assembly.

Relining Brake Shoes: Lining should be replaced when worn to point where rivet head less than 1/32" below surface of lining. Inspect shoes for distortion or looseness between rim and web. Clean shoe rim and remove all burrs or high spots before installing new lining. After riveting, new lining must be snug against shoe with not more than .005" separation midway between rivets.

►*BRAKE LINING NOTE*—Lining furnished in brake lining kits is ground in production and does not require grinding after installation.

Installation: Lubricate all points of contact between brake shoes and other brake parts with Lubriplate. Assemble both brake shoes with adjusting screw and spring (see illustration). On rear wheel brakes, assemble parking brake lever on rear (secondary) shoe and install link. Install shoe assembly on backing plate, install hold-down cups and springs, install return spring. Install drums and adjust brakes.

OVERHAUL: Master Cylinder & Wheel Cylinders. *See "Hydraulic Brake Servicing" for complete data.*

►***BRAKE OVERHAUL NOTE: When overhauling front wheel brake assemblies with eccentric cam adjustment, it is necessary to remove eccentric spring before removing shoe. Replace spring after shoe installed.***

FORD TRUCK SELF-CENTERING

Ford Truck, 500, 600, 700, 750 Series (1953-55). Rear Brakes Only.

►***FRONT WHEEL BRAKE CAUTION: Different front wheel brakes used on these models as follows:***
500 & 600 Series—Ford-Bendix "Uni-Servo."
700 & 750 Series—Ford-Lockheed Double Anchor

►***POWER BRAKE NOTE:*** "Hydrovac" or "Midland" Standard or Optional on these trucks.

►***1955 500 & 600 SERIES TRUCK REAR WHEEL BRAKE CYLINDER LEAKAGE CORRECTION (Due to Excessive Depth of Counterbore):*** To correct, install **two** 91A-2152 gaskets between brake pipe connector and wheel cylinder body.

►***1953-55 500 SERIES & T-700 TRUCK REAR WHEEL BRAKE CYLINDER LEAKAGE CORRECTION:*** New brake cylinder assemblies and a conversion kit are available to correct above condition. The B5T-2222-A Conversion Kit is used to convert brake cylinders now in service. New rear brake cylinder assembly parts are as follows:

Part	Application	Old Part No.	New Part No.
Brake Cyl. Assy. Upper		B4T-2261-A	B5T-2261-A
Brake Cyl. Assy. Lower		B4T-2262-A	B5T-2262-A
Link			B5T-2042-A
Kit, Conversion	Both		B5T-2222-A

►***500 & 600 SERIES TRUCK ERRATIC BRAKE OPERATION CORRECTION (Due to Improper Return of Rear Brake Shoes After Application):*** Clearance between brake shoes and brake carrier plate at hold-down bolt should be .025". Adjust hold-down bolt to obtain proper clearance. *NOTE*—Gauge surface is machined boss on carrier plate which is in line with hold-down bolt.

►***1955 MASTER CYLINDER PUSHROD INSTALLATION CAUTION:*** On F, B-500 Trucks master cylinder pushrod and clevis pin are installed in upper hole

CONTINUED ON NEXT PAGE

FORD TRUCK SELF-CENTERING (C ntinu d)

in brake pedal on trucks with conventional brakes and in lower hole on trucks with booster brakes; on other trucks pushrod and clevis pin are installed in lower hole in brake pedal.

DESCRIPTION: Two-cylinder, two-shoe, four-anchor type hydraulic brakes. Each shoe is anchored at each end and linked to wheel cylinder at each end so that all shoes are self-energizing for both forward and reverse motion. All shoes are radially self-centering. ***CAUTION—TWO differently adjusted brake designs used. See Adjustment data.***

ADJUSTMENT: Make adjustments with brake drums at normal temperature and with wheels either jacked up or contacting road (if wheels on road so they cannot be turned to check for drag, make this check by striking drum with a hammer—sound will be deadened if shoes contacting drum). ***ADJUST EACH TYPE AS FOLLOWS:***

500 & 600 Series Adjustment: Proceed as follows:

Minor Adjustment (For Wear)—Remove two adjusting hole covers on backing plate (adjacent to right hand anchor bolt at each wheel cylinder), insert tool through slot and turn notched adjusting screw or "star wheel" until lining drags on drum, then back off adjusting screw until wheel is free of drag. Depress brake pedal to centralize shoes and recheck wheels. Adjust each shoe in each wheel in this manner.

Major Adjustment (Relined Brakes)—Proceed as in Minor Adjustment (above), then adjust brake shoe hold-down bolt for clearance of .025" from brake shoe to gauge surface on plate (gauge surface is machined boss on brake plate in line with hold-down bolt).

700 & 750 Series Truck Adjustment: Remove the two adjusting hole covers on backing plate (adjacent to right hand anchor bolt at each wheel cylinder), use Allen wrench inserted through hole to turn adjusting worm in direction of FORWARD wheel rotation to move brake shoe out until it drags on drum, then turn wrench in opposite direction until drag is relieved. Depress brake pedal to center brake shoes in drum, then turn wrench one additional turn to provide working clearance. Adjust each shoe in each wheel in this manner. This is the only adjustment required.

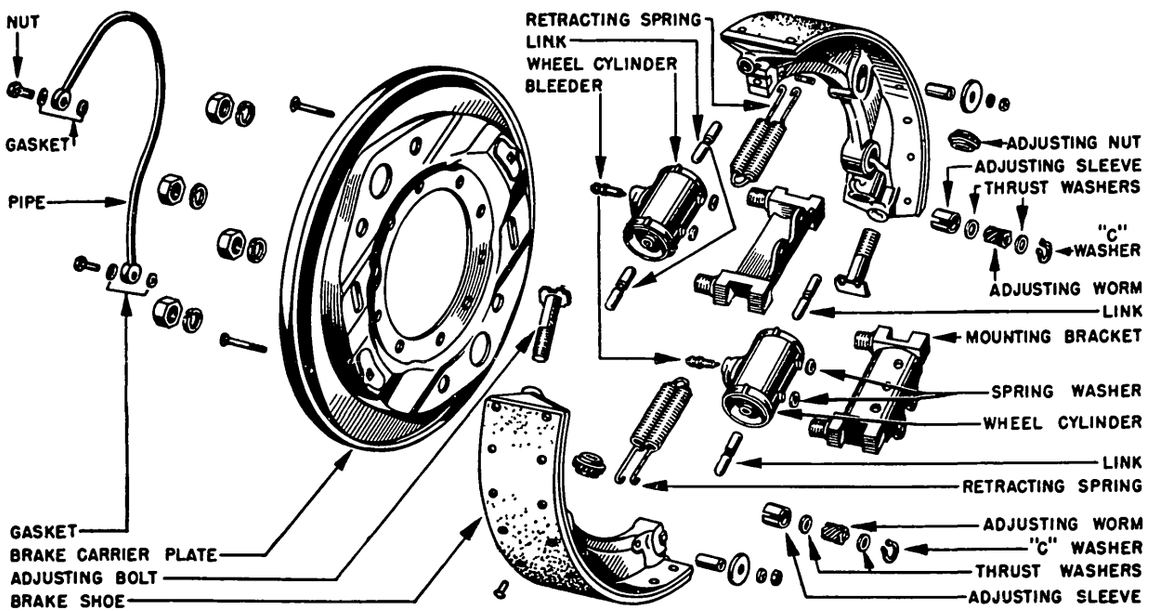
Brake Pedal Adjustment: Pedal must have at least 3/16" but not more than 3/8", free travel measured at pedal pad before master cylinder piston begins to move. To adjust, loosen locknut on brake pedal to master cylinder pushrod, rotate rod until free travel within limits, tighten locknut.

Parking Brake Adjustment: On cable controlled parking brakes, move parking brake lever to fully released position. On transmission mounted parking brake levers, set lever to first notch. Observe position of cam to make sure flat portion is resting on brake band bracket. If cam not flat with bracket, remove clevis pin from upper part of cam, then adjust clevis rod to allow flat portion of cam to rest on brake band bracket. Install clevis pin and cotter pin. Remove lock wire from anchor adjusting screw, turn adjusting screw clockwise until clearance of .010" is established between brake lining and brake drum at anchor bracket. Loosen lock nut on adjusting screw for lower half of brake band, adjust screw to establish .010" between brake lining and drum at lower half of brake band. Tighten lock nut. Turn upper band adjusting nut until .010" clearance established between upper half of band and drum. Be sure to install lock wire in anchor adjusting screw.

DISASSEMBLY: NOTE—Brakes can be serviced without removing hubs or disturbing wheel bearings. Remove wheels, then screws holding drum to hub (mark drum and hub to insure correct assembly). ***CAUTION—If wheel cylinder connecting tubes and bleeder screws removed, mark ports to which tubes attached to assure correct reassembly.*** Disassemble brakes as follows:

500 & 600 Series—Remove retracting springs with Tool 2035-N. Remove brake shoe hold-down screw, then brake shoes.

700 & 750 Series—Remove brake shoe retracting springs by removing shoe guide bolt nut, lockwasher, and washer holding shoe in place, then remove shoes. To remove adjusting mechanism, rotate adjusting worm, threading it free of worm wheel. Remove worm retainer snap ring from shoe, then end thrust washers, sleeve and worm, worm wheel.



REASSEMBLY: (NOTE—For best results, new shoe and lining assemblies should have the lining of correct thickness ground to proper radius concentric with brake drum. If linings are not ground, it may be necessary to readjust the lining after linings have "worn in." Make sure no nicks or burrs are on shoe edge at point of contact with brake plate).

500 & 600 Series—Place light film of Lubriplate on primary (sliding pivot) anchor and shoe bearing surfaces on brake plate. Position brake shoes in anchors and in slotted ends of wheel cylinder. Apply light film of Lubriplate to hold-down screw, then install hold-down screw, washer and nut. Tighten hold-down nut until there is a clearance of .025" between center (of three) machined bosses on plate and edge of shoe. This clearance necessary to hold shoe parallel to drum or prevent shoe from binding against outer machined bosses. Install retracting springs (Tool 2035N), wheel cylinder brake pipe, drum assembly, wheel. Adjust brakes.

700 & 750 Series—(NOTE—***Assemble all parts dry.***) Assemble adjusting mechanism (thrust washers, sleeve, worm and worm wheel). The sleeve slot must face worm wheel to allow worm and wheel to mesh. Install worm retainer snap ring into groove in shoe. Install adjusting worm in worm wheel, and adjust to full "OFF" position. ***(CAUTION***—Curved side of pad on adjusting screw must be in proper position to permit it to rock on anchor block when shoes are installed on backing plate). Install one shoe on backing plate making sure adjusting worm is aligned with the adjustment slot in backing plate. (CAUTION—It is possible to install shoe in reverse position. If so installed, brake **cannot** be adjusted). Install shoe guide sleeve on guide bolt and assemble guide washer, lockwasher and locknut, tighten locknut. Repeat above procedure for other shoe. Install shoe retracting springs. Adjust brakes.

BLEEDING BRAKE SYSTEM: Bleed **top** wheel cylinder **first**, then lower. If power unit used, unit must be bled before wheel cylinders, with engine off and no vacuum in power unit system. ***See "Hydraulic Brake Servicing" preceding for bleeding data.***

TROUBLE SHOOTING: ***See "Hydraulic Brake Trouble Shooting" preceding for data.***

1948-51 HUDSON VACUMOTIVE DRIVE

Hudson 6 & 8, All Models (1948-51) Optl.

▷DRIVE-MASTER & SUPERMATIC DRIVE NOTE: Vacumotive Drive is incorporated as a part of Drive-Master and Supermatic Drive installations and when used with these transmissions is similar to the separate unit below except that an additional "Throttle Lock" unit is used which is mounted on the Vacumotive power cylinder.

See "Hudson Drive-Master" in Transmission Section for Throttle Lock data.

▷DRIVE-MASTER FUSE CHANGE: 10 ampere fuse used on first cars should be replaced with 15 ampere fuse as used on later cars. This fuse located in lead to control switch (1948), on back of switch (1949-50).

DESCRIPTION & OPERATION: Vacumotive Drive on these cars is similar to design used on previous models except for relocation of units and linkage (see illustration) and new type wiring harness with plug connectors at each unit (plug-and-socket connectors eliminate possibility of wrong connections).

ADJUSTMENT: *Before adjusting Vacumotive Drive units, make all "Engine Adjustments" listed below, then make "Vacumotive Drive Adjustments in order and exactly as listed:*

Engine Adjustments: Make sure that engine properly tuned up, and clutch linkage adjusted, by checking and adjusting following points:

Engine Idle Speed—Must be set at 580-600 RPM. hot or slow idle speed. NOTE—Check with Vacumotive Drive control button on instrument panel "on".

Clutch Pedal Clearance—Clearance between underside of toeboard and upper (rear) face of clutch pedal shank must be 1½" with clutch engaged (to insure full disengagement when pedal depressed). Adjust by loosening locknut and turning clevis at lower end of connector link.

NOTE—On 1950 Pacemaker, and all 1951 models, clevis yoke has two holes to provide for greater range of adjustment. Clevis pin can be installed in either hole.

Starter Switch Note—On Drive-Master and Supermatic Drive cars, Starter should be operative when clutch pedal depressed to point not less than 2" from toeboard. To check, hold starter button in, turn on ignition, slowly press in on clutch pedal, and note point at which starter begins to operate.

Accelerator Linkage—See that entire linkage (both accelerator and vacumotive drive system) works freely without binding. Lubricate all linkage joints and bellcranks and correct any binding. Check system by opening throttle slightly and releasing very slowly with control switch "off". Accelerator bellcrank arm should come back solidly against its stop.

Accelerator Pedal Adjustment—Adjust accelerator pedal rod (two nuts on forward end of rod at accelerator bellcrank) for correct travel on each model as follows:

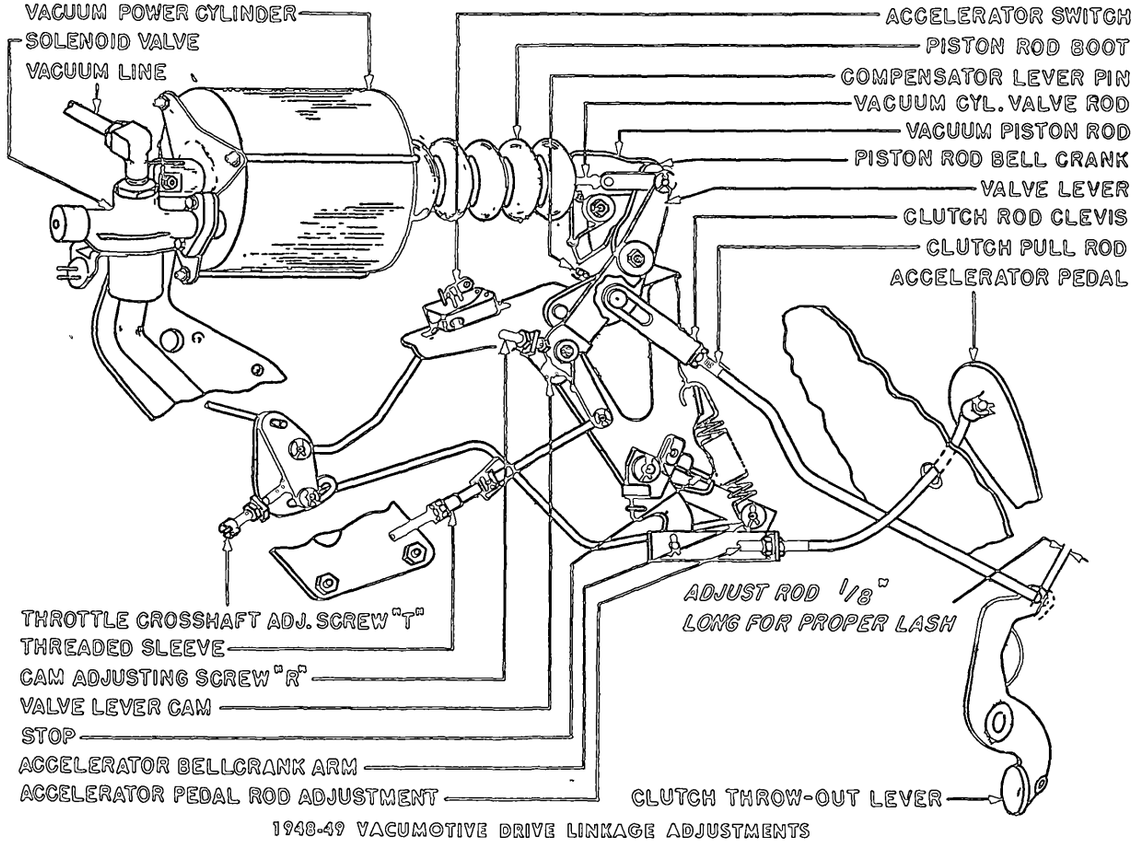
1948-49 Models—With accelerator pedal released, distance from underside of pedal tip to floor mat should be 4 31/32", and throttle valves must be wide open when accelerator pedal fully depressed.

1950-51 Pacemaker (without Overdrive)—Adjust rod so that throttle valve is wide open at point just before accelerator pedal tip strikes the floor mat.

1950-51 Models with Overdrive or Drive-Master—Adjust rod so that carburetor throttle valves are in wide open position when pedal depressed to point just before it contacts overdrive kick-down switch plunger on toeboard (or pedal stop located at same point on cars without overdrive).

Accelerator Switch Adjustment—With accelerator pedal released, see that accelerator bellcrank against stop (see illustration), loosen accelerator switch mounting screws and position switch on mounting bracket so that switch arm is solidly against stop on switch, tighten the mounting screws. Press down on accelerator, release slowly, check to see that accelerator switch lever and bell crank lever solidly contact their stops.

Vacumotive Drive Adjustments: Set brakes (to prevent car moving while making adjustments), place shift lever in neutral position, depress clutch pedal and start engine, hold clutch pedal down until Vacumotive Drive takes over and holds clutch disengaged. Run engine until normal operating temperature reached and engine idles at 580-600 RPM., then make following adjustments in order given:



▷*CAUTION—Compensator lever must be in upward position (starting position) when making adjustments. Lever will be correctly positioned for each adjustment if adjustments made exactly as follows:*

1) Piston Travel—With engine idling to provide vacuum, check piston position by pressing in on valve lever and then releasing lever. Piston should be ½" back from extreme forward position and should return to this position when lever released. Adjust by loosening locknut and turning threaded sleeve (see illustration for location on 1948-49 cars —on 1950-51 cars with redesigned threaded sleeve rod, adjustment is located on rear end of rod in back of cam lever).

▷*NOTE*—Pushing lever down to normal running position will cause piston to move forward (if piston moves backward, eccentric is upside down).

2) Piston Valve Rod Check—The center line of the pin (in end of valve operating link at valve lever) should line up with center line of piston rod pivot bolt. The valve rod can be adjusted by loosening locknut and turning valve rod in or out of the threaded trunnion. NOTE—This adjustment is made in production and normally should not be required unless rod adjustment has been disturbed.

3) Clutch Pull Rod Adjustment. Stop engine. With engine not running, pull vacuum piston rod out fully (to rear), check clutch pull-rod for required ⅛" free play or lash by pulling rod forward and up. With correct lash, forward end of pull-rod clevis will just contact compensator lever pin. Adjust by loos-

1948-49 VACUMOTIVE DRIVE LINKAGE ADJUSTMENTS

CONTINUED ON NEXT PAGE

HUDSON VACUMOTIVE DRIVE 1948-51 (Continued)

ening locknut and adjusting clevis on forward end of pull-rod.

4) Throttle Adjustment—Back out cam adjusting screw until there is ½" gap between cam and screw. Depress clutch pedal (IMPORTANT) and start engine. Hold clutch pedal down until clutch control unit cylinder takes up the load. DO NOT RACE THE ENGINE. Put transmission in 2nd gear and release the brakes. Slowly rotate the throttle bell crank until clutch drags. Adjust the throttle cross-shaft adjusting screw "T" (see Note below) until there is a slight increase in engine speed (to 625-750 RPM) when the car begins to move forward.

Adjusting Screw Note—See illustration for location of this "T" adjusting screw on all models except Pacemaker. On Pacemaker models, screw is located on cylinder head.

▷*CAUTION—The above adjustment should be made with the compensator in the starting position, trip lever pin forward or away from valve lever.*

5) Cam adjusting Screw (Cushion Point)—Stop the engine. Depress clutch pedal manually and start engine. Engage transmission Second Gear, set brakes firmly to prevent car moving. Turn Cam Adjusting Screw "R" in fully, press valve lever cam forward against the cam adjusting screw and back screw out until engine stalls. NOTE—Final adjustment of this screw is made during "Fast Start" part of Final Road Test following.

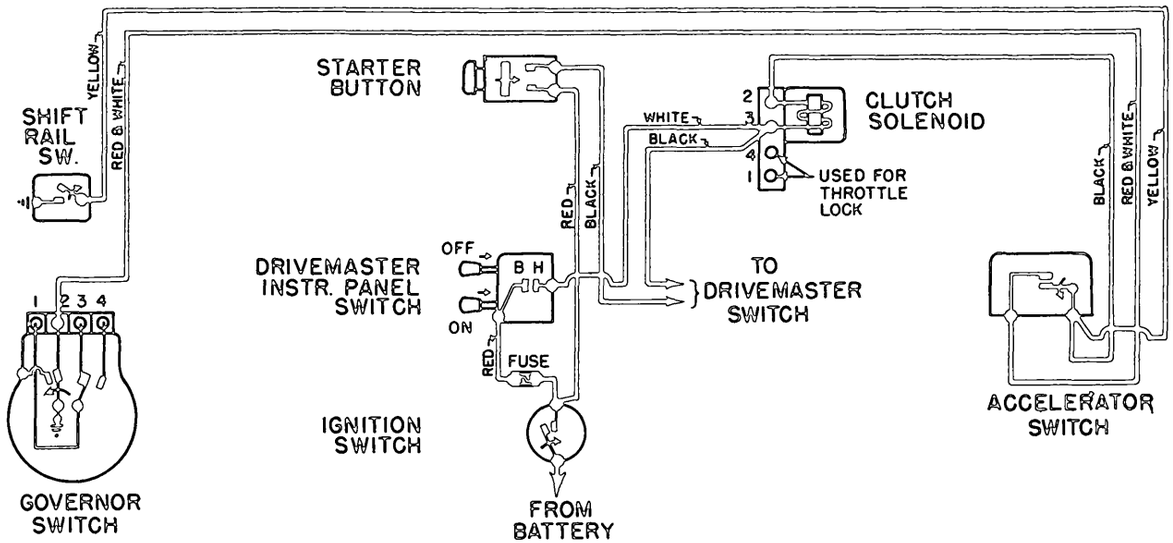
▷*NEW TYPE CUSHION POINT SCREW:* To provide better contact area. New type Part No. 302098 has screw driver slot in small end, and larger hexagon head. New screw in installed so that the hexagon head contacts the cam, instead of the small end of bolt as used previously.

6) Final Road Test—Check performance by road testing car and make necessary re-adjustments for Slow & Fast Starts as follows:

Slow Start—Start car up normally except that accelerator pedal should be depressed very slowly to put car in motion. Engine speed should increase slightly just before car starts to move. Adjust throttle cross-shaft adjusting screw "T" as necessary (see adjustment 4 above).

Fast Start—Start car up normally except that accelerator pedal should be rapidly pressed halfway to floor. Car should move forward smoothly without excessive clutch slippage. Turn cam adjusting screw "R" in or out as necessary (see adjustment 5 above) but do not turn screw in more than 2 turns from original (5) setting.

▷*CAUTION—Do not turn screw in more than 2 turns from initial setting (5 above) when making this final adjustment.*



LUBRICATION: Linkage and power cylinder should be lubricated at regular intervals as follows:

1000 Miles—Oil all pivot points in Vacumotive Clutch Mechanism with light engine oil.

CAUTION—Make certain that several drops of oil placed in piston rod bellcrank oil hole.

10000 Miles—Remove pipe plug in end of power cylinder, spray one oz. of Hudson Shock Absorber fluid through this hole.

TESTING CONTROL UNITS: Use a test lamp to check circuits through switches and other electrical units. Make tests as follows:

VACUMOTIVE DRIVE WIRING DIAGRAM

Wiring—Wire connections at control units are made by means of plug-and-socket connectors to eliminate possibility of wrong connections. See 1947 Vacumotive Drive for wiring diagram.

Vacumotive Drive Switch—With ignition switch on, and vacumotive drive switch turned to the on (right) position, ground one test lamp lead and touch other lead to #1 (Brown wire) switch terminal. Lamp should light. If lamp does not light, switch is open.

Accelerator Switch—Remove connector plug on switch. Connect jumper wire between #2 prong (Yellow wire) on switch and ground. Connect one test lamp lead to ungrounded battery terminal, touch other test lamp lead to #1 prong (Red wire) on switch. Lamp should light. Move lever 10° from stop, lamp should go out. Move test lamp lead to #3 prong (Black wire) on switch. Lamp should light with switch lever against stop. Move lever approximately 2/3 of travel from stop, lamp should go out.

Shift Rail Switch—Connect one test lamp lead to ungrounded terminal on battery, connect other lead to #2 socket (Yellow wire) of cable at accelerator switch. Move gearshift lever to High Gear position. Lamp should not be lighted. Move gearshift lever to other gear positions. Lamp should be lighted in all positions except High Gear.

Valve Solenoid—Remove connector socket. Connect jumper between solenoid #2 prong (Black wire) and ground. Connect one test lamp lead to ungrounded terminal of battery, connect other lamp lead to #1 prong (Brown wire) on solenoid. Solenoid should operate and lamp should light with dim glow.

Governor—Can be checked by noting performance during road test. See that Red wire of Vacumotive Drive harness connected to governor terminal (or to #2 prong on governor on Drive-Master cars). Drive car on road and accelerate to 30 MPH., then release accelerator pedal and allow car to coast down in high gear. Clutch should release at 16-21 MPH. (noted by resting foot lightly on pedal).

SERVICING: All Vacumotive Drive units should be serviced by replacement if tests indicate that they are defective. Do not attempt to repair units.

REMOVAL & INSTALLATION: *Power Cylinder and Mounting Bracket are removed and installed separately*

Power Cylinder: Removal. Disconnect air intake pipe and vacuum line at solenoid valve. Remove valve lever eccentric bushing nut, pull bellcrank lever out to allow clearance for removal of valve rod link. Take out cotter pin in pivot bolt at upper end of valve lever, disconnect lever link from bellcrank, remove pivot bolt. Take out two Throttle Lock bracket attaching screws at clutch power unit cylinder, disconnect throttle lock vacuum line. Take out two bolts attaching solenoid valve to clutch power unit cylinder, remove solenoid (and throttle lock solenoid if used) as a unit. Remove palnut and regular nut and remove bolt attaching clutch power cylinder to mounting bracket, remove cylinder as a unit with rod, and piston valve rod and link.

Installation—Install power cylinder by reversing removal procedure given above. Adjust.

▷*CAUTION—Make certain that solenoid ground wire (pigtail lead at rear of solenoid case) not broken.*

Mounting Bracket: Removal. Remove two bolts attaching rear end of bracket to throttle bellcrank bracket. Disconnect air intake pipe and vacuum line at clutch power unit solenoid. Remove two bolts attaching mounting bracket to support bracket, and one bolt attaching mounting bracket to throttle cross rod mounting bracket. Remove palnut and regular nut and remove bolt attaching clutch power cylinder to mounting bracket. Disconnect accelerator switch operating rod at accelerator lever. Pull complete bracket toward fender for clearance and remove cotter pin, washer, spacer washers, and spring washer attaching bellcrank support pin to mounting bracket. Slide bracket out toward engine and remove from car.

Installation—Install mounting bracket by reversing removal procedure as given above. After installation completed, check to make certain that throttle cross rod not binding in mounting bracket.

1946-50 PACKARD ELECTROMATIC

"2100" Series, All Models (1946-47)
"2200" & "2200-9" Series, All Models (1948-49)
"2300" & "2300-5" Series, All Models (1949-50)
Not used on Ultramatic Drive Cars.

▷NEW TYPE CONTROL VALVE SEAT: Part No. 410505. Use to replace earlier type seats which have loosened up and moved out of position. This seat has oversize diameter and is pressed in.
CAUTION—Clutch control valves calibrated for each particular model. Use only type specified for that model when replacing unit.

▷NEW CLUTCH PEDAL TO RELAY LEVER LINK: Part No. 418534 (superseding solid non-adjustable type). Use to provide for full clutch pedal retraction. When installing this new link, adjust length so that distance between outer ends of slotted holes measures 9 25/32", check clutch pedal action. If pedal does not fully retract, lengthen link until proper pedal retraction secured.

DESCRIPTION & OPERATION: Electromatic clutch on these cars is similar to design used on previous models except for simplified control mechanism (see illustration) and operates as follows:

Power Cylinder: Diaphragm type mounted on left side of engine and linked to clutch relay lever by pulley and cable mechanism (pulley mounted on lever, free end of cable anchored to bracket on starter). Rear chamber in cylinder is open to atmospheric pressure (through air cleaner) at all times. Front chamber is controlled by Control Valve and is connected to manifold vacuum (for clutch disengagement) or to the atmospheric pressure (for clutch engagement).

Control Valve Assembly: Consists of a hollow piston type valve controlling air-and-vacuum admission to forward chamber of power cylinder. A regulating diaphragm unit and accelerating linkage connection control the valve piston through a fulcrum lever linkage to provide correct clutch engagement under all operating conditions.

Lockout Solenoid Valve: This valve controls the vacuum line between the manifold and the Electromatic Clutch so that electromatic clutch is operative only with valve open. Valve is spring-loaded so that it is closed when solenoid is not energized (Lockout Switch "off"). Pressing the lockout switch (switch "on") energizes the solenoid and opens the valve whenever the circuit is completed to ground through the Direct Speed Switch, Accelerator Switch or Governor.

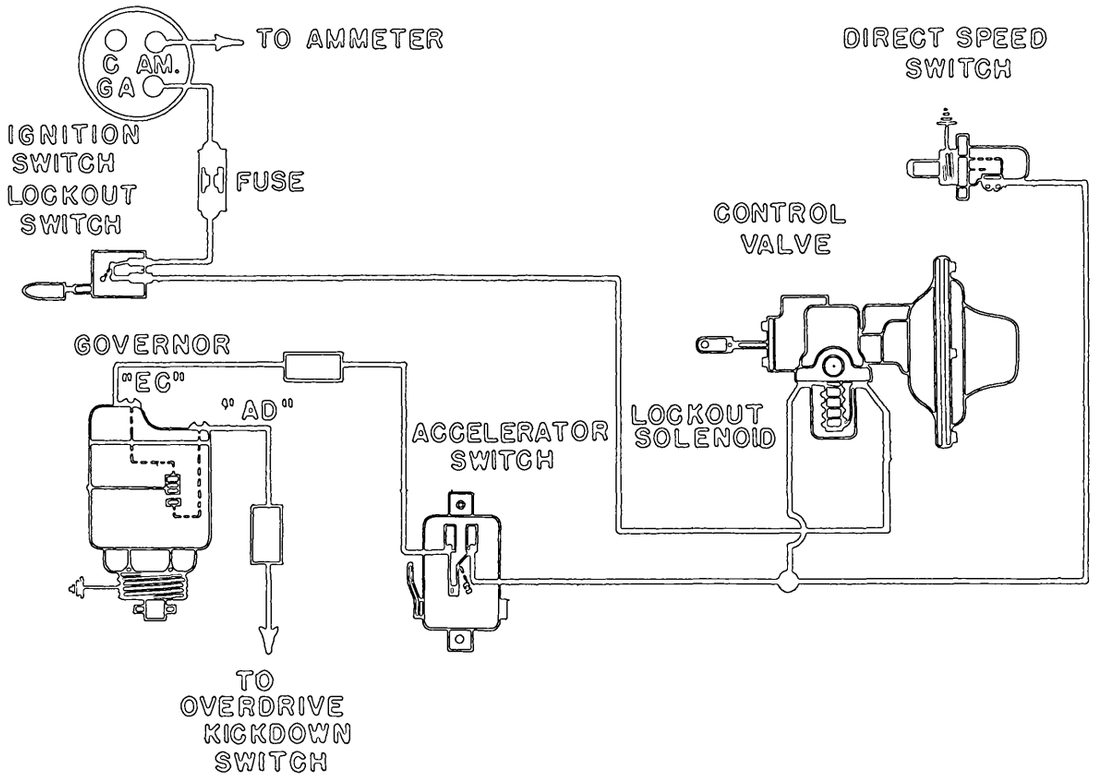
Direct Speed Switch—Mounted on bracket to rear of power cylinder and actuated by idler lever of transmission shift linkage. Switch contacts are open with transmission in high gear (Electromatic clutch inoperative unless circuit completed by other controls) and are closed with transmission in neutral or any other gear (electromatic clutch operative regardless of position of any other controls).

Accelerator Switch—Mounted on dash and connected to accelerator pedal linkage. This switch is connected in series with governor and is effective only at low speeds (below governor cut-out point). Switch contacts are closed only with accelerator pedal released and prevents clutch disengagement with accelerator pedal depressed and engine running at more than idle speed (with transmission in high gear—when any other gear engaged, clutch operation is controlled by Direct Speed Switch

Governor—Mounted at rear of Overdrive. "EC" contacts control electromatic clutch operation ("AD" contacts control Overdrive) and are closed at car speeds below 22 MPH. completing lockout solenoid circuit so that electromatic clutch is operative (accelerator switch contacts must also be closed for clutch disengagement—see above). At speeds above 22 MPH., governor contacts remain open so that clutch does not disengage when accelerator pedal is released (with transmission in high gear—when any other gear engaged, clutch operation is controlled by Direct Speed Switch (above).

ADJUSTMENT: *CAUTION—Make all adjustments in order and exactly as follows:*

1) Clutch Pedal Free Play—Check and adjust free play to 1½" (see car model pages for instructions).



▷Pedal Link Change—See "New Clutch pedal to Relay Lever Link" data above if clutch pedal does not retract fully.

2) Power Cylinder Operating Cable—Check adjustment by depressing clutch pedal to toeboard (engine must be running and Electromatic clutch "on"). Pressure required to depress pedal should be very light to within ½" of toeboard, and pressure for final ½" movement of pedal should be same as required with Electromatic Clutch "off". If this ½" final travel with increased pressure not noted, adjust cable by backing off adjusting nut at anchor bracket on starter (see Note), tighten second nut on cable fitting, recheck operation.

▷Adjusting Note—If range of adjustment on cable fitting insufficient, grind off face of cable eye on bracket (Eight & Super Eight), shift bracket on starter (Custom Eight).

3) Accelerator Linkage—Adjust to remove excessive free play in linkage between accelerator pedal and carburetor throttle. Adjust carburetor-to-cross shaft link clevis for 1/16" clearance between throttle operating lever and stop on electromatic control valve bracket with carburetor throttle stopscrew against stop with fast idle cam in slow or hot idle position. Adjust accelerator-to-electromatic clutch operating lever rod (adjusting nut at control valve end of rod) so that pin enters hole in operating lever. Check to make certain that the valve operating lever rotates clockwise to the wide-open throttle position when accelerator pedal is depressed to point where accelerator bellcrank contacts overdrive kick-down switch plunger.

4) Control Valve Engine Speed Screw & Operating Rod—Operating rod requires adjustment only if engine speed screw adjustment not sufficient.

1946-50 ELECTROMATIC CLUTCH WIRING DIAGRAM

CONTINUED ON NEXT PAGE

1946-50 PACKARD ELECTROMATIC (C ntinu d)

Engine Speed Screw—Engine must be thoroughly warmed up and idling at hot or slow idle speed for this adjustment. With engine idling, place car on level floor, engage transmission Second Gear. Adjust engine speed screw so that car will just move when valve operating lever is brought up against the engine speed screw. If screw does not have sufficient range for correct adjustment (turns completely in or out before correct setting secured), operating rod as directed below. Normal gap between engine speed screw and operating lever should be approximately 7/32".

Operating Rod—Engine must be warmed up and idling at hot or slow idle speed for this adjustment. Turn engine speed adjusting screw in to midpoint of travel, disconnect valve rod link at valve operating lever, hold throttle operating lever against stop on bracket. Position valve operating lever so that clearance between lever and stop is ⅛" and **hold lever in this position.** Move valve rod in slowly until power cylinder operating cable just starts to move out and hold valve rod in this position. Adjust clevis on forward end of valve rod until operating link can be engaged, secure link with spring clip lock. Then check and adjust Engine Speed Screw.

5) Direct Speed Switch—Disconnect lead at switch terminal, connect test light and battery between this terminal and ground. Place gear shift lever in High Gear position. **Lamp should not light.** Move gearshift lever toward neutral. **Lamp should light** when lost motion in linkage is taken up but before transmission shifter fork moves out of detent. Adjust switch by loosening clamp bolt and shifting bracket on mounting stud until correct performance secured.

6) Accelerator Switch—Disconnect both leads at switch terminals, ground one terminal, connect test lamp and battery to other terminal. With accelerator pedal released, **lamp should be lighted.** Depress accelerator pedal slowly until valve operating lever just contacts engine speed screw, **lamp should go out at this point.** If lamp remains lighted, loosen locknut and turn adjusting screw on face of switch until lamp goes out. Release accelerator pedal, lamp should light. Recheck setting, tighten adjusting screw locknut.

7) Governor—No adjustment provided. Governor should be replaced if operation unsatisfactory. See Testing of Control Switches (below).

8) Road Test & Fast Start at Full Throttle Setting: After preceding adjustments completed, road test car and make necessary adjustments for special fast starting with full throttle performance as follows:

Fast Start-with-Full Throttle Setting—Check performance by making fast starts (full throttle) in second gear. Clutch should engage as rapidly as possible without causing engine to stumble. To adjust, turn valve rod stop screw (on rear face of control valve diaphragm cover) out until screw head extends 1¼" from diaphragm cover (will cause very rapid clutch engagement on fast starts), then turn screw in or clockwise ¼ turn at a time and repeat tests until satisfactory clutch engagement is secured without excessive slippage.

►*CAUTION—Do not allow clutch to become overheated through excessive slippage while adjusting.*

Final Road Test Check—Test electromatic clutch operation under normal driving conditions. Readjust as required if clutch slippage is excessive or if engagement too severe under driving conditions.

TESTING ELECTRICAL UNITS: To check switches and other control units, use test lamp as directed

►*CAUTION—Check Electromatic Clutch Fuse first (in line between ignition switch and lockout switch) before making additional tests.*

Direct Speed Switch: See 5) under Adjustm't (above).

Accelerator Switch: See 6) under Adjustm't (above).

Lockout Switch: Disconnect red wire at Lockout Solenoid, connect one test lamp lead to this wire, ground other test lamp lead. Turn ignition switch "on". Press Lockout Switch knob for alternate "on" and "off" positions. Lamp should light with switch on, and should not be lighted with switch off. If lamp does not light with switch on, check for blown fuse and check line between ignition switch and lockout switch for open-circuits, replace switch. If lamp does not go out with switch off, switch is shorted and should be replaced.

Lockout Solenoid: Disconnect both wires at Lockout Solenoid terminals. Ground one terminal. Connect one test lamp lead to other terminal, connect other test lamp lead to ungrounded terminal of battery. Lamp should light. If lamp does not light, solenoid winding is open.

Governor: Connect one test lamp lead to ungrounded terminal of battery. Connect other test lamp lead to each governor terminal in turn. Lamp should light when connected to "EC" terminal (electromatic clutch contacts), and should not light when connected to "AD" terminal (Overdrive contacts).

SERVICING: Correct deficiencies as follows:

Accelerator & Throttle Linkage: To permit accelerator linkage to return to its closed throttle position as quickly as possible after release of accelerator pedal, apply Lubriplate to all friction surfaces *except the valve operating rod* (after cleaning and inspecting for worn parts). Lubriplate on valve operating rod would cause "gumming" between rod and valve guide sleeves.

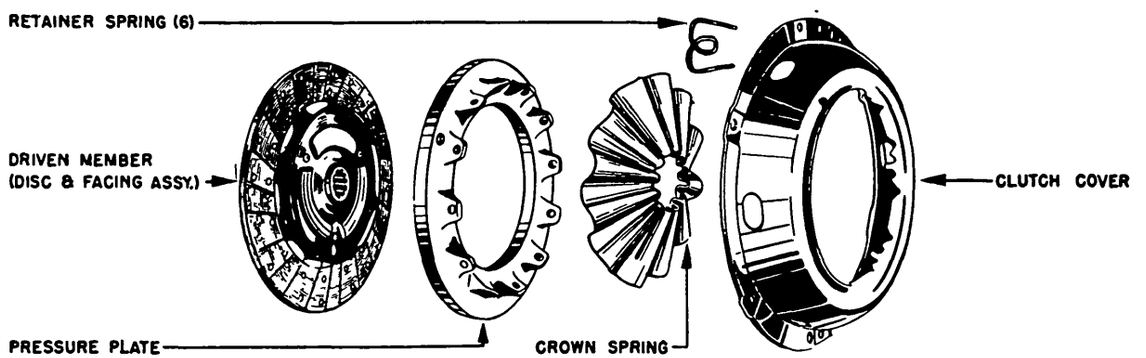
Control Valve Air Cleaner: *Do not oil or wash.* Cotton element is not replaceable. Air cleaner should be replaced when clogged with accumulated dirt.

Hose & Steel Lines: Replace any deteriorated, collapsed, or damaged rubber hose. Check all tubing connections for tightness and inspect lines for kinks or breaks. Replace damaged tubing.

Power Cylinder: Check to see that joint between the two shells of power cylinder is tight and cable connection threads are not stripped. Replace diaphragm, if damaged.

Clutch Control Valve: *(CAUTION—Control valves are carefully calibrated for particular models on which they are installed. Never install a clutch control valve on a model other than that for which it was intended).* If Electromatic Clutch performance remains rough and erratic after all adjustments have been properly made, it is probable that the control valve is at fault. It should be removed, cleaned, inspected, and replaced if necessary.

BUICK (OWN) CROWN SPRING



1946-55 Series 40 (Synchro-mesh Cars)
1946-52 Series 50 (Synchro-mesh Cars)

►CHANGES, CAUTIONS, CORRECTIONS

►**Excessive Pedal Pressure and Noisy Clutch Disengagement Correction:** If the clutch pedal pressure required to disengage clutch exceeds 35 lbs., check for dry release linkage and apply small amount of Lubriplate to clutch spring disc at points where it contacts cover. Check clutch release bearing support for correct assembly, brush Lubriplate on bearing surface between bearing retainer and support.

►**Clutch Dragging Correction:** If drag not caused by pedal free travel adjustment, remove clutch housing lower cover, hold pedal in disengaged position and check for clearance between crown spring disc and edge of cover with feeler gauge. Spring must contact cover at all points (clutch will not disengage

CONTINUED ON NEXT PA E

BUICK "CROWN SPRING" CLUTCH

BUICK (CROWN SPRING) (CONTINUED)

properly unless firm bearing secured at all points). To correct this condition, disassemble clutch, place cover assembly on surface plate, check height of six ears to which retainer springs are hooked and bend ears so that distance from surface plate to upper edge of each ear is exactly 1⅝". Replace retainer springs if they are weak or distorted. CAUTION—Replace springs as complete set only (necessary to assure even spring tension).

DESCRIPTION: Single plate, dry disc, of new design with corrugated spring disc which replaces both pressure springs and release levers used on former clutch. Corrugations on disc engage ears on inner rim of clutch cover and lugs on pressure plate. Disc pivots on cover plate ears when it is flexed to release clutch, relieving pressure on pressure plate which is then pulled away from driven member by hairpin type retainer springs which pass through holes in pressure plate lugs and are hooked over cover ears.

REMOVAL: *See "Clutch" on car model page.*

DISASSEMBLY: Mark pressure plate, spring disc and cover. Use tool J-1039-2 to unhook retainer springs from the clutch cover ears working springs slightly toward center to permit tool engagement (do not hammer on tool which will distort cover), lift clutch cover off. Unhook retainer springs from spring disc by working one leg of each spring in through pressure plate lug toward center of clutch and other leg out, lift off spring disc, remove retainer springs from pressure plate lugs.

Clutch Cover Inspection—Check height of spring retainer ears by placing cover on flat surface and measuring from surface to top surface of each ear. Distance should be 1 5/8". Correct by bending the ears *(CAUTION*—use care not to crack or distort cover). Replace cover if cracked or distorted.

Crown Spring Inspection—Check for excessive flattening of the spring due to taking on a permanent set, by placing spring on flat surface and measuring height of top surface of spring at inner rim. Normal height is 1 13/16" and height should not be less than 1 11/16"

REASSEMBLY: Install the retainer springs in pressure plate lugs with curved legs of springs up toward spring disc (push one leg of each spring in toward center of clutch and position the other spring leg that it is just entered in hole in lug). Apply 'Lubriplate' lightly on spring disc at points where it contacts pressure plate and retainer springs (excess will ruin clutch facings), place spring disc on pressure plate, maneuver retainer spring loops over disc by turning springs so that they are properly aligned. Install cover, use special tools to engage retainer spring loops on cover ears. Make certain that marks on pressure plate, spring disc, and cover are lined up. This completes clutch assembly (no release lever adjustment, etc. required).

DRIVEN MEMBER: Both Borg & Beck and Long Driven Members used. Driven members serviced as an assembly and parts not furnished separately. When installing driven members, see that large washer or oil baffle is toward transmission.

See Borg & Beck and Long "CF" clutches for complete driven member data.

BUICK (OWN) SINGLE PLATE

1946-48 Series 70 (Synchro-mesh Cars)
1953-55 Series 50 (Synchro-mesh Cars)
1954-55 Series 60 (Synchro-mesh Cars)

▷CHANGES, CAUTIONS, CORRECTIONS

▷Excessive Pedal Pressure and Noisy Clutch Disengagement Correction: If the clutch pedal pressure required to disengage clutch exceeds 28 lbs., check for dry release linkage and lubricate clutch pressure plate driving lugs as follows: Remove clutch housing lower cover, turn clutch so that driving lug is at bottom, brush small amount of 'Lubriplate' on each lug as pedal is being operated (lubricate all 3 lugs in same manner). If clutch still noisy, check clutch release bearing support for correct assembly, brush Lubriplate on bearing surface between release bearing retainer and support. Release lever pins that are dry and noisy can be corrected by spraying dry powdered graphite into pressure plate assembly (graphite will work into bearing when clutch is operated).

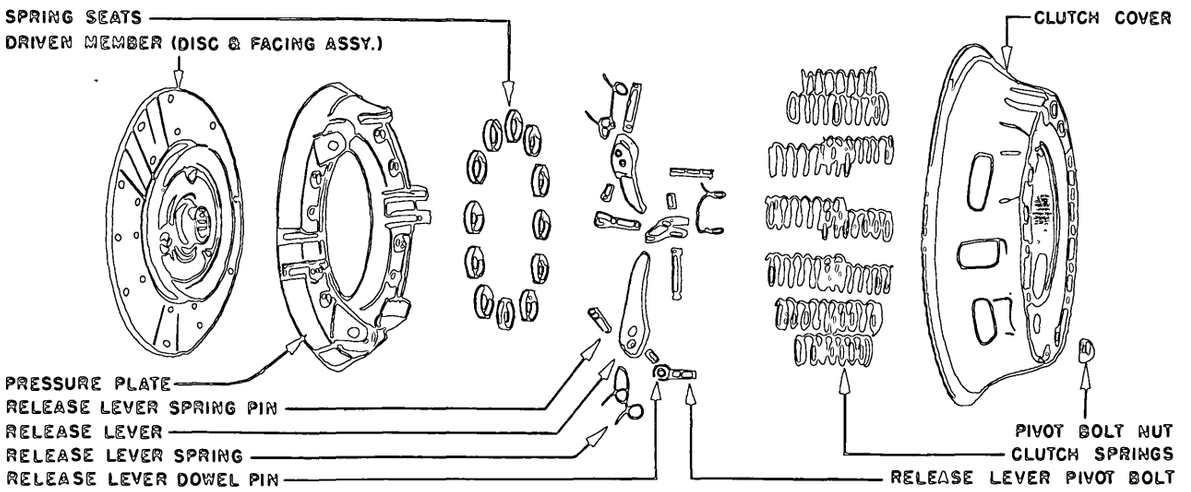
▷Clutch Rattle Correction: Rattles when the engine accelerated with clutch disengaged (similar to noise caused by loose connecting rods or pistons) may be caused by excessive clearance between pressure plate driving lugs and cover. To correct this condition, remove lower cover, turn clutch so that driving lug is down, hold clutch pedal in disengaged position, prick punch trailing edge of lug in 3 places so as to swell lug and take up clearance. Clearance between lug and cover should be .005-.008". Correct each lug in same manner.

DESCRIPTION: Single plate, dry disc type. Clutch mounted in slight recess in face of flywheel with pressure plate lugs in grooves cut in flywheel rim so that drive transmitted directly from flywheel to plate. Clutch is actuated by three release levers pivoted on adjusting bolts in cover plate and linked to pressure plate by pins in lugs on plate. Servicing directions below apply to pressure plate assembly and need not be followed unless pressure plate, springs, or release levers to be examined or replaced.

REMOVAL: *See "Clutch" on car model pages.*

OVERHAUL: Mark all parts before dismantling and reassemble in same position to maintain balance.

Disassembly: Place pressure plate assembly on arbor press, place block on cover (clearing release lever adjusting nuts) to take pressure, compress cover slightly, remove adjusting nuts, release pressure slowly. Lift off cover. This will expose all parts for inspection. Replace worn parts, check clutch springs.



Clutch Springs: Check spring pressure and replace if weak or burned. Twelve springs (3 groups of 4) used. Spring Pressure—135-145 lbs. at 1¾" spring length.

Assembling:—Place pressure plate on arbor press. Install pressure springs on plate. Place cover in position on springs, install guide pins on release lever adjusting bolts. Compress cover slightly guiding adjusting bolts through holes in cover, install adjusting nuts on bolts, remove assembly from arbor press.

Release Lever Height Adjustment:—Assemble gauge plate in flywheel in place of driven member, centering gauge in clutch with lugs on plate under release levers. Place short straightedge on top of gauge hub, or use dial indicator & service tool J-1013 mounting indicator on clutch so as to contact release lever tips. Turn adjusting nut until release lever just contacts straightedge or dial indicator and all levers are equal within .005", lock adjusting nut by crimping thin edge against flat on screws, using large pliers.

Gauge Plate—No. J-1036.

DRIVEN MEMBER: Spring dampener type hub used on all models. When replacing facings, drill out old rivets to avoid distorting clutch disc when removing old facings. Both Borglite type and new Long type Driven Members are used. Both types have woven facings which are grooved for quicker release. Driven members are balanced by use of extra rivets or clips on driven member hubs and these balance weights should not be removed. Driven members are serviced as an assembly (parts not furnished separately). CAUTION—Install driven member with large oil baffle toward transmission.

②—Rockford Clutch also used

AUBURN-ATWOOD NOTE: Clutches made by Auburn Company and formerly listed as "Atwood" now called "Auburn" clutches

►**RELEASE LEVER INTERFERENCE (causing premature clutch wear on first CJ-3A Jeeps):** On these cars and other models, check for interference between edges of clutch release lever and lever opening in bell housing which prevent full clutch engagement and cause premature wear of the clutch facings If interference noted, enlarge opening in bell housing by using a 1/8" or 3/16" drill to drill line of holes vertically 3" forward of rear edge of original opening and horizontally 3/16" above top edge, and 1/8" below lower edge of original opening, joining the vertical line of holes with the original opening Break out section of metal within this area with a wrench or drift

WILLYS DRIVEN MEMBER NOTE: Borg & Beck driven members used on all models *See Borg & Beck Type "A" Clutches*

DESCRIPTION: Clutch is single plate dry disc type Cover consists of a three-legged spider with channel section legs in which the clutch springs and release levers are mounted Release levers pivot on pins riveted in cover legs and actuate pressure plate through adjustable screws in pressure plate under outer end of each lever Springs are mounted in cups on cover under each lever Hairpin type retracting springs are mounted on each adjusting screw and are retained by the adjusting screw locknut

AUBURN CLUTCH

Willys Pressure Plate Assembly (8501-19 Clutch) Has neoprene rubber inserts at sides of pressure plate plate driving lugs (to prevent rattling or fizzing noise when disengaged) and flat Return Clip Spring on each release lever (to insure full disengagement)

REMOVAL OF CLUTCH: *See "Clutch" on car page*

SERVICING (Fixture C-585): Disassembly—Place cover support plate over main screw of fixture Install clutch cover assembly on Fixture C-585 Mark cover and pressure plate with punch and install compression washer and fully compress fingers Remove adjusting screw, washer and plate return spring or clip Place ½" steel block under outer end of each finger Back off compression nut slowly until release levers rise and contact steel blocks Remove nut and compression washer, lift off cover To remove release levers from cover, grind off one end of pin and drive out pin

Clutch Springs: Three springs used Spring pressure should be as follows

Dodge (9251-12)	251 lbs at 1 13/16"
Dodge & Plymouth (100052-2)	254-280 lbs at 1 1/16"
Frazer & Kaiser	251 lbs at 1 13/16"
Henry J (different type springs used)	
Blue Spring	230 lbs at 1 9/16"
Pink or Black Spring	211 lbs at 1 9/16"
Plymouth (9251)	222-246 lbs at 1 13/16"
Willys (Exc 8501-36, 39)	180-195 lbs at 1 9/16"
Willys (8501-36, 39)	180-203 lbs at 1 9/16"
Willys (6-226 4WD)	220-230 lbs at 1 9/16"
Willys (6-226 2WD)	239-264 lbs at 1 13/16"

Reassembly. Assemble levers to cover, peen over ends of lever pins Install pressure spring between lever and cover Make sure springs rest on bosses of cover and are seated in the embossed seats of levers Press down on release lever and then insert steel blocks under outer ends of levers Place pressure plate on fixture and place cover assembly over the pressure plate Match up punch marks so parts are in original positions Place spacer (see below) on center screw of fixture Install compression plate self-aligning washer, thrust washer and compression nut on center screw Tighten compression nut on fixture Install washers and adjusting screws in pressure plate Release fixture compression nut slowly and install pressure plate return springs

Release Lever Setting. Install the clutch cover plate assembly on fixture and make certain that housing clamps line up with holes With the spacer (see below), compression washer, self-aligning washer, and compression nut installed, tighten nut until release levers are completely compressed Install clutch housing clamps and tighten securely Adjust clutch release levers until each of the three feeler gauges has the same slight drag when being pushed in and out Tighten release lever screws to decrease drag or loosen them to increase drag Recheck adjustment of each lever tighten locknuts

Lever Setting (C-585 Fixture)

Car Model	C-585 Spacer
Dodge, Frazer, Kaiser, Plymouth	20
Henry J, Willys (Exc 6-226)	17
Willys (6-226)	20

Willys Return Clip Spring Installation—Engage slot on flat end of spring under head of release lever adjusting screw, engage loop on curved end of spring over ridge on outer end of release lever

►*INSTALLATION ON CLUTCHES IN SERVICE:* Clips can be installed by working through inspection hole in bell housing without dismantling clutch *CAUTION*—Use string attached to clip to prevent it dropping down into bell housing during installation

DRIVEN MEMBER: *See Car Model pages for Part Nos or facing specifications*

Utility , 6 Cyl (6-226) (1955) ②	10A7	982

②—Auburn Clutch also used
③—Chevrolet Part No
S-M—Synchro-mesh transmission

ASSEMBLY NUMBER NOTE: This number stamped on clutch cover Can be used to identify each model

►**Borg-Warner UF-300, 400 Fixtures:** Recommended by manufacturer for use in servicing clutch Fixtures consist of surface plate (duplicates the driving surface of flywheel) clamp screws to clamp clutch cover against plate, arbor press to compress springs in dismantling clutch, and gauge standard for use in setting up release levers

►**Borg & Beck Driven Members (with other Clutches):** Driven member data below applies to the following car models which use Borg & Beck Driven Member with clutches of other makes

Borg & Beck Driven Members

	Part No.
Buick 40 (1946-55)	CD890 or 381776
Buick 50 (1946-52)	CD890 or 381776
Buick 50, 60 (1953-55)	CD873 or 382213
Buick 70 (1946-48)	CD873 or CD724
Willys, 4 Cyl Utility (1946-54)	381580
Willys, 4 Cyl Utility (1955)	382298
Willys, 6 Cyl Sta Wgn (1954)	382231
Willys, 6 Cyl Others (Exc 6-226) (1948-55)	382213

►**Oldsmobile Throw-out Bearing Lubrication:** Bearing is special carbor (graphite) disc type and is impregnated with petrolatum On cars where clutch disengaged frequently, bearing should be lubricated at 5000 mile intervals using petrolatum or vaseline only in a small high pressure grease gun and filling through grease fitting on bearing until lubricant appears at vent hole at top *CAUTION*—Do not use any other lubricant than petrolatum or vaseline with high melting point (130°F)

DESCRIPTION: Single plate, dry disc Three release levers mounted on bolts piloted in pressure plate and held in clutch cover, actuate clutch through struts which provide 'knife-edge' action

Pressure Plate Baffle—Used on some Chrysler, DeSoto, Dodge, Plymouth, Nash, Oldsmobile Consists of a thin cupped steel disc assembled on pressure plate to prevent oil working in on facings When baffle plate used, release levers must be set higher

REMOVAL: *See "Clutch" on car model pages*

OVERHAUL. Mark all parts before dismantling clutch and reassemble in same position (necessary to maintain balance) Replace grooved, checked or warped pressure plates Replace springs when pressure plate discolored from heat (test springs as directed below)

DISASSEMBLY

Disassembly: Place clutch on fixture or arbor press (support pressure plate under release levers), place block across cover resting on spring bosses, compress cover slightly, remove metal staking in adjusting nuts by running hacksaw blade through slot remove nuts release pressure slowly remove cover and springs Remove release levers by grasping lever and eyebolt between thumb and forefinger so that inner end of lever and upper end of eyebolt are pressed together Lift strut over ridge in end of lever (press lower end back against lug), lift lever and eyebolt out

REASSEMBLY

Assembly: Place pressure plate on fixture or arbor press supporting plate under release lever lugs Install baffle plate (some models only—see Note below), install lever, eye bolt, and strut assemblies by reversing removal procedure Place pressure plate springs on the plate, and install the anti-rattler springs in the cover, place cover on pressure plate Make certain that springs are seated in cover recesses and anti-rattler springs in place on release levers Compress cover slowly and guide eyebolts through holes in cover If assembly made in fixture use clamps to clamp cover flange to plate at mounting holes Install eye bolt nuts and turn nuts down flush with head of bolt Compress and release clutch several times to seat all working parts Then adjust release lever heights

Clutch Grease Pad Installation (if used)—Three special grease-soaked pads installed on top of driving lugs on pressure plate When assembling clutch, make certain that holes in pads are over eye bolts If pads dry, dip them in good quality high-melting point grease which has been heated Allow pads to dry before installing Pads not furnished for service

Baffle Plate Installation Note (if used)—Place baffle plate on the clutch pressure plate with baffle plate ears on the special low spring seat ribs (adjacent to release lever lug on plate) in counter-clockwise direction so that flanged edge of baffle fits depressions in pressure plate at base of each lug and baffle is retained by springs (which seat on ears) when installed See that baffle plate ears are flat on spring seat ribs and that baffle seats fully in machined recess in plate (Straighten ears if bent by handling) *NOTE*—On 11A6 Clutch baffle ears must be seated on spring seats adjacent to lugs in **clockwise** direction

CONTINUED ON NEXT PAGE

BORG & BECK MODELS (Continu d)

Clutch Springs: Note spring color and install in same relative position (groups of two different springs used on some clutch models) Springs should check with table below Replace springs if weak or burned or if clutch has been subjected to excessive heat

RELEASE LEVER ADJUSTMENT

Release Lever Adjustment (On Borg-Warner Universal Fixtures UF-300, 400): Special lands must be installed on fixture under pressure plate lever lugs (all models with 3 levers—space lands equally on 4 lever types) Set adjusting arm on adjusting sleeve so that height of lower side arm above bottom of sleeve is correct for each model (see table below), install indicating plate on levers (see special note below on Models 9A7, 10A7 with new duckbill release levers) Adjust each lever so that it just contacts indicating plate or adjusting arm, lock lever adjusting nuts by peening nut against notches in eyebolt

B RG & BECK 8.5A6, 8A7, 9A7, 10A6, 10A7, 11A6 CLUTCH

MODEL 11A7	
3837155 (Chevrolet V8 Trucks)	

①—Used only with No 381558 Driven Member
②—1/16" higher with baffle

9A7, 10A7 Note—These models with 'duckbill' type release levers must be adjusted in special manner (longer length of levers makes it impossible to install height sleeve on fixture) With clutch mounted on fixture, place special extension sleeve '3Z' on spindle (this sleeve correct height for lever adjustment), place indicating plate on levers with counterbored side up Set adjusting arm flush with bottom of calibrated adjusting sleeve, install sleeve on spindle, adjust release levers in usual manner

RELEASE LEVER ADJUSTMENT (Using Gauge Plat)

Use gauge plate indicated in table below and install clutch on flywheel with gauge plate in place of regular driven member with lugs on gauge directly under release levers Use short straightedge placed on edge on gauge plate hub and adjust release levers so they just contact edge of straightedge for all models marked "flush" in table (If lever setting marked "high" a

CONTINUED ON NEXT PAGE

BORG & BECK MODELS (C n.inued)

cut-out or step must be made in edge of straightedge at one end so that levers can be set higher than hub, if lever setting marked "low" cut-out or step should be cut in gauge hub end of straightedge so that end extends below hub Cut-out or step should be in the amount "high" or "low" indicated in table) Lock adjustment by peening nut into notches in eyebolt

R l ase L ver Settings (Using Gauge Plate)

Car M d l	Gauge Plate	Lever Setting
Chevrolet V8 Truck	J-1048	1/8" High
Hudson Jet	J-5490	Flush
Hudson Wasp	J-5490	1/16" Low
Hudson Hornet	J-5490	1/32" High
Nash Ambassador	J-1507	Flush
Nash Statesman	J-5490	1/32" High
Metropolitan	J-5567	Flush
Rambler	J-5490	1/32" High
Oldsmobile	J-1048	Flush
Studebaker	J-4708	Flush

RELEASE LEVER ADJUSTMENT (C-585 & C-585A Fixture)

With C-585 & C-585A Clutch Fixture—On this fixture, feeler gauges are located in base of fixture under the clutch assembly Install the clutch assembly on fixture with release levers directly above feeler gauges (on 4-lever type 11" clutches, install clutch with two levers directly over two of the feeler gauges, adjust these levers, then rotate clutch so that other levers are over feelers and adjust these levers) Place correct spacers on center screw of fixture (see table below) install compression plate on center screw making certain that it rests directly against all release fingers (plate can be reversed to provide proper clearance on all models), install self-aligning washer, plain washer, and compression nut Tighten compression nut until clutch fully compressed, install clutch housing clamps over cover bolt holes and tighten clamps securely Adjust each release lever adjusting nut until slight drag secured on each feeler (all feelers alike), lock adjusting nuts and recheck adjustment

L ver Setting (C-585 & C-585A Fixture)

DRIVEN MEMBER

Driv n M mber Replac m nt Note: *Manufacturer recommends installation of new driven member with new facings rather than relining plate Driven member hub (Spring Dampener) cannot b serviced in the field*

"Spring-Flex" Borglite Driven Member: A composite plate consisting of a small diameter disc with separate clock-spring type cushion segments (to which facings are riveted) riveted to outer rim Segments are dishes to provide soft engagement This type of construction results in less weight at rim of driven member (which reduces spinning and allows quiet fast gear shifting) without loss of strength in plate Plate is balanced by additional rivets placed at rim of disc

Facings are riveted individually on segments by one or two rivets

To Remove Facings—Drill out rivets to remove old facings Do not punch out rivets as this will distort disc and damage tongues

Installing Facings—Insert rivets on facing side (head in countersunk hole of facing) Roll rivets on plate side—do not use split rivets Each facing must be riveted individually with facing drilled to permit working through facing to head rivets for facing in opposite side

(F D)—Fluid Drive
(T C.)—Torque Converter

①—Assy. No. stamped on cover for identification.

DESCRIPTION: Single plate dry disc type. Similar in design to Borg & Beck "A" type clutches except for the "Strap Drive" which consists of flat straps within the cover which are riveted at one end to the cover and bolted at the other end to the pressure plate. The straps deflect during pressure plate movement (for disengagement and engagement of the clutch) without rubbing contact and provide positive drive without friction or noise.

REMOVAL: *See "Clutch" on car model page.*

DISASSEMBLY & REASSEMBLY: Same as for Borg & Beck "A" clutches except that capscrews and washers in the drive straps which retain the pressure plate within the cover must also be removed to permit the cover to be lifted off (these screws accessible through holes in cover). Use the following specifications for these clutch models:

Clutch Spring Specifications

Clutch Assy.	Spring No. & Color	Pressure & Lgth.

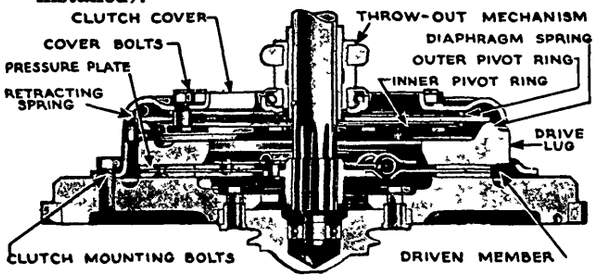
ℂ–This part number cast in plate
②–2402 cast in plate

►CHANGES, CAUTIONS, CORRECTIONS

►**Clutch Rattles at Idling Speed (Pedal Depressed & Clutch Disengaged) Correction:** May be due to insufficient tension of retracting springs and can be corrected without removing clutch from engine as follows: Remove clutch housing underpan, turn flywheel until one retracting spring is at bottom, remove bolt (work through hole in side of cover), withdraw spring, install new spring in same manner. Replace all three retracting springs in this way. If new springs do not correct rattles, check clearance between pressure plate lugs and edge of clutch cover slot. Clearance should be .002-.008" and clutch cover assembly or pressure plate should be replaced if clearance exceeds .010".

►**Clutch Balance Caution:** When installing pressure plate make certain that '0' marks on one lug of plate and on clutch cover flange are lined up. When installing clutch in engine, line up 'X' marks on clutch cover and flywheel. This is necessary to maintain clutch balance.



DESCRIPTION: Single plate dry disc type with diaphragm spring (replacing conventional clutch release spring and release levers. Diaphragm spring is shaped like dished washer with inner rim slotted to form 18 release fingers and is pivoted on inner and outer pivot rings mounted on 9 bolts in clutch cover.

REMOVAL: *See "Clutch' on car model pages.*

OVERHAUL: Manufacturer recommends the use of Clutch Pilot Tool K-411, to support clutch during disassembly, and Clutch Assembling Fixture J-1113, to compress diaphragm spring when disassembling and assembling pressure plate and cover assembly.

Retracting Spring Replacement. Does not require dismantling clutch. Remove clutch housing underpan, crank engine over until retracting spring bolt appears in lower opening, remove bolt, withdraw retracting spring, install new spring in same manner. Replace other retracting springs (3 used) in same manner.

Clutch Fork Removal. Can be removed without disturbing transmission. Remove flywheel underpan, disconnect clutch fork from pedal, use ⅞" and ¾" wrench to remove fork mounting, withdraw fork, remove ball retainer spring, ball retainer, ball. Pack ball seat in fork with high-melting point grease. NOTE—Install ball retainer spring with upturned ends down in ball retainer opening (will not seat in machined groove in fork if incorrectly installed).

Clutch Fork Installation—If retainer in groove in fork is worn, install new retainer being certain that high side of retainer is up (away from bottom of ball opening), and open end of retainer on the horizontal.

Clutch Fork & Bearing Installation. Pack ball seat in fork with small amount of high melting point grease. Install new retainer in clutch fork groove if old retainer worn, making certain that retainer installed with high side UP (away from bottom of bearing) and open end of retainer horizontal. Pack recess within throw-out bearing collar and coat throw-out fork groove lightly with high melting point grease before assembling to fork.

Disassembly: Take out screws and remove the three retracting springs through slots in cover (screws accessible through holes in side of cover), make certain that one pressure plate lug and cover marked to insure correct reassembly, remove pressure plate. On 1939 & later types, this completes disassembly operation (cover assembly, riveted and can not be dismantled.

Servicing: Wash all parts except the throw-out bearing in gasoline (see Caution below), examine pressure plate and flywheel face for scored or rough surface, check pressure plate drive lugs for burrs, see that lugs move freely in cover slots and that clearance in slots is .002-.008" (replace pressure plate or cover if clearance exceeds .010"). Check diaphragm spring and pivot rings for distortion or cracks. See that throw-out bearing is not rough and moves freely on clutch shaft sleeves, check transmission pilot hole in housing for run-out (must be less than .008"). Check clutch fork ball seat and ball fit, check driven disc and clutch shaft splines (replace disc if splines worn).

CAUTION—Throw-out bearing permanently lubricated and must not be soaked in gasoline which may dissolve lubricant on balls.

Reassembly: Reverse disassembly directions. Coat the special washers with graphite grease before installing. Make certain that lugs on pivot rings engage bolts (three pairs of lugs on each ring which must be placed at three of the bolts to prevent ring rotating). Install diaphragm spring with convex side up and compress spring so that it is flat while tightening bolt nuts on cover. Line up marks on pressure plate lug and cover when installing plate in cover assembly. See that cover plate nuts and retracting spring screws are tightened securely.

DRIVEN MEMBER: Two types used: 9" Type on Passenger Cars & Half-Ton, 10¾" Type on other trucks (this type Optl. on Pass. Cars & Half-Ton).

►***CAUTION—Two different clutch sizes used and parts (including driven member) not interchangeable.***

ℂ–Woven facing. ②–Molded facing.

Facing Installation—Drill old rivets out from head side. Use riveting fixture to install new facings (fixture will flatten rivets exact correct amount of 7/32"), and reverse rivets in pairs (two each way).

INSTALLATION: Remove and repack clutch bearing before installing clutch (see instructions below). Line up 'x' marks on flywheel and clutch cover, install cover bolts and tighten all bolts evenly, one turn at a time, to prevent distorting cover. Pack recess within clutch throw-out collar with high melting point lubricant and coat throw-out fork groove with lubricant before installing throw-out assembly. Make certain that throw-out fork ball is snug fit in fork without endplay (install new ball if scored or worn), pack seat with high melting point grease, make certain that upturned ends of ball seat retainer spring point down in ball retainer opening (retainer will not seat in groove in fork if spring installed incorrectly), install fork and tighten ball retainer securely.

Clutch Pilot Bearing—Clutch pilot bearing is an oil impregnated type bearing pressed into the crankshaft. This bearing requires attention only when the clutch is removed from the vehicle, at which time it should be cleaned and inspected for excessive wear or damage and should be replaced if necessary. To remove, install pilot bearing puller J-1448 and remove bearing from crankshaft. In replacing this bearing, use clutch pilot bearing driver J-1522. Place bearing on pilot of tool with radius in bore of bearing next to shoulder of tool and drive into crankshaft.

►**1946 & Later Pontiac Driven Member Note**—Driven members on 1946-49 Six & Eight are same size (9½") but must not be interchanged. Standard and Heavy Duty assemblies can be identified as follows:

Six Cyl. Types—Torsional springs in hub painted Dark Blue & Orange. Facings stenciled "Six 41-49" (Std.). "Six" without year mark (10" Heavy Duty).

Eight Cyl. Types—Torsional springs in hub painted Dark Blue & Brown. Facings stenciled "Eight 41-49" (Std.). "Eight" without year mark (10" Heavy Duty).

DESCRIPTION: Single plate, dry disc type. Release levers formed with weight on outer end which increase pressure on driven member as engine speed increases. Levers pivoted on pressure plate on needle bearings with fulcrum located in yoke support on cover plate. Hardened-steel screw contact provided on lever tips. These screws staked in place and should be disturbed only when release lever adjustment (for new or relined driven plate) is to be made. Servicing directions below apply to pressure plate assembly. See Driven Member Section below if pressure plate not to be dismantled and rebuilt.

REMOVAL: *See "Clutch" on car model page.*

OVERHAUL: Mark all parts before dismantling and reassemble in same position. Replace grooved, warped, or checked pressure plates. Replace springs if pressure plate discolored from heat.

Clutch Fixture Note:—Manufacturer recommends use of Borg-Warner Universal Clutch Fixture UF-300 or UF-400 for all servicing and rebuilding operations.

DISASSEMBLY

Disassembly: Place clutch on fixture (supporting pressure plate on special lands under lugs) or arbor press. Compress cover plate slightly, take out assembly screws (lever yoke mounting screws) on cover, release pressure on cover plate slowly, lift off plate. Note whether washers used on yokes under assembly screws (these washers must be reinstalled if old pressure plate used again). See special directions below on removing and reinstalling release levers. Remove and test clutch springs.

Pressure Plate:—Pressure plate refacing by grinding or turning down on lathe will throw release levers out of adjustment. If pressure plate being refinished, remove .020" from face and install spacer washer .015" thick on release lever yoke under cover.

NOTE—If washers are found on release lever yokes under cover when clutch disassembled, replace these washers (if old pressure plate used) or discard washers (if new pressure plate installed).

Clutch Springs:—Pressure springs should check with table below. Replace springs if weak or burned or if clutch has been subjected to excessive heat.

Clutch Spring Assemblies

208516	170-180 lbs.①	9	Pea Green
201983	154-164 lbs ④	9.65	Brown & White
209254	137-147 lbs ②	9 3	Bronze
211366	200-210 lbs ③	9	Aluminum

①—Pressure at height of 1 762".
②—Pressure at height of 1 747".
③—Pressure at height of 1 751"
④—Pressure at height of 1 736".

Release Lever Assembly:—Mount lever yoke on release lever, fasten by inserting flat-sided lever pin (flat side out or toward cover) and roller (place roller on flat side of pin). Insert lever in pressure plate lug, use roller pin sawed off to length of lever width as a guide and insert needle bearings, insert roller pin, pushing guide pin out, lock both lever pins with cotter pins. Thread release lever adjusting screws in ends of levers, turning screws down completely.

REASSEMBLY

Assembling:—Place pressure plate on fixture or arbor press. Assemble pressure springs, locator washers or insulator washers on plate, place washers on lever yokes (if washers used previously and old pressure plate being used). Place cover plate in position (lining up marks made before dismantling), compress cover slowly guiding lever weights through holes in cover and lining up yokes under cover plate holes. See that pressure springs are seated, insert cover screws in yokes, using lockwasher under screw head, tighten screws down securely. Compress and release clutch several times (using weight on release levers) to seat all parts. Then adjust release lever heights.

Release Lever Settings

9½ CF TYPES

①—Lever setting 2½" if dial indicator (and special gauge plate) used See data below

②—Lever setting 2 5/16" if dial indicator (and special gauge plate) used. See data below.

RELEASE LEVER ADJUSTMENT

Release Lever Adjustment (on Fixture):—Place special lands on fixture under pressure plate lugs, assemble lever adjusting arm and sleeve setting bottom of adjusting arm correct distance as showr in table above (all figures plus or minus 1/32") above bottom of sleeve and lock the adjusting arm with the thumbscrew. Swing arm over each release lever in turn, back off adjusting screw on tip of lever until rounded screw head just contacts arm, lock screws by inverting clutch so that screw head is supported and stake or peen lever into adjusting screw slot. Do not disturb lever yoke screws when making this adjustment.

Release Lever Adjustment (without Fixture):—Assemble the special lever setting disc or gauge on the flywheel in place of driven member, placing gauge so that lugs are under release levers and gauge is centered in clutch. Tighten all clutch cover bolts evenly. Place short straightedge on edge on top of gauge shoulder, turn adjusting screws at tips of release levers up or down until they contact straightedge, lock screws by peening metal of lever into screw slot. Lever heights must be equal within .005".

Release Lever Adjustment (Dial Indicator): When using dial indicator to set release levers, special indicating plate must be installed on levers and lever setting with this plate in place should be 2 5/16" on 9½CF No 268594 and 2½" on 9½CF No. L5385. Lever heights should be equal within .005". This indicating plate not used on other clutches.

DRIVEN MEMBER

NOTE: Clutch manufacturer recommends installation of new driven member with new clutch facings rather than relining clutch. Driven plate hub (Spring dampener) cannot be serviced in the field. Cushioning springs used under facing on pressure plate side of disc only.

To Remove Facings:—Drill out 12 iron rivets mounting cushion springs on plate (two rivets radially at center of each spring), remove spring and facing assembly, drill out rivets to remove springs from facing (replace springs as complete sets). Then drill out rivets mounting other facing on plate. Do not punch out rivets.

To Install Facings:—Install facings on flywheel side inserting brass rivets with heads in countersunk holes in facing and roll rivets on plate side (rivets staggered in inner and outer holes alternately around facing or placed two in a row radially). Place cushion springs on second facing with clearance at center between spring and facing, insert brass rivets with head in countersunk holes in facing and roll on spring side. Rivet layout same as for first facing except that rivets staggered in pposite direction or radial rows offset from rivets for first facing. Brass rivets must not project more than 1/32" when rolled (plate and spring cutaway to provide clearance). Place cushion spring and facing assembly on plate, insert iron rivets through holes in plate and spring, roll rivets (work through holes in facing). Driven member should be balanced after new facings installed.

Installing Driven Member:—Install with hub nuts on flywheel side and cushioned facing toward transmission.

INLAND

Pontiac 6 & 8 Cyl. Models (1946-55)

▷CHANGES, CAUTIONS, CORRECTIONS

▷1946-55 Models (except 1946-49 Taxi & Heavy Duty) Clutch Service—Pressure plate permanently assembled as part of cover assembly by four shallow 'U' shaped segments of flat spring steel riveted to pressure plate at center and to clutch cover flange at ends. These spring segments replace driving lugs and separate retracting springs.

▷Pontiac Clutch Poor Release Complaints—May be caused by the anti-rattle spring wearing into plate and binding at end of spring. To correct this condition, examine pressure plate and spring for indication of interference. Smooth up pressure plate to provide good bearing surface for face of spring. See that spring does not have end thrust on pressure plate lug (shorten end of spring if necessary). Lubricate spring with Lubriplate when reassembling. CAUTION—Driving lug slots must not be widened to correct poor release. Clearance in excess of .005" at either side of lug will cause clutch noise and roughness. When installing clutch, make certain that dowel in flywheel engages hole in cover (cover will be distorted and clutch out-of-balance if installed in any other position).

▷Pontiac Clutch Release Noises—If clucking noise noted when pedal depressed to release clutch, examine felts at each end of clutch control countershaft (clutch linkage cross-shaft) and lubricate if dry. IMPORTANT—These felts should be lubricated at regular lubrication periods

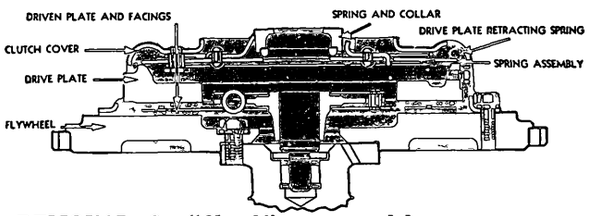
▷Pontiac Clutch Intermittent Buzzing Noise—Noise at about 28 MPH. which is not continuous may be caused by loose dampener spring in clutch driven member hub.

▷Pontiac 1946 Clutch Release Bearing Noise Correction—May be caused by excessive bearing clearance on first type support tube. See Clutch Notes in Pontiac Shop Notes in car model section for recommended correction.

▷Pontiac 1946 Release Bearing Support (New Type and recommended change on early 1946 cars). See Clutch Notes in Pontiac Shop Notes in car model section for complete data.

▷Pontiac 1946 & Later Driven Member Caution—Same size used for both 6 & 8 Cyl. cars (9½" Std., 10" Heavy Duty Taxicab & Sedan Delivery) but must not be interchanged and can be identified by hub spring color. *See Driven Member data.*

▷1950-55 Pontiac 8 Clutch: Larger 10" type (may be identified by greater diameter and six mounting bolt holes in cover *Can be used to replace 1946-49 Heavy Duty (10") clutch as an assembly (Cover & Pressure Plate Assy. and Driven Plate Assy.).*



DESCRIPTION: Single plate, dry disc, with diaphragm spring disc which takes the place of both pressure plate springs and release levers. Diaphragm spring is shaped like dished washer with inner rim slotted to form 18 segments or release fingers and is pivoted on inner and outer pivot rings assembled on inner surface of clutch cover by nine rivets. Diaphragm and pressure plate are linked by three tension or retracting springs mounted on edge of pressure plate by capscrews (springs and mounting screws visible through slots in cover). When diaphragm spring fingers depressed to release clutch, diaphragm pivots on inner pivot ring and resulting flexing action causes outer rim to move out relieving pressure on pressure plate and withdrawing plate from driven member. When diaphragm released to engage clutch, diaphragm flexs in opposite direction (pivoting on outer pivot ring) Pressure plate driving torque taken by three lugs on outer rim of plate which engage slots in cover

Pontiac Anti-Rattle Spring—Consists of a flat spring installed between the pressure plate and the clutch cover in one of the cover holes adjacent to the '0' balance marked lug hole. This anti-rattle spring should be wired in place before pressure plate is removed and must not be installed in any other position. CAUTION—Changing position of anti-rattle spring will upset clutch balance.

Clutch Applications

	Pontiac Cover Assy. Part No.
1946-49 Taxicab & Heavy Duty	①
1950-54 Sed Del, Taxi, Heavy Duty	758645
1946-54 6 Cyl (Std)	755959
1946-49 8 Cyl (Std)	755959
1950-54 8 Cyl (Std)	757370
1955 8 Cyl (Std)	758513

①—Clutch Cover No 753412, Pressure Plate No 753802

REMOVAL: *See "Clutch" on car model page.*

OVERHAUL: *CAUTION—Clutch (except on 1946-49 Taxicab & Heavy Duty) cannot be disassembled (riveted construction).* To disassemble clutch pressure plate and cover assembly on 1946-49 Taxicab & Heavy Duty models proceed as follows

▷Clutch Handling Caution—Pressure plate must not hang on retracting springs in clutch cover. When handling clutch cover assembly, support pressure plate by hand or invert assembly so that pressure plate is up.

Disassembly—Remove three screws holding three flat pressure plate retracting springs to pressure plate, remove pressure plate from clutch cover *CAUTION—Use care so as not to damage clutch pressure or driving plate retracting springs by dropping clutch assembly with pressure plate face down. Lay clutch assembly on bench with pressure plate face up.*

Inspection—Inspect clutch driven plate for broken or distorted torsion springs, worn or loose facings, oil on facings, and damaged spline which could cause binding If any of above defects noted, replace driven plate with new assembly Inspect pressure plate and cover assembly to see that it is free of oil and grease Check to see that diaphragm spring is not broken and fingers of spring are not distorted Examine release bearing support flange for distortion and that it seats fully into recess in clutch housing Examine support for burrs on outer surface which pilots clutch release bearing and on surface which contacts clutch housing counterbore at paper gasket surfaces If slight step found in clutch housing which prevents seating of bearing support flange chamfer, edge of support flange to allow it to seat, remove any burrs on edge of flange Check release bearing on bearing support for binding Check release bearing by placing thrust load on bearing by hand and turning bearing race. Replace if bearing feels rough when turning *CAUTION—Do not place bearing in degreasing solvent as this will wash lubricant out of bearing. Bearing is lubricated for life and sealed at factory.*

Assembly—Lay clutch cover and spring assembly with front side of cover up Apply light coating of high melting point grease to circular ridge on back of pressure plate against which outer edge of diaphragm spring seats and also to sides of three drive lugs on pressure plate Position pressure plate in clutch cover making sure "0" stamped on cover is in line with "0" stamped on one of drive lugs of pressure plate This is necessary to insure balance of complete assembly Install three flat pressure plate retracting springs See that shakeproof lockwasher is installed under each spring retaining bolt

DRIVEN MEMBER: Long "CF" type used on all models. *See "Long CF" Clutch data.*

	Pontiac Driven Member Part No. ①
1946-49 6 Cyl Sed Del, Taxi, Heavy Duty	502834
1950-54 6 Cyl Sed Del, Taxi, Heavy Duty	513582
1946-54 6 Cyl (Std.)	508403
1949 8 Cyl Sed. Del, Taxi, Heavy Duty	513583
1946-49 8 Cyl (Std)	505473
1950-54 8 Cyl. (Std)	513583
1955 8 Cyl (Std)	518130

Driven Member Servicing: Manufacturer recommends replacement of driven member when torsion springs distorted, facings worn or loose, oil present on facings, spline damaged

▷1946 & Later Pontiac Driven Member Note—Driven members on 1946-49 Six & Eight are same size (9½") but must not be interchanged. Standard and Heavy Duty assemblies can be identified as follows:

Six Cyl. Types—Torsional springs in hub painted Dark Blue & Orange. Facings stenciled "Six 41-49" (Std.), "Six" without year mark (10" Heavy Duty).

Eight Cyl. Types—Torsional springs in hub painted Dark Blue & Brown. Facings stenciled "Eight 41-49" (Std), "Eight" without year mark (10" Heavy Duty).

HUDSON (OWN)

All Models (1946-52)
All Models Except 1C, 2C, 1D, 2D, 3D (1953-54)

►***CLUTCH CAUTION:*** Two different sizes used (9" and 10") and correct driven member must be used with each size clutch. ***See Driven Member data.***

	Clutch Part Numbers		
Clutch Assy.	Cover	Press. Plate	Driven Member
303200 (9")	303201	166247	303342
301251 (10")	166338	303766	304885

DESCRIPTION: Single plate cork insert type operating in oil. Mounted on flywheel by 16 capscrews in cover flange. Gasket used under cover flange to secure oil-tight joint and oil seal mounted on throw-out collar to retain clutch lubricant. Clutch actuated by 3 clutch fingers pivoted on retainers bolted to cover and linked to pressure plate by pins.

REMOVAL: *See "Clutch" on car model page.*

OVERHAUL: Clutch cover need not be dismantled when replacing driven member unless springs are to be tested or replaced, pressure plate replaced, or other service work required. ***Check cover to determine whether disassembly required as follows:***

Checking Cover Assembly—Mount cover on flywheel or base plate with standard driven member (.200-.213" thick) and one gasket (.028-.032" uncompressed thickness) under flange (CAUTION—cover must be held by pressure on flange—not on cover flat or hub). Measure distance from contact surface of lowest clutch finger to top edge of cover hub. This distance should be 1¼-1½". If less than 1¼", clutch will perform satisfactorily if all fingers clear hub by at least ⅛". If distance greater than 1½", cover is distorted or fingers and retainers are worn. Dismantle for inspection as follows:

Dismantling:—Check punch marks near outer edge of pressure plate in line with mark on cover flange or make new marks to insure reassembly in same position. Place clutch assembly on special clutch fixture (#J-298-H) or in arbor press supporting pressure plate so that cover is free. Compress cover slightly, take off 3 nuts on clutch finger retainer bolts on cover, release pressure slowly, lift cover off.

Clutch Cover: Inner surface must be flat and free from scores at finger retainer holes. Front face must be flat within .005" when checked on a surface plate. Measure distance from face of cover flange (mounting face) to retainer washer seat on inner face of cover. This distance must be 2.350" minimum, 2.370" maximum, and equal within .008", measured ⅛" from edge of finger retainer holes. Straighten or replace cover if outside these limits.

►***CAUTION—If cover hub bore considerably worn or scored, check engine rear support plate, flywheel, and bell housing for misalignment or shaft eccentricity.***

Clutch Fingers & Retainers: Check fingers at contact points and pin bore for wear or uneven bearing surfaces. Check retainers for wear at finger contact point in slot. Replace retainers if bearing area grooved deeper than .005". NOTE—Retainers can be continued in service by rotating them 180° when installing so that unworn portion contacts finger lobe.

Pressure Plate:—Examine plate, replace if scored. Check for warping (particularly if plate 'blued' due to overheating). Replace if warped more than .010".

Clutch Springs:—Special combinations of large (outer) and small (inner) springs used on different models (inner springs not used on all models). Check springs and replace if pressure less than service limit in table below. Springs should be replaced if pressure plate 'blued' indicating overheating in service.

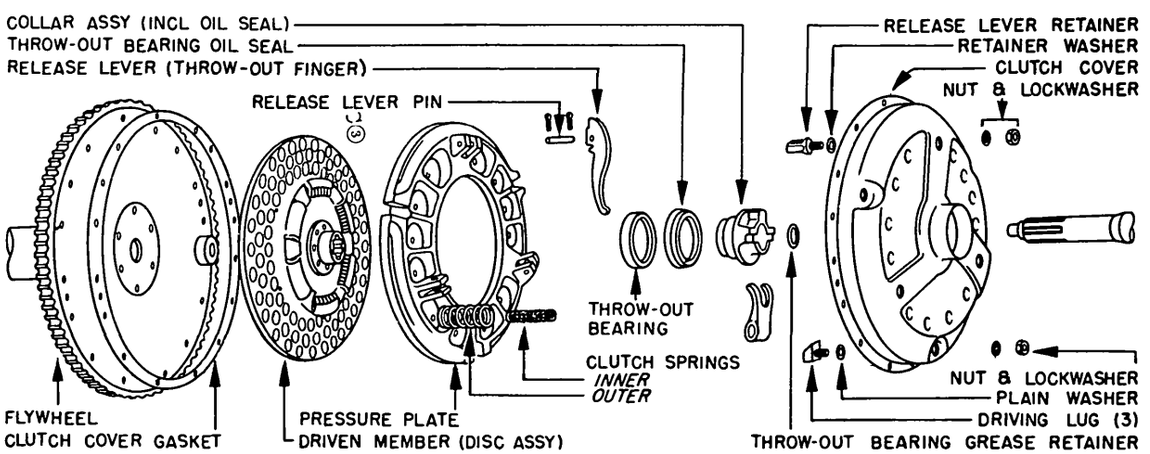
①—9" Clutch. ②—10" Clutch.
③—10" Clutch used on cars with Vacumotive Drive, Overdrive, Drive-Master, or Supermatic Drive.

Assembling:—Check clutch throw-out fingers, see that they are straight and do not show wear at tip or retainer lug. Replace retainer washers if necessary. Place pressure plate on fixture with face down. Assemble springs, clutch fingers, retainers and retainer washers on plate. Place cover on top of pressure plate assembly (lining up marks on cover and plate), compress cover slowly, guiding retainer bolts through holes in cover, install lockwashers and nuts on each finger retainer, tighten retainer nuts evenly to 40-45 ft. lbs. after cover has been fully compressed. Remove assembly from fixture and check alignment of clutch fingers in retainers, turn retainers with heavy duty end wrench until fingers centered sideways in retainer slots. See that shoulder on retainers fully seated on wall of cover. Check clutch finger heights with clutch installed on flywheel (below).



►***CAUTION—Retainer washers (copper or steel washer between retainer and cover) act as oil seals and must be flat and free from scores.***

INSTALLATION & ADJUSTMENT: Shellac new gasket on cover flange face, see that flywheel face is smooth and clean, use a clutch aligning arbor inserted through the clutch cover and driven plate to align driven plate, mount clutch assembly on flywheel (engaging two locating dowel pins on flywheel), install 16 cover screws, tighten screws evenly to 20-25 ft. lbs. (tighten screws diametrically opposite together to avoid distorting cover). Then align clutch fingers.

►***CAUTION—Use of more than one gasket (1/32" thick) between clutch cover and flywheel will reduce effective pressure of clutch springs equally.***

Clutch Finger Alignment: With clutch installed on flywheel, check distance from contact end of lowest clutch finger to top edge of cover hub. This distance should be within 1¼" to 1½". If less than 1¼", clutch will operate satisfactorily providing fingers clear cover hub by at least ⅛". If distance greater than 1½", check cover for distortion (see Clutch Cover). Adjust all clutch fingers as follows:

CONTINUED ON NEXT PAGE

HUDS N (OWN) CLUTCH

HUDSON (C nt.)

Clutch Finger Adjustment—Use special finger adjusting gauge (#J-774) resting gauge on clutch cover so that pin is directly above clutch finger tip. Turn thumbscrew down until pin contacts finger. Repeat at other clutch fingers to secure final gauge setting equal to lowest finger. If any finger more than .030" higher than others, adjust by installing thin (.005") washer between cover and retainer for this finger. If fingers more than .010" but less than .029" higher than others, turn gauge to higher finger, strike end of retainer bolt with soft hammer until gauge bar rests squarely on cover hub. With final setting, gauge bar should rest squarely on hub over all fingers and clearance between pin and end of thumbscrew must be less than .010" (all fingers equal within this amount—check with feeler gauge).

Throw- ut Bearing & Oil Seal:—Insert 1/3 pint Hudsonite through clutch hub before installing throwout collar assembly. Oil seal is pressed on collar behind throw-out bearing. When installing new oil seal, press firmly near inner diameter (pressure at point near rim may distort outer stamping and allow inner stamping and oil seal leather to revolve with shaft, this will cause noise similar to noisy throw-out bearing). Use arbor press to install throwout bearing (do not drive on). See that bearing revolves smoothly and that oil seal inner stamping is tight in outer stamping before installing collar in clutch cover.

CAUTION—Install new grease retainer in annular recess in throw-out bearing when assembling bearing on collar. Soak this retainer and oil seal in engine oil for at least 30 minutes before installing.

DRIVEN PLATE: Plate has a spring-dampener **type hub and facing consisting of cork inserts. Examine driven member, see that plate runs true and do not have appreciable free play. See that hub is not warped or distorted, and that springs in hub splines are not worn and are free from burrs. Corks must be in good condition. Black glaze indicates use of wrong lubricant. Soak driven plate in Hudsonite and clean corks, or replace driven member.**

1946-47 Driven Member Specifications

Car Model	Outside Diameter	No. of Corks
6 Cyl. Pass. Cars Std.	9"	90
6 Cyl. Pass. Cars Overdrive	10"	108

ROCKFORD 8½RM

MODEL 8½RM

HENRY J	Rockford No.
All Models (1951-54)①	165264
WILLYS	
All Models Exc 6-226 Eng (1946-55)	②165317

①—Auburn Clutch also used

②—Can also use Clutch Assembly R3030 or 165264 from 1946 through 1952.

DESCRIPTION: Single plate, dry disc type. Clutch is three-lever type with six springs mounted in pairs adjacent to levers.

REMOVAL: *See "Clutch" on car model pages.*

OVERHAUL: Clutch cover and pressure plate assembly need not be disassembled when replacing driven member unless springs are to be replaced or other service work performed.

Disassembly: Place cover assembly in arbor press, compress cover slightly, remove release lever pivot pins, unhook lever springs, remove levers. Release pressure slowly, lift off cover.

Clutch Springs: Check springs and replace if weak or burnt. Springs should check as follows:

Spring Specifications

Cover Assy.	Spring Part No.	Pressure & Length
R3030	M-2317-4	140-150 lbs at 1 7/16"
165264	M-2317-9	170-180 lbs at 1 7/16"
165317	105348	

Reassembly: Reverse disassembly procedure, make certain that pressure plate springs seated in pressure plate and cover and that lever springs correctly installed. Check lever heights after assembly completed.

Release Lever Setting: Manufacturer recommends use of Borg-Warner Fixture UF-300 or 400 for lever adjustment. Lever setting should be as follows·

Release Lever Setting

Clutch Assy.	Release Lever Height
R3030	2 13/32"
165264	①1 25/32"
165317	②2 5/16"

①—Dial indicator only

②—Use only 3 clamps on UF-300 Fixture

DRIVEN MEMBER: Borg & Beck "Borglite" type with spring dampener hub. *See car model page for facing specifications.*

Borg & Beck Driven Member

Car Model	Borg & Beck Part No.
Henry J 4 Cyl	382000
Henry J 6 Cyl	381947
Willys 4 Cyl	381580
Willys 6 Cyl	382113

ROCKFORD 6TS & 6½TS

Assy. No. MODEL 6TS

R-4608—Crosley, All Models (1939 to 1950)

MODEL 6½TS

165299—Crosley, All (Late 1950, 1951-52)

►**6TS & 6½TS Production Change Note**—Model 6½TS is larger clutch and was used on 1950 cars beginning with Serial No. CD-205500 & VC-20783.

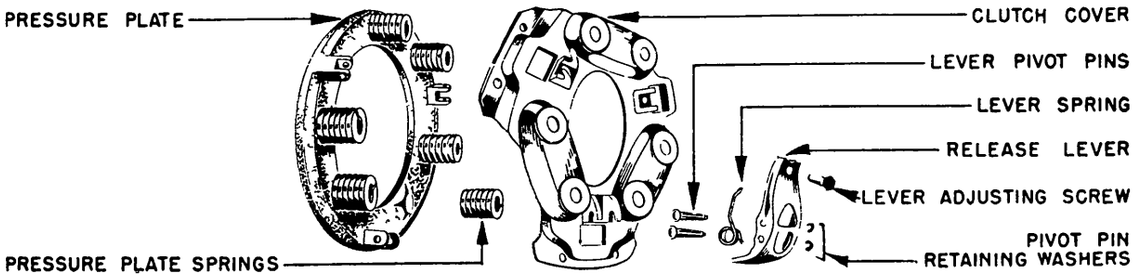
DESCRIPTION: Single plate, dry disc type. Clutch assembly consists of 3 fulcrum brackets (mounting brackets) which are bolted individually on the flywheel. Release levers are pivoted on pins in fulcrum brackets and engage lugs on pressure plate with pressure spring mounted on pressure plate under each lever (3 springs used).

REMOVAL: *See "Clutch" on car model pages.*

OVERHAUL: Disassembly. Take out cotter pin and remove pin linking release lever to fulcrum bracket, remove release lever and spring. Repeat this operation at each of the three fulcrum brackets.

Assembly—Install fulcrum bracket on pressure plate lug, install spring, place release lever in position with hole in lever and fulcrum bracket lined up, install pin and secure with cotter pin.

Spring Pressures



Clutch Type	Pressure & Length
6TS	52½ lbs at 13/16"
6½TS	67½ lbs at 1⅛"

Release Lever Setting: (6TS) None required. (6½TS) 9/32" or 1 23/32" from surface plate

DRIVEN MEMBER: Consists of steel disc with slotted rim on which linings are riveted in four separate segments. Each lining segment retained by three rivets with rivet heads reversed on alternate segments (rivet heads toward flywheel on adjacent segments).

Servicing—Facings not furnished separately and driven member should be serviced by replacem nt.

CLUTCH THROWOUT BEARING: Throwout bearing is sealed with lubricant during assembly and need not be refilled Should clutch fail to disengage when clutch pedal is pushed down to floor, clevis which attaches to bottom of yoke can be adjusted to correct this difficulty

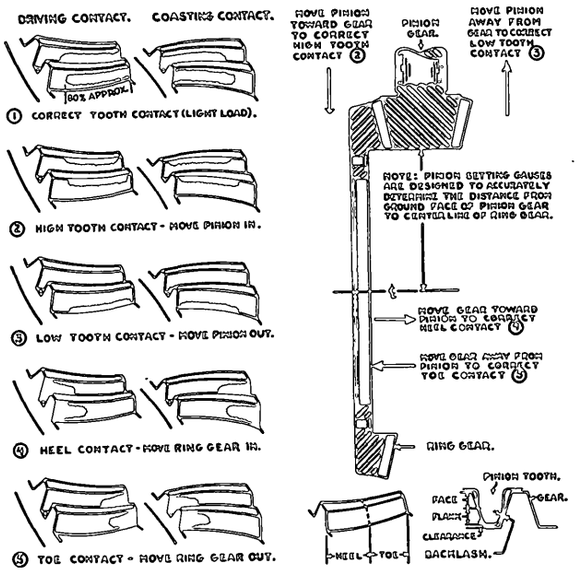
SPIRAL BEVEL & HYPOID GEAR ADJUSTMENT (ALL MAKES)



NOTE ON PINION SETTING GAUGES: These gauges are designed to locate the pinion gear (with respect to ring gear center line) so as to duplicate the factory set up when the gears were burnished or run in. Mated gears of this type will run quieter and give more satisfactory service in this position and other settings should not be used. See separate articles for each type axle and complete instructions and specifications for use of these gauges.

RING AND PINION GEAR MESH: To check gears, paint a number of ring gear teeth with some suitable indicator such as Prussian Blue or red lead mixed with oil. Rotate ring gear by hand applying tension on pinion shaft flange with a block of wood to simulate load. Indicator will be wiped off on teeth in area of tooth contact so that mesh can be judged. See illustration (No. 1) for desired tooth contact and possible variations which should be corrected as directed below. If desired, gears can be turned over a few times by the engine with the rear wheels jacked up and brakes applied for load (preliminary inspection of mesh should be made by turning gears by hand to avoid damage caused by running gears under load when badly meshed).

High Tooth Contact (Illustration No. 2):—Will be noisy and cause gear teeth to roll over at top if run for any length of time. To correct, move pinion in toward ring gear. If backlash is then insufficient, move ring gear away from pinion.

Low Tooth Contact (Illustration No. 3):—Will be noisy and gear teeth will groove or score if run with this setting. To correct, move pinion out or away from ring gear. If backlash is then excessive, move ring gear in toward pinion to decrease backlash.

Heel Contact (Illustration No. 4):—Will be noisy and cause excessive wear, chipping, and tooth breakage. To correct, move ring gear in toward pinion. If backlash is then insufficient, move pinion out or away from ring gear to increase backlash.

Toe Contact (Illustration No. 5):—Will be noisy and cause excessive wear due to small contact area, chipping, and tooth breakage. To correct, move ring gear away from pinion. If backlash then excessive, move pinion in toward ring gear.

Backlash Specifications:—See individual Rear Axle articles for recommended backlash for each axle type and complete directions on moving pinion and ring gears to secure above adjustments.

TROUBLE SHOOTING: Before attempting to classify rear axle trouble from noise (hum or growl), eliminate other sources such as tires, engine, transmission as follows:

Tire Noise. Will change on different road surfaces and continue as speed decreases, will be more noticeable with low pressures. To check, coast car with gears in neutral from speed of 30 M.P.H. down. Rear axle noise will ordinarily disappear, tire noise will continue with lower tone as speed decreases.

Engine & Transmission. With car stationary, hold clutch disengaged, operate engine and vary speed through range in which noise previously noticed, check for similar sound. Then repeat test, engaging clutch to note transmission idling noises (gears in neutral). This will also check for muffler and exhaust noise.

REAR AXLE TROUBLE SHOOTING TABLE

REAR AXLE NOISY

1. Drive Noise. Most pronounced when car accelerated at constant rate from 15 to 45 M.P.H. Pinion should be moved in toward ring gear slightly.
2. Coasting Noise. Most evident when car allowed to coast from 45 M.P.H. down to 15 M.P.H. with throttle closed and clutch engaged. Pinion should be moved out or away from ring gear slightly.
3. Float Noise. Most evident when speed held constant at close intervals between 15 and 45 M.P.H. Correct by same adjustment as for coasting noise above, or by changing backlash slightly.
4. Continuous Noise. Check axle shaft bearing, differential bearing, pinion bearing adjustment. Check ring and pinion gear for incorrect adjustment, not matched or defective, gear teeth badly worn, scuffed or chipped. Backlash may be excessive or insufficient.
5. Noisy on Turns. Check for tight, binding, chipped, scuffed differential pinion gears or side gears, worn or rough thrust washers, excessive differential gear backlash, excessive axle shaft endplay.
6. Intermittent Noise. Check for sprung or warped differential case, excessive ring gear runout, loose or broken differential bearings.

REAR WHEELS DO NOT TURN

If rear wheels do not turn with engine running, transmission in gear, and propeller shaft rotating, check the following points:

1. Axle Shaft—Shaft broken or key sheared.
2. Ring & Pinion Gear—Teeth stripped, pinion gear shaft key (Hotchkiss Drive), pin (torque tube drive) sheared.
3. Differential—Side gear or pinion teeth stripped, differential pinion shaft or spider broken.

SPICER SPIRAL BEVEL

Car Model	Spicer Model
Crosley, All Models (1941-52)	11

▷CROSLEY NOTE: Crosley axle is new design with Torque Tube Drive. Serviced in same manner as other Spicer models after Torque Tube has been removed. 1946-47 Torque Tube modified type for new universal joint mounting (in adapter at rear end of transmission case). *Refer to Crosley Shop Notes in Car Model Section for torque tube data.*

DESCRIPTION: Spiral bevel, semi-floating type with Hotchkiss Drive.

REMOVAL OF AXLE: *See "Rear Axle" on car model page.*

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: When replacing an axle shaft, check endplay. Total endplay between shafts and spacer in differential which transmits thrust from one shaft to the other should be .002-.007" except as noted in the table below. Adjust endplay by removing shims between backing plate and axle housing flange (at one wheel if clearance less than maximum, both wheels if greater). Shims furnished .003", .005", .010", .030" thick.

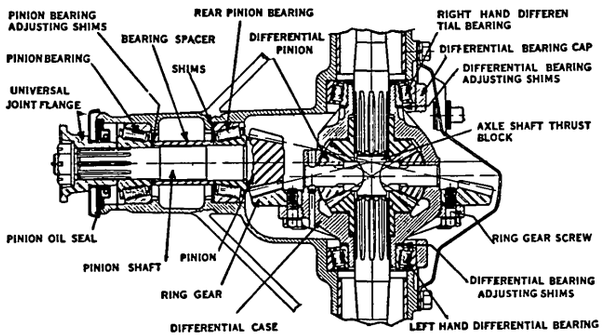
Car Model	Axle Shaft Endplay
Crosley	.002-.007"
All Other Cars	.002-.007"

OVERHAUL: Disassembly—To remove differential assembly (with axle shafts out), take out bearing cap screws, make certain that bearing caps marked to insure correct reassembly, remove bearing caps, pry differential assembly out of housing. Remove nut on end of pinion shaft, pull rear universal joint companion flange, press or drive pinion out at rear of housing (use brass drift on end of shaft), note number and thickness of shims between spacer on shaft and front bearing cone (these shims control bearing adjustment). Use puller to remove pinion rear bearing cup from housing, note number and thickness of shims located in bearing cup recess in housing (these shims control pinion setting). Remove oil seal from front of housing, drive pinion front bearing cup out. Disassemble and service sub-assemblies as follows:

Pinion Bearing Assembly & Adjustment: When dismantling pinion assembly, pinion should be pressed out (to avoid damaging forward bearing) and oil seal should be pried out. Use new oil seal when reassembling if old seal damaged by removal. To adjust bearings, add or remove shims between forward bearing cone and spacer (or shoulder on pinion shaft on types where no spacer used), install universal joint flange and tighten nut securely. Pinion should rotate with slight drag (approximately .002" tight). Shims furnished .003", .005", .010", .030" thick.

Pinion Setting:—Use special pinion setting gauge, Salisbury No. J-772 or Studebaker No. HMJ-589, set gauge for correct zero position for each axle type or car model as shown in table below (correct for pinions marked 'O'). Figure etched on end of each pinion indicates amount in thousandths which pinion should be set ahead (plus figures) or in back (minus figures) of this zero position. Install gauge in axle housing in place of differential assembly, adjust pinion position by adding or removing shims

CONTINUED ON NEXT PAGE



SPICER SPIRAL BEVEL (Cont.)

between rear pinion bearing cup and shoulder in housing until correct gauge reading is secured (see note below for hypoid axles). Recheck pinion bearing adjustment (disturbed by pinion setting adjustment). Shims furnished .003", .005", .010" thick.

Axle Type.	Pinion Zero Setting.
11	See Model 11 Note

Model 11 Note—This is special small axle and the regular pinion setting gauge cannot be used. Car manufacturer recommends that gear mesh be checked by painting the gears and turning them by hand.

Differential Bearing Adjustment:—Shims installed between bearing cones and differential case on each side. To adjust bearings, take out axle shafts, take off rear cover, remove capscrews and lift off differential bearing caps, then pull out differential assembly. Remove bearing cones, add or remove shims installed between bearing cone and case on each side until assembly will just slide into place in axle housing, then add additional shim thickness of .003-.006" (.008-.010" on Studebaker models), install

assembly, tighten bearing caps. Ring gear should have fairly heavy drag when revolved by hand. Shims furnished .003", .005", .010", .030" thick.
NOTE—Early models fitted with adjusting nut at each bearing. These types adjusted by removing locks, loosening bearing caps, and turning up adjusting nuts to secure desired bearing adjustment.

Ring & Pinion Gear Adjustment: Paint gears to check mesh or check pinion setting (see directions below). Backlash should be .004-.008" on all cars except as noted in table below. Adjust backlash by shifting differential bearing adjusting shims from one side to the other (total shim thickness must not be changed to avoid disturbing differential bearing adjustment). See Pinion Setting and Differential Bearing Adjustment below.

Ring-and-Pinion Gear Backlash

Car Model	Backlash
Crosley	.003-.008"

Ring Gear Backlash:—Adjusted by transfering shims from behind left hand bearing to right hand bearing (to increase backlash), or from right to left (to decrease backlash). Total shim thickness must not be changed to maintain bearing adjustment. Moving ring gear .005" changes backlash .0035".

SPICER FULL-FLOATING FRONT & REAR AXLE

REAR AXLE

Car Model	Spicer Model
Willys Jeep, Model CJ-2A (Early 1946)	23-2

FRONT AXLE

Car Model	Spicer Model
Willys Jeep CJ-2A (1946-48)	25
Willys Jeep CJ-3A (1948-53)	25
Willys, 4x4 Station Wagon (1949-50)	25
Willys, 4x4 Truck (1947-50)	25

►CHANGES, CAUTIONS, CORRECTIONS

►*1946 WILLYS JEEP NOTE:* Full-floating type rear axle used only on first 1946 Jeeps. Later models have semi-floating type. See "Spicer Hypoid Semi-Floating" type following.

►*4WD FRONT AXLE PRODUCTION CHANGE:* Effective Serial No. 37549 (CJ-3A) and No. 14284 (4x4 Truck & Station Wagon) front axle shaft outer splined end floats in wheel driving flange and is not retained by nut and lockwasher. It is no longer necessary to install shims between driving flange and wheel hub to provide correct end float of axle shaft universal joint.

►*1953 FRONT AXLE (RZEPPA TYPE UNIVERSALS) NOTE:* The inner shaft retainer and three screws have been eliminated making it possible to pull shaft end from joint without dismantling joint.

DESCRIPTION: Hypoid Gear, full-floating type, with Hotchkiss Drive. These axles similar to Spicer semi-floating type except for axle shaft and wheel bearings (wheel bearings on rear axle are double opposed taper roller bearing type which take thrust in both directions) so that no thrust block used at inner end of axle shafts.

REAR AXLE (MODEL 23-2) NOTE: Differential assembly is same as that used in Model 25 Front Axle and all data below on Disassembly, Pinion Bearing Assembly and Pinion Setting, Differential Bearing Adjustment, and Ring Gear Backlash, apply to this model also. *See Willys Jeep car page for data on wheel bearing adjustment.*

REMOVAL OF AXLE: *See Car Model Pages.*

AXLE SHAFT REMOVAL & WHEEL BEARING & END-PLAY ADJUSTMENT: *See Car Model Pages.*

OVERHAUL & ADJUSTMENT: *Follow procedur s outlined under "Spicer Hypoid Semi-Floating-Models 23, 23-1, 23-6, 41-2, 41-6, 41-7" and note the following:*

Pinion Setting With Special Pini n Setting Gauge W-99: Use Master Gauge Blocks as follows:

Car Model	Master Gaug Bl ck
CJ-2A (Front Axles)	D
CJ-2A (Rear Axles to Serial No. 13454)	D
CJ-3A (To Serial No. 62488)	B

►CHANGES & CORRECTIONS

►*1953 TYPE 23-1 PINION SHAFT PRODUCTION CHANGE:* Late type pinion shaft has square shoulder added at inner end of spline shaft (early type has very noticeable radius at this point) eliminating need for pinion bearing spacer. Early and late type pinions have same part number and are interchangeable. When installing early type drive pinion with radius, pinion bearing spacer must be used.

CAUTION—Location of pinion bearing adjustment shims are different on the two types of pinion shafts. *See "Pinion Bearing Adjustment" below.*

►**Willys Jeep CJ-2A 1946 Production Change.** Full-floating Spicer Model 23-2 Rear Axle used on cars before Serial No. 13453. *See Spicer Full-floating Rear Axle.*

DESCRIPTION: Hypoid gear, semi-floating type with Hotchkiss Drive. Hypoid gear pinion is integral with the pinion shaft and is mounted on taper roller bearings which seat directly against shoulders in housing.

AXLE SHAFT REMOVAL & WHEEL BEARING & ENDPLAY ADJUSTMENT: *See Car Model Page.*

REMOVAL OF AXLE: *See "Rear Axle" on car model page.*

OVERHAUL: Disassembly. To remove differential assembly (with axle shafts out), take out bearing cap screws, make certain that bearing caps marked to insure correct reassembly, install spreader tool on axle housing (Kaiser-Frazer & Willys No. W-129) to facilitate differential assembly removal, or pry assembly out using a pry bar on each side of differential case. Remove nut on end of pinion shaft, pull rear universal joint companion flange, press or drive pinion out at rear of housing (use brass drift on end of shaft), note number and thickness of shims between spacer on shaft and front bearing cone (spacer not used on late 1953 and later axles). Spacer eliminated, and shims located between front

CONTINUED ON NEXT PAGE

SPICER HYPOID (C nt.) (MODELS 23, 41)

bearing cone and shoulder on pinion shaft), these shims control pinion bearing adjustment Use puller to remove rear bearing cup from housing, **note number and thickness of shims** located in bearing cup recess in housing, these shims control pinion gear setting Remove oil seal from front of housing, drive front pinion bearing cup out

Pinion Bearing Assembly:—Make certain that pinion setting shims installed in housing ahead of rear bearing cup, insert pinion and rear bearing cone in housing from rear, install spacer (except Late 1953 and later axles), and pinion bearing adjusting shims on pinion shaft, tap front bearing cone on pinion shaft, assemble universal joint flange, tighten nut securely (if bearing adjustment to be checked, oil seal assembly may be left out until adjustment is completed)

Pinion Bearing Adjustment. With pinion shaft nut tight, pinion should rotate with slight drag (no endplay). Adjust by removing front bearing cone and adding or removing shims between cone and spacer r shoulder on shaft. Shims furnished .003," .005", .010", .030" thick.

►**Frazer & Kaiser Note—Above setting will be secured with .003" tight fit of pinion bearings (.003" additional thickness of shims after all endplay removed from pinion bearings).**

Pinion Setting With Special Pinion Setting Gauge Salisbury No. J-722 (Studebaker Tool No. J-589-D): Set micrometer gauge to correct figure for each axle model (see table below—this figure correct for standard pinions marked 'O' on end) and correct micrometer for each pinion as follows: Figures etched on pinion indicates amount (in thousandths) that pinion should be set in toward ring gear (— figures) or out away from gear (+ figures). Install gauge in axle housing in place of differential assembly with side discs seated in differential bearing bores (different size discs used for Champion and Commander), add or remove shims located between rear bearing cup and shoulder in housing until micrometer pointer just contacts ground face of adapter. Pinion setting shims are .003", .005", .010" thick.

Studebaker Model	Pinion Zero Setting
1946-54 Champion	719"
1955 Champion (Exc 3 54 ratio)	719"
1955 Champion (3 54 ratio)	625"
1946-50 Commander	719"
1955 Commander (Exc 3 54-1 ratio)	719"
1955 Commander (3 54 ratio)	625"

►**Pinion Setting Note—The above "Pinion Zero Setting' figure should be corrected by adding (when Pinions marked —), or subtracting (when pinions marked +), shim thickness equal in thousandths of inch to the figure stamped on the pinion immediately following + or — mark.**

Pinion Setting With Special Pinion Setting Gauge W-99): This gauge consists of a dial indicator and mounting fixture designed to be mounted on rear face of pinion (held in place by "C" clamp which is part of gauge). Before using this gauge, dial indicator must be set at zero through use of a "master gauge" supplied with this equipment. Set the dial indicator at zero with gauge pin resting on correct lobe of master gauge and with one-half turn tension on the gauge pin (master gauge table below). With pinion installed in axle housing (spacer tool W-126-6 can be installed on shaft in place of universal joint yoke), and with pinion setting gauge in place, dial reading should be ZERO for pinions marked "O", and should read PLUS (for pinions marked +) or MINUS (for pinions marked —) by an amount equal to the figure following this + or — sign on the pinion. Adjust by adding or removing shims from behind rear bearing cup in housing and repeat test until correct dial reading is secured.

Pinion Gauge Zero Setting

Willys CJ-2A Jeep (To No 13454)	D
Willys CJ-2A Jeep (From No 13454)	B
Willys CJ-3A Jeep (To No 62488)	B
Willys, Others	B

Differential Bearing Adjustment:—Shims installed on differential case hub at inner end of each bearing cone. To adjust differential bearings (with axle dismantled), remove bearing cones, add or remove shims until differential assembly will just slide into housing (no endplay when installed). then add additional 008" of shims for correct pre-load Shims furnished .003", .005", .010", .030" thick. With correct adjustment, fairly heavy drag should be felt when ring gear revolved by hand (test preferably with pinion out to avoid added drag of pinion bearings and oil seal). When installing differential assembly, tighten bearing cap screws securely.

Ring & Pinion Gear Adjustment: Paint gears to check mesh, or check pinion setting Back lash should be as indicated in table below Adjust by shifting differential bearing adjusting shims from one side of differential case to the other See Differential Bearing Adjustment above *(CAUTION*—Total number of shims must not be changed in making this adjustment—would affect differential bearing adjustment) Shifting ring gear 005' will change backlash approximately 0035"

①—This axle used optionally with "Timken Semi-Floating" Rear Axle since August, 1951.

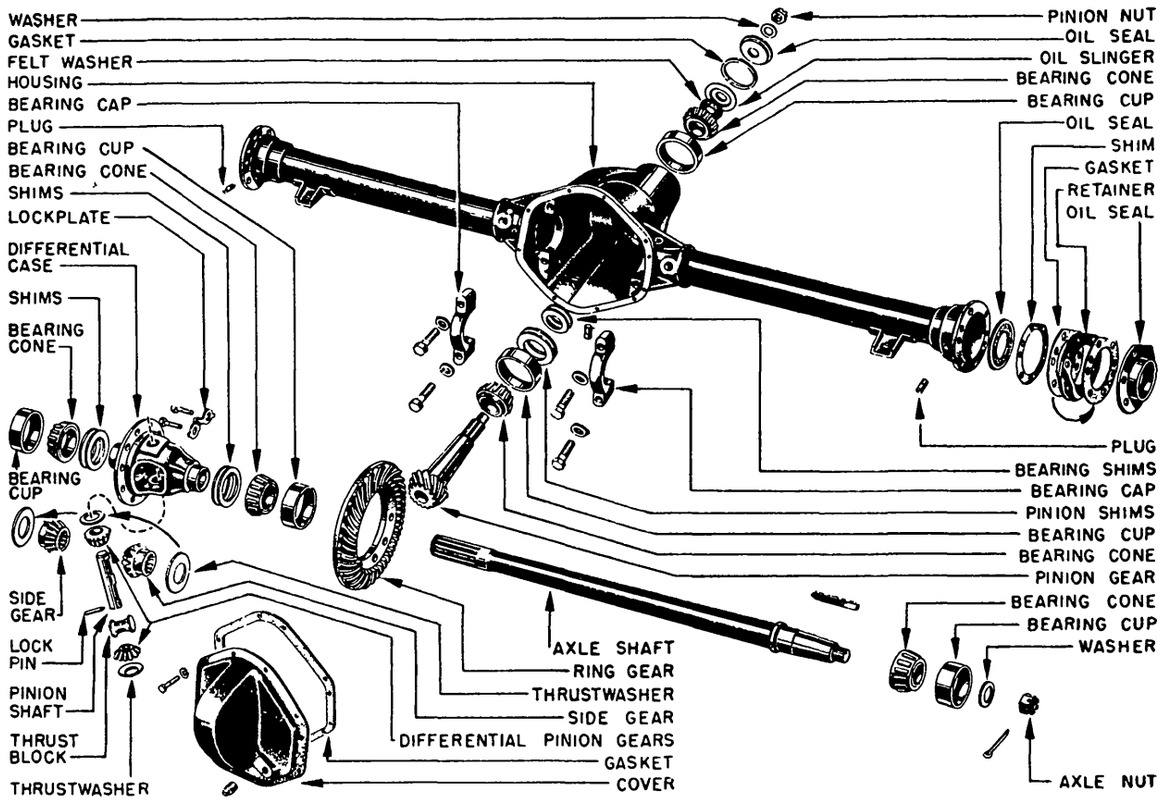
①—Late 1952 Cars with "Dual-Range" Hydra-Matic Transmission

►*NOTE—See Separate article for Model 23 & 41 Spicer Rear Axles.*

►CHANGES, CAUTIONS, CORRECTIONS

►***LINCOLN, MERCURY, FORD STATION WAGON, FORD SEDAN DELIVERY & F-1 TRUCK—See Ford, Lincoln, Mercury Rear Axle.***

►***WILLYS 4WD FRONT AXLE OVERHAUL NOTE***—Overhaul procedures outlined below for Rear Axles apply equally to Willys 4WD Front Axles.



►***WILLYS FRONT AXLE (RZEPPA TYPE) NOTE***—The inner shaft retainer and three screws have been eliminated, making it possible to pull the shaft end from the joint without dismantling joint.

►***AXLE RATIO CHANGE CAUTION—Use correct differential case if gear and pinion ratios changed.***

DESCRIPTION: Hypoid gear, semi-floating type with Hotchkiss Drive of same design used beginning 1946.

►***REAR AXLE NOTE:*** These axles differ from previous axles in the size of the ring gear and pinion, shape of axle housing, and the elimination of the pinion bearing spacer. Axle housing cover is flat on two sides and rounded on other two, or hexagonal in shape

AXLE SHAFT REMOVAL & WHEEL BEARING ADJUSTMENT: Bearing adjustment (endplay) can be made without removing axle shafts (see below). **Axle Shaft Removal**—Remove wheel, take off axle shaft nut and washer, use puller to remove hub and brake drum assembly. Disconnect brake line and cables take out bolts mounting oil seal assembly and backing plate on axle housing flange and remove backing plate (do not lose wheel bearing shims), pull axle shaft and bearing assembly out Use bearing puller and remove bearing from shaft. **Axle Shaft Endplay**—Total endplay for both shafts should be as noted below. Endplay controlled by shims placed between axle housing flange and brake backing plate (right side only). Left side of axle housing has a permanent shim pack of .060", or housing has been machined .060" longer for inside centering of axle shaft in spacer block. (NOTE—

SPICER SEMI-FLOATING HYPOID AXLE

If shims are not found on left side at disassembly, housing is the machined type and shims are not required). Adjust endplay by adding or removing shims (shims are .003", .005", .010", .030" thickness), from right side only.

Axle Shaft Endplay

Car Model	Endplay
Hudson	.001-.004"
Kaiser	.001- 006"
Studebaker	.003- 006"
Willys	.003-.007"

REMOVAL OF AXLE: *See "Rear Axle" on Car Model pages.*

OVERHAUL: *See "Spicer (Salisbury) Hypoid Semi-Floating Rear Axle" in Manual and note the following:*

►***PINION BEARING ADJUSTING SHIM CAUTION:*** On these axles shims are placed between front bearing cone and shoulder of pinion shaft.

Pinion Bearing Adjustment: Pinion bearing adjustment is made after pinion setting has been established, and pinion setting washer installed between rear bearing cone and pinion shaft gear, and before front oil seal installed.

Willys & Studebaker—With pinion shaft nut tightened to 150 ft lbs, pinion should rotate with slight drag and with no endplay. Adjust by removing front bearing cone and adding or removing shims between bearing cone and shoulder on pinion shaft.

Hudson—With pinion nut tightened to 200 ft. lbs. (180-200 ft lbs. Jet), use a spring scale on flange holding tool J-2637 and check torque required to turn pinion Turning torque should be 17-32 in. lbs. (10-20 in. lbs. Jet). Adjust by adding or removing shims between front bearing cone and shoulder on pinion shaft Shims are available in .003", .005", .010", .030" thickness.

Kaiser—With pinion nut tightened to 140-150 ft. lbs. torque, connect spring scale C-690 to one of the holes in companion flange or yoke, then, with pinion shaft in vertical position, rotate pinion by pulling on scale and note the reading. Torque should be 7-12 lbs. Adjust by adding or removing shims between front bearing cone and shoulder on pinion shaft. Shims are available in .003", .005", .010", .030" thicknesses.

Pinion Setting (Hudson All Models): ***(CAUTION—Hudson Jet pinion depth is different than other Hudson Models. See Pinion Depth table below).*** Using Pinion Setting Gauge No. J-5223 (consisting of gauge arbor and discs to fit differential bearing bores, clamps, and gauge block), determine pinion depth as follows: Mount discs on gauge arbor and install in differential bearing bores of axle housing. Place differential bearing caps in position and tighten

CONTINUED ON NEXT PAGE

SPICER HYPOID (Cont.)
MODELS 44 & 53

bolts finger tight. With gauge block held in position against end of drive pinion by clamp screw, loosen thumb screw in end of gauge block and move plunger out of block until head contacts gauge arbor, then lock plunger in place with thumb screw, using care not to disturb plunger position. Remove gauge block holding clamp and remove gauge block. Measure distance from anvil to top of gauge plunger. Reading on micrometer, for "0" pinion (pinion having a "0" mark, or one without a depth mark) should be same as indicated in table below, according to car model and gear ratio. For pinions marked (+) micrometer reading should be less; pinions marked (—) should be greater than the reading for "0" (standard pinions). Adjust pinion by adding or removing shims behind rear pinion bearing cup in housing and repeat test until correct micrometer measurement is secured.

Car Model	Axle Ratio	①Pinion Depth
Hudson Jet	4.10-1 (41-10)	2.250"
Hudson Jet	(Except Above)	2.343"
Hudson (Exc. Jet)	All	2.625"

①—Pinion Depth for "0" (Standard Pinion).

▷1953 Hudson Jet Pinion Setting Gauge Adapter (Part No. J-5223-50) Correction (for use on 4.1 ratio rear axles)—To permit checking distance between rear end of drive pinion and center of axle, drill out small stop pin (discard), remove plunger, and grind sufficient metal off small end of gauge to permit it to close up to dimension required (2.250").

Pinion Setting (Kaiser & Willys): Gauge No. W-99. Consists of dial indicator and fixture designed to be mounted on rear face of pinion (held in place by "C" clamp which is part of gauge). Gauge measures distance from face of pinion to differential side bearing bore in housing and dial reading should be ZERO before using this gauge (set with master gauge furnished with equipment). Set the dial indicator at ZERO with gauge pin resting on correct lobe of master gauge and with one-half turn tension on the gauge pin (master gauge table below). With pinion installed in axle housing (spacer Tool W-126-6 can be installed on pinion shaft in place of universal joint yoke), and with pinion setting gauge in place, dial reading should be ZERO for pinions marked "0", and should read PLUS (for pinions marked (+) or MINUS for pinions marked (—) by an amount equal to the figure following this + or — sign on the pinion. Adjust by adding or removing shims from behind rear bearing cup in housing, repeat test until correct reading secured.

Pinion Gauge Zero Setting

Axle Model	Master Gauge Lobe
44-2, 44-4	E
53-2	None

Pinion Setting (Studebaker): Pinion Setting Gauge Studebaker No. J-589-D.

▷*COMMANDER PINION SETTING CAUTION—The following setting for "0" pinions supersedes previous setting of .719" for Model 44 axles on 1951 & 1952 cars. Use Step Plate, Part J-589-10-2 for setting Model 44 Commander & President pinions.* Set micrometer gauge to correct figure for each axle model (see table below—this figure correct for pinions marked "0" on end) and correct micrometer for each pinion as follows: Figures etched on end of pinion indicates amount (in thousandths) that pinion should be set in toward ring gear (— figures) or out away from gear (+ figures). Install gauge in axle housing in place of differential assembly with side discs seated in differential bearing bores (different size discs used for Champion and Commander), add or remove shims located between rear bearing cup and shoulder in housing until micrometer pointer just contacts ground face of adapter. Pinion setting shims are .003", .005", .010" thick.

Axle Model	Pinion Zero Setting
44-3	.344"

Pinion Setting Note—The above "Pinion Zero Setting" figure should be corrected by ADDING (when pinions marked —), or SUBTRACTING (when pinions marked +), shim thickness equal in thousandths of inch to the figure stamped on the pinion immediately following the PLUS or MINUS mark.

Differential Endplay (All Models): The total amount of endplay in housing must be determined before installing drive pinion. Determine the total endplay as follows: Install side bearing cones on differential case (without shim packs), fully seating cones against differential case, then install bearing cups, and install differential assembly in axle housing. Mount dial indicator on axle housing with indicator contact button against back face of ring gear, and with two screw drivers, force differential case endwise as far as possible to seat bearing cup in housing. Adjust dial indicator to zero. Force differential case toward opposite end until bearing cup is seated in housing. Note reading on indicator. This reading indicates the shim thickness required to eliminate all differential endplay in housing.

Differential Bearing Preload & Gear Backlash Adjustment: With drive pinion installed and adjusted, adjust differential bearing preload and gear backlash as follows:

Hudson & Kaiser (All Models)—Install differential assembly (without shim pack) in axle housing. Install bearing caps and tighten bolts finger tight. Insert screw drivers and force differential assembly away from pinion until bearing cup is seated against housing, then force differential case in opposite direction until ring gear teeth contacts pinion teeth. From the endplay shim requirement (above), place shims between bearing cups and axle housing, forcing their edges in on both sides until total amount of shims have been used, and gears have no backlash. Remove differential assembly from housing (keeping shims for each side of case together). Remove side bearing cones and cups and install shims between cones and differential case, on their respective sides. Add an additional .015" shim on drive gear tooth side to give proper amount of housing spread and gear backlash. Spread axle housing with Spreader Tool W-129 (Henry J & Kaiser); J-5372 (Hudson), and install differential assembly, shims, bearing cones and cups, and install bearing caps in their original positions (Caps, bearings, & case marked at disassembly). Tighten bearing cap bolts to 70-90 ft. lbs. torque. Recheck ring gear backlash to following specifications:

Kaiser & Hudson (Exc. Hudson Jet)—.003-.006".

Hudson Jet—.002-.006".

Studebaker—Install differential assembly, (without shim pack), in housing. Mount a dial indicator on housing with indicator contact button resting against back face of ring gear. With two screw drivers, force differential assembly away from pinion until bearing cup is seated against housing. Set indicator to zero, then force differential assembly toward pinion until ring gear teeth contact pinion gear. Reading on dial indicator, less .003", denotes the shim pack required between differential case and bearing cone on ring gear side. Shims for the opposite side are determined by subtracting the amount of shims used on ring gear side from the total amount (determined above—see Differential Endplay), and adding .008", which provides the necessary bearing preload.

Backlash (Studebaker)—Mount dial indicator on housing with contact button against one of the ring gear teeth. Move ring gear by hand and check amount of backlash, which should be .003-.006". Adjust backlash by moving the necessary number of shims from one side of differential case to the other. (NOTE—Backlash will be changed approximately 2/3 of thickness of shims transferred).

Willys—Install differential assembly and side bearings (without shims) in axle housing. Force assembly to one side until bearing cups are seated in housing, then with a feeler gauge, measure the distance between opposite bearing cup and axle housing. After clearance has been determined, add .008" (to provide bearing preload). Remove differential side bearings from case and install one-half total thickness of shims on each side and replace bearings. Install housing spreader Tool W-129 and spread the axle housing about .020", and install differential case. Install bearing cups, and bearing caps. Tighten cap bolts to 38-42 ft. lbs. torque.

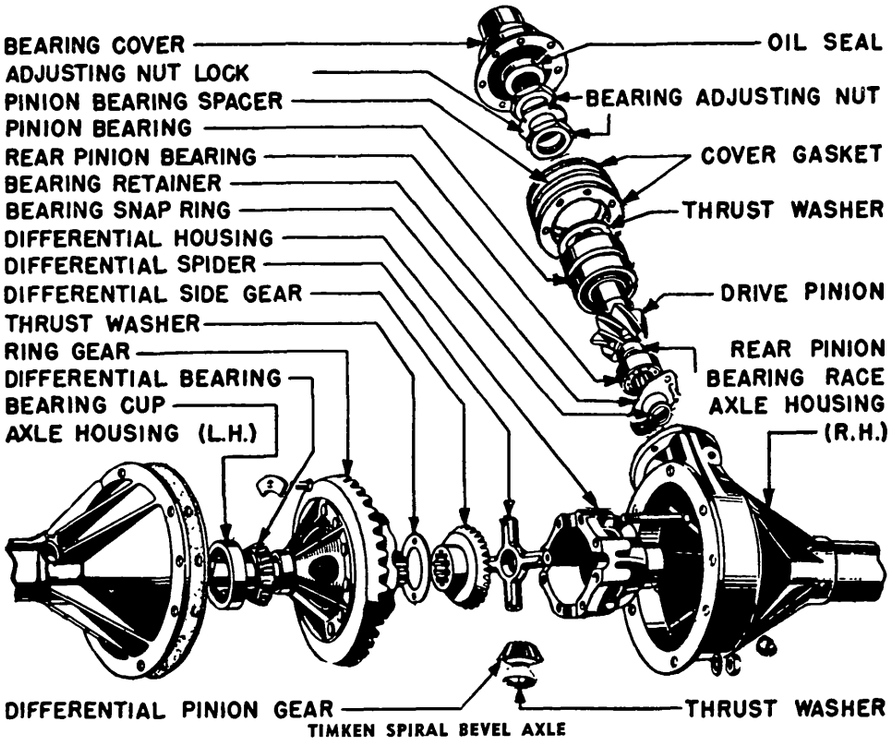
Backlash (Willys)—Mount dial indicator on axle housing with indicator contact button against corner of ring gear tooth. Check backlash, which should be as indicated in table below. Adjust by moving necessary number of shims from one side of differential case to the other. (NOTE—Backlash will be changed approximately .0035" by transferring a .005" shim to the opposite side).

Ring-and-Pinion Gear Backlash

Car Model	①Backlash
Kaiser	.003-.006"
Hudson Jet	.002-.006"
Hudson (Exc. Jet)	.003-.006"
Studebaker	.003-.006"
Willys (44)	.004-.008"
Willys (53)	.003-.006"

①—Movement of ring gear with pinion gear held stationary.

TIMKEN SEMI-FLOATING



TIMKEN MODEL NO. 51540
Willys, Truck, Models 2WD, 4WD (1947-50)
Willys, Truck, Model 473-4WD (1950-51)①
Willys, Truck, Model 475-4WD (1952-55)①
Willys, Truck, Model 6-226-4WD (1954-55)①

①–This axle used optionally with "Spicer Semi-Floating (Model 53-2)" Rear Axle since August, 1951.

DESCRIPTION: Spiral bevel, semi-floating type with Hotchkiss Drive. Axle housing is "split" type with one differential side bearing cup seated in recess in each half. Pinion is mounted on taper roller bearings in housing integral with right hand axle housing. Pinion bearing assembly is special type with a single outer race (bearing cup) for both roller bearings. Axle shafts are mounted on single taper roller bearing at each wheel, each bearing taking thrust in one direction while the thrust in the opposite direction is transmitted to the opposite bearing through the axle shafts.

AXLE SHAFT REMOVAL & WHEEL BEARING ADJUSTMENT: Same as for other Willys models. See Spicer Hypoid Semi-floating axle for complete data.

REAR AXLE DISASSEMBLY & REASSEMBLY: Remove eleven screws holding axle housing halves together, slide left housing half away (axle shaft will pull out of differential gear splines). Lift out differential assembly (pull out toward left so that right axle shaft is disengaged from differential gear splines). To remove side bearings, use Puller Tool No. W-104-20 to remove roller and cone assemblies from differential case shoulders, Tool W-200 to pull bearing cups from axle housing. To remove pinion assembly, take out bolts in housing holding bearing retainer (spacer) and cover, lift off cover and oil seal assembly, bearing retainer, and gaskets. Assemble Puller W-203 on end of pinion shaft, pull pinion and bearing assembly out toward front. See Pinion Assembly data below for disassembly of this unit.

TIMKEN SPIRAL BEVEL AXLE

Pinion Bearing Assembly: To dismantle this assembly, clamp pinion in vise (use brass jaws), bend up lips on locking washer, remove pinion locking nut, washer, and adjusting nut. Lift off front bearing cone and roller assembly, (slip fit on shaft), and bearing cup. Use Puller No. W-104-32 to remove rear bearing cone and rollers. To remove pinion bearing from housing, drive out two brass rivets in retaining plate from front of housing, remove plate, drive bearing out using a brass drift. To reassemble, install pilot bearing retainer, drive pilot bearing in place using Tool W-207, press pilot bearing inner cup on end of pinion shaft and install lockring (NOTE—New pinions furnished with cup and snap ring installed). Press rear pinion bearing cone and roller assembly firmly against pinion using Tool W-205, install bearing cup and front bearing cone and rollers, install washer, adjusting nut, locking washer, and locknut. Adjust pinion bearing pre-load (see below), securely tighten locknut and bend locking washer lip against nut. Install pinion assembly in housing using Installer Tool W-203. (CAUTION—Make certain pinion shaft enters pilot bearing in housing.) Check oil seal in pinion shaft cover (install new seal, if required, with Tool W-199). Install bearing retainer and cover assembly on housing using new gaskets (CAUTION—Align oil drain hole with opening in housing), install retainer bolts and tighten securely.

Pinion Bearing Pre-load Adjustm nt: With pinion bearings assembled on pinion shaft, tighten adjusting nut to preload bearings so that torque required to turn pinion shaft is 12-18 in. lbs. Locknut must be tight when checking this pre-load.

Pinion Setting: Pinion position is not adjustable. Ring gear and pinion are furnished only in matched sets and ring-and-pinion gear mesh will be satisfactory if axle correctly assembled and backlash is within limits of .004-.008".

Differential Assembly: To dismantle assembly for replacement of parts, cut lockwire, remove nine screws, separate differential case halves. Replace Differential Pinions, Pinion Thrustwashers, Side Gears, and Gear Thrustwashers as **matched sets.**
CAUTION—Use of mixed new and old parts will result in premature failure. Make certain that differential case screws are secured with lockwire when reassembling. Use Tool W-206 to install side bearing cone and roller assemblies on case, Tool W-204 to install bearing cups in housing. Before reassembling axle, examine ring gear thrust plate for wear and replace if necessary (plate is riveted in left hand housing)

Ring & Pinion Gear Backlash: .004-.018". Check backlash after axle completely reassembled.

1946-54 BUICK HYPOID

All Series (1946-54)

▷CHANGES, CAUTIONS, CORRECTIONS

▷*1953 REAR AXLE HOUSING PRODUCTION CHANGE CAUTION: (Two Different Housing & Carrier Assemblies Used Requiring Different Pinion Settings).* For identification and service procedures see "Overhaul."

▷*1953 PINION SHAFT OIL SEAL PRODUCTION CHANGE: See "Overhaul" for complete data.*

▷REAR AXLE LEAKAGE CAUTION: Oil leaks may occur at front pinion bearing unless following precautions observed:

Oil Leakage into Propeller Shaft (causing shaft unbalance)—Can be prevented by properly sealing pinion shaft when propeller shaft installed. *See Pinion & Propeller Shaft Assembly below.*

Oil Leakage into Torque Tube (and transmission)—Can be corrected by installing special oil seal in front of pinion front bearing. *See Pinion Bearing Oil Seal Installation below.*

Oil Leakage at Torque Tube & Housing Mounting Flange—Correct by disconnecting torque tube and installing new gasket (gasket is made of special material—DO NOT use any substitutes for this gasket).

▷*CAUTION*—Do not remove torque tube from carrier housing for any other reason than gasket replacement to correct oil leakage. These parts are matched and aligned during manufacture and are not furnished separately.

▷LATE 1948 PINION BEARING CHANGE: Late 1948 cars (1949-54) have two pinion roller bearings (rear bearing) installed side by side on rear end of pinion shaft. See data on these bearings below.

▷*IDENTIFICATION NOTE*—1948 axles with two pinion roller bearings stamped "BB" on bottom center of axle housing.

▷*REAR AXLE BREATHER PRODUCTION CHANGE:* A breather has been installed on the rear axle housing to eliminate the possibility of leakage. The new breather, Part No. 3700490 can be installed on axles not so equipped as follows: Remove left axle shaft, and ring gear. Drill a .359-.369" diameter hole on top of the housing approximately 14" from center line of carrier and drive breather into place *CAUTION*—Place a greased rag in axle housing to prevent any chips entering. Make sure that axle is clean of all foreign material before reassembling ring gear and axle shaft.

▷*1953 PINION BEARING OIL SCOOP PRODUCTION CHANGE:* On axles with 3.6-1 and 3.9-1 axle ratios (Rear Axle Housings With Wide Carrier) an oil scoop, Part No. 1391836 has been added to provide more positive lubrication. *When installing new gears or bearings n 1953 cars with the wide carrier, this scoop should als be installed* as follows: Remove differential ring assembly, pinion, and drive shaft, and wipe carrier housing dry. Insert lip of scoop in oil passage and rotate scoop toward the right side of the housing so hole in scoop is approximately on the center line of the two upper carrier bearing cap bolt holes. Note the position of top rib on front face of housing and try and line up hole in scoop so that when hole is drilled through housing, it will enter rib and not break through housing. With scoop in position, tilting downward toward oil passage hole, scribe the outline of the hole in scoop on carrier housing. Center punch this hole and with an 11/16" drill, drill a hole ½" deep, perpendicular to the housing surface (*CAUTION*—If hole breaks through case, be sure and coat threads of screw before installing). Tap screw hole with a 12-24 tap. Install pinion assembly and install the scoop. Reassemble ring gear assembly and check clearance between ring gear and scoop. Replace the old rear axle housing cover with Part No. 1391835 (having a filler plug and plug gasket).

DESCRIPTION: Hypoid gear, semi-floating type with torque tube drive.

REMOVAL OF AXLE: *See "Rear Axle" on Car Model pgs.*

AXLE SHAFT REPLACEMENT: Axle shaft retained by "C" washer at inner end. To remove axle shaft take out locking pin, remove differential pinion shaft and spacer block, push axle in and remove "C" washer at inner end within differential side gear, (use tool J-1515 to drive washer from shaft slot), pull shaft out (wheel bearing inner race is press fit on shaft and will be removed with it, outer race is light press fit in axle housing and can be removed with puller J-528-B Puller).

NOTE—Right hand axle shafts are longer than left hand shafts and must not be interchanged.

Axle Shaft Endplay—Controlled by spacer block between axle ends in differential case and should be .000" minimum, .008" maximum. Four block sizes used in production, replacement blocks ground on all sides for min. and max. production sizes.

Important—New bronze side gear thrust washers should be installed back of differential side gears before new axle shaft spacer block installed to correct excessive endplay.

PROPELLER SHAFT & FRONT BEARING: Propeller shaft is part of pinion & shaft assembly (see Overhaul data following).

▷*TORQUE TUBE CAUTION*—Torque tube is bolted to carrier but DO NOT DISTURB connection between torque tube flange and carrier flange unless installation of new gasket required to stop oil leaks (special gasket required). Torque tube and carrier are matched and aligned at factory.

OVERHAUL: After removal of axle shafts, differential side bearings and thrust washers.

▷*1953 REAR AXLE HOUSING & CARRIER PRODUCTION CHANGE:* New housing with wider ring gear saddles entered production March 1, 1953. Different pinion settings and Pinion Gauge rework required. Housing Identification—New type housing reinforcing ribs on forward side of housing are longer and extend from rear flange of housing to front torque tube flange (older type housing reinforcing ribs are shorter and terminate midway between the two flanges).

▷*1953 PINION SHAFT OIL SEAL PRODUCTION CHANGE:* Starting with March 16, 1953 production a new seal is used to provide positive piloting and to prevent cocking of seal. The pinion nut is also revised and can be used with either new or old type seals; however, OLD TYPE NUT CANNOT BE USED WITH NEW SEAL. New seal and nut are furnished in Kit, Part No. 1393999.

▷*1952 PINION & PROPELLER SHAFT REMOVAL NOTE (Dynaflow Drive cars & Synchro-mesh cars equipped with 3.6 or 3.9 ratio rear axles)*—It will be necessary to remove the rear axle in order to remove the propeller shaft and pinion. This will not be necessary on Synchro-mesh cars having 4.1 axle ratio, as a puller is available and the propeller shaft spline seal is not used.

▷*1953-54 PINION & PROPELLER SHAFT REMOVAL:* With the type seal used in these cars, it is possible to remove and replace pinion and propeller shaft without disconnecting from torque ball. CAUTION—Care must be taken when installing the propeller shaft with the axle in the car to start propeller shaft in through seal gently to avoid striking seal retainer, as damage will result. Press propeller shaft and pinion assembly into carrier, as driving it in can cause damage to front bearing.

▷*PINION PRESS, TOOL J-1292-E, REWORK (Supersedes Rework of Yoke Screws J-1292-36):* To use new type yokes, J-1292-40 and J-1292-41 which are wider than yokes previously furnished with press, it will be necessary to rework the press as follows: Remove the shoulders at each end of propeller shaft support (adjacent to tool side rails) so that surfaces of support between the support slot and the side rails are parallel to top of side rails. Weld casting to side rails and a point below support slot, both at front and rear of the support. *Do not weld upper surface of support at junction with side rails.* It is suggested that if Yoke Screws J-1296-36 were previously reworked, that new screws be secured. New yokes and screws are available in Conversion Kit J-1292-43.

Disassembly: Mark differential bearing caps so they can be installed in original positions. Remove bearing adjuster locks, loosen one adjuster, support differential gear and case assembly while removing bearing caps and adjusters, then lift differential assembly and bearing races out of carrier.

Pinion & Propeller Shaft Removal & Disassembly—(NOTE—Before removing pinion and shaft, the pinion shaft bearing wear can be determined by mounting a dial indicator, with 1¼" extension, to bear vertically against center drilling in pinion gear. Pry up on pinion gear with a bar a number of times and check indicator reading. Reading should be less than .0015". If greater, the bearing is worn and should be replaced). Loosen locknuts and remove three pinion bearing sleeve screws from housing. Pull pinion and shaft assembly, using Pinion Shaft Puller. Remove all pinion bearing shims from propeller shaft and third member housing to prevent damage. Mark pinion and propeller shaft so that parts are reassembled in same position. File or cut off end of propeller shaft coupling pin and drive out pin, then pull propeller shaft from pinion using Press J-1292-E. Drive up staked section of pinion bearing lock nut with cape chisel, and remove nut, gripping pinion shaft on splined end in vise. Do not grip pinion gear in vise, even though soft jaws are used. Press off pinion front bearing using blocks under outer race of bearing, then remove all other parts from pinion shaft. NOTE—The double row front bearing is preloaded and will have a slight drag when installed on pinion.

Pinion Shaft Reassembly & Installation—Install parts on pinion shaft in following order: rear bearing spacer, two rear bearings, bearing lock sleeve

CONTINUED ON NEXT PAGE

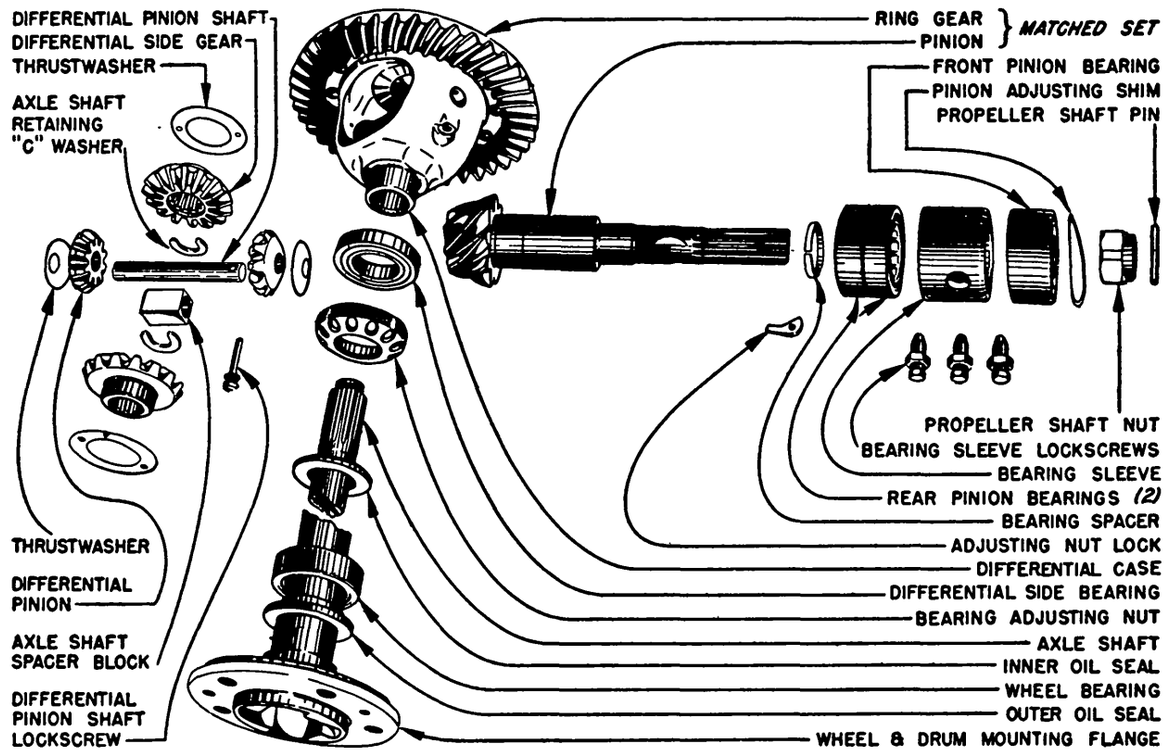
1946-54 BUICK HYPOID (C nt.)

with chambered end toward spline, front bearing with shielded side toward spline. Press front bearing solidly against shoulder on pinion shaft, using a tube of proper size to bear against inner race only. Make certain that outer surface of pinion bearing lock nut is clean and free of nicks or burrs, then install new bearing oil seal with spring loaded edge pointing away from hex nut. Install lock nut on pinion with seal toward ball bearing. While gripping splined end of pinion in vise (with soft jaws), tighten nut to minimum of 150 ft. lbs. torque. Stake outer edge of lock nut down into notch in pinion. Push oil seal flat against bearing. Coat splined end of pinion with white lead, then press pinion into propeller shaft until coupling pin holes are aligned, using Press J-1292-E. Pinion must not be a loose fit on shaft. Install a new coupling pin and solidly rivet both ends. ***CAUTION—Whenever a pinion and propeller shaft are assembled together the complete assembly must be checked for straightness. See "Propeller Shaft Runout" below.***

Installation—Place original number and thicknesses of pinion bearing shims over propeller shaft and against front bearing. Use axle lubricant to thoroughly lubricate bearing and to coat outer surfaces of oil seal. As pinion and shaft assembly is inserted into third member housing, turn pinion front bearing outer race so that ball loading groove will be straight up. As pinion bearing enters third member housing, place pinion bearing spacer (see note below) between bearing and pinion gear so that bearing can be pushed into place without binding against spacer on pinion. Push pinion into housing until shims and front bearing are seated, using a jack or other means of applying steady pressure to avoid possibility of damaging front bearing. Align holes in bearing lock sleeve with tapped holes in carrier and install three sleeve lock screws. Tighten each lock screw just a little at a time until lock sleeve and pinion front bearing are solidly seated and screws are uniformly tightened to 35-40 ft. lbs. torque. Tighten lock nuts to 15-20 ft. lbs. torque; excessive tightening of lock screws may withdraw lock screws sufficiently to allow end play of pinion bearing. Check pinion setting. See "Pinion Setting" below.

►***CAUTION—Unless new thrust washers used, new spacer block alone will not secure correct .008" max. endplay (if old washers worn).***

Pinion Bearing Assembly:—Bearings should be press fit on pinion shaft (use tubing of correct diameter to engage inner race when pressing bearings on shaft). No inner race used for rear pinion bearing (outer race and rollers furnished as assembly) and spacer must be installed between rollers and pinion to prevent creeping. Tighten pinion bearing nut securely and stake into notch on shaft. Assemble pinion to propeller shaft riveting pin to prevent it loosening in service (see propeller shaft straightening below). When installing assembly in housing, tap outer race of rear bearing in against shoulder in housing or against bearing collar to prevent the race rubbing on pinion (use Pinion Bearing Spacer J-1192-B or J-5499—See Note below). Make certain that adjusting shims installed ahead of front bearing, tighten setscrews and locknuts securely.



Pinion Rear Roller Bearings—Clearance between bearing rollers and pinion shaft should be .0005" (desired), .0014" (maximum allowable). Check bearings for wear by measuring thickness of roller and outer race at four or five points around bearing (use a micrometer and make certain bearing is absolutely clean). Micrometer reading should be .6756" min., .67605" max. Replace bearing if less than .6756". Bearing can also be checked for wear by using paper strip .0015" (measure with micrometer) between pinion shaft and one roller of the bearing. Bearing should hang on paper strip and strip should not pull out (if bearing drops off strip of own weight or if strip can be pulled out, bearing should be replaced. **Pinion Bearing Spacer Tool Note**—Consists of a horseshoe shaped spacer which should be inserted between pinion and rear bearing when tapping on face of pinion to seat bearings in carrier (use bronze driving block on pinion, remove tool after installation completed), Spacer tool is No. J-1192-B (1946-Early 1953 with First type pinion gear), J-5499 (Late 1953-54 with later type pinion).

►**Pinion Sealing Note**—Splined joint must be sealed to prevent lubricant entering propeller shaft and causing unbalanced condition. Seal shaft by dipping end in Presstite Sealer (Permatex or white lead may also be used) before assembling propeller shaft. Pinion shaft MUST NOT be a loose fit in propeller shaft.

Propeller Shaft Run-out: ***Assembly must be checked for straightness whenever pinion and shaft installed regardless of whether new or old parts used.***

Checking & Straightening (Using V-blocks)—Support pinion and shaft assembly on V-blocks at each end (forward block just to rear of splines at forward end of shaft, rear block under pinion rear roller bearing race). Use dial indicator to measure run-out at points 3" in from each end of shaft tube (CAUTION—do not allow unevenness of tube surface to cause indicator to bounce indicating wrong reading). If run-out not within .005" at these two points, straighten tube by exerting pressure on center of tube (support tube at same point at front end and under bearing lock sleeve at rear for straightening). Then check run-out at center of shaft tube. If run-out exceeds .010" at this point, straighten tube while supporting it on blocks at tube weld point at each end. Then check run-out at pinion front ball bearing. If run-out exceeds .001", support shaft at forward V-block and at bearing lock sleeve at rear end, exert pressure at weld points on rear end of tube. Recheck all run-out points, then check run-out at extreme forward end

CONTINUED ON NEXT PAGE

BUICK HYPOID DIFFERENTIAL GEAR & PINION ASSEMBLY

1946-54 BUICK HYPOID (Cont.)

of shaft. Run-out at this point should be less than .002" total indicator reading.

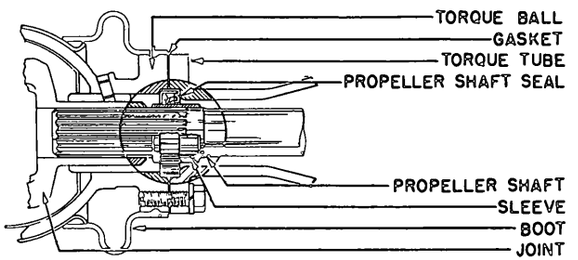
▷*CAUTION—More than .002" run-out at forward end of shaft will cause rapid wear of universal joint bushing and possible leakage of transmission case lubricant into rear axle.*

Pinion Bearing Oil Seal Installation: This oil seal furnished in kit, Part No. 1393999 (seal and special pinion nut), and can be installed on all 1940 and later cars to correct oil seepage from rear axle into torque tube or propeller shaft. Installation of oil seal on 1950 and previous cars requires fitting of the seal as follows:

1946-50 Cars—Fitting of the seal will be easier if holding tool made up of 3 1/16" diameter hardwood block approximately 14" long with 2 7/8" circular depression 1/16" deep on end used (place seal in recess, use wood screw and 2" diameter washer to hold seal in place on end of block). Drive seal lightly into carrier bore (CAUTION—do not use excessive force). If seal will not start in carrier bore, reduce outside diameter of seal slightly by light filing or emery cloth (CAUTION—remove all filings and emery dust by thorough washing). After seal driven into carrier bore, remove and check for proper fit (outer surface should show light scratch marks evenly around entire circumference). If seal loose (not marked as above), expand seal by denting bead on rear side at six evenly spaced points using a light hammer (CAUTION—retain original bead height as much as possible since bead spaces seal from front bearing shield). After seal properly fitted, install seal on pinion nut with lip of leather seal pointing away from hexagonal portion of nut. Assemble pinion and propeller shaft in usual manner.

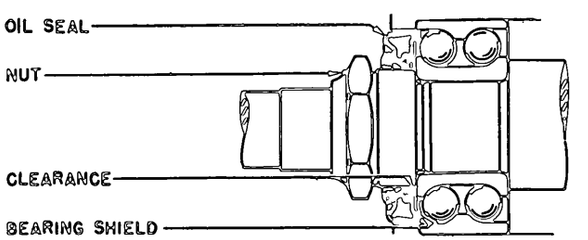
CAUTION—If seal has been fitted by denting bead, apply sealing compound (Permatex No. 2) to outer surface and allow to dry until gummy just prior to final installation of assembly in carrier Avoid excessive use of sealer (must not be allowed to get down between shims and affect pinion position).

1951-54 Cars—Make certain that outer surface of pinion bearing locknut is clean and free of nicks or burrs, then install new bearing oil seal with spring-loaded edge pointing away from hexagonal portion of nut. Assemble pinion and propeller shaft in usual manner.



Ring Gear Installation: Ring and pinion gears furnished in matched sets only.

Ring Gear Replacement—To remove old gear, drill old rivets ½" deep with ¼" drill on ring gear side, drive rivets out with a punch inserted in drilled hole. Check gear mounting face of case for burrs, check run-out which must not exceed .002". Mount new ring gear on case with 11 5/16" x 1½" bolts with 3/8" SAE nuts placed in rivet hole counterbores to act as spacers. Check bolted assembly for runout with dial indicator on back face of ring gear. If run-out less than .003", use Riveting Jig J-2196-A to install rivets. Use correct rivets (which allow 5/16" shank length for heading), install rivets from gear side, use 8 tons pressure to head rivets cold. Install rivets in diametrically opposite progression, removing only one bolt at a time. Recheck run-out after all rivets installed. Run-out must not exceed .003".



▷*PINION SETTING GAUGES J-2197, J-681-A, & ADAPTER J-2197-9 REWORK FOR USE WITH 1953 & 1954 REAR AXLE ASSEMBLIES (WITH WIDE SADDLE CARRIERS):* Adapter J-2197-9 Rework—Increase width of the cavity cast into the adapter from 2" to 2⅜".

Pinion Setting Gauges J-2197 & J-681-A Rework: Remove the collar on the short side of the cross bar and increase the depth of the counterbore ¼". Replace collar on cross bar.

Pinion Setting (Using J-681-A Pinion Setting Gauge): Pinions marked on rear face of two teeth by an etched figure and plus or minus sign for necessary correction of standard setting (micrometer reading for standard settings given below). Plus sign indicates that pinion should be moved away from axle shaft center-line, minus sign toward axle center-line, the amount (in thousandths) of the figure following this plus or minus sign. Use J-681-A Pinion Setting Gauge, check micrometer '0' on test fixture, set micrometer to standard figure (as given in table below for each model, turn micrometer pointer in (for plus figure) or out (for minus figure) the amount stamped on face of pinion, install gauge in axle housing (with differential carrier removed) seating gauge rings on differential bearing posts, add or remove shims (furnished in .001" steps from .010" to .019" thick) between pinion front bearing and shoulder in housing. Center adapter on end of pinion and rotate it so the ground indicating surface is to the left of the pinion vertical center line so that the micrometer contacts the center portion of the surface when it is swung through its arc. Use gauge adapter J-681-37-1 with pinions mounted in narrow saddle carriers. Use gauge adapter J-2197-9 (reworked—see above) with pinions mounted in wide saddle carriers. The reworked gauge adapter J-2197-9 must be held in position with clamp supplied in Pinion Setting Kit J-2197-15.

1953-54 PROPELLER SHAFT SPLINE SEAL

1951-54 PINION SHAFT OIL SEAL

Standard Pinion Setting①
(Gauge J-681-A)

Model	Gauge Setting
1946-52	.379"
1953 (Early Type)	.379"
1953-54 (Later Type)	.317"

①—Nominal setting for "O" pinion gear.

Pinion Setting (Using J-2197 Pinion Setting Gauge:

▷*NOTE: See "Pinion Setting Gauges Rework" above for 1953-54 pinions mounted in wide saddle carriers.*

This new type gauge similar to previous type, J-681A, except that micrometer scale markings are reversed. This gauge is used in same manner as previous type (gauge rings seated in side bearing bores, micrometer set so that pointer contacts adapter plate on face of pinion gear) except that "nominal" or standard readings are new (see below) and that corrections for pinions marked (+) must be added, and corrections for pinions marked (—) must be subtracted from the nominal micrometer reading when this J-2197 gauge is used.

▷1946 (& Later) Pinion Setting Note—Pinions are ground on face and one gauge reading will be sufficient to check pinion setting (not necessary to "average" two readings as for previous type).

Standard Pinion Setting①
(Gauge J-2197)

Model	Gauge Setting
1946-52	.802"
1953 (Early Type)	.802"
1953-54 (Later Type)	.864"

①—Nominal setting for "0" pinion gear.

Differential Bearing Adjustment:—Remove adjusting nut locks, mark adjusting nuts, loosen right bearing capscrews ¾ turn and tap cap lightly to free nut, back off right hand nut slowly and note point where bearing race stops turning with nut, mark this new position, return nut to original position and repeat check. Race should stop turning at same point and number of notches nut has been turned is 'notches tight' of old setting. Correct setting is 2½-3 notches tight (1946-Early 1953 with First type housing and carrier), 2-3 notches tight (1953-54 with Later housing and carrier) with the adjusting nut turned in this amount from the free position noted above. Tighten both bearing nuts securely, check ring gear backlash. After all adjustments, install adjusting nut locks.

Ring & Pinion Gear Adjustment: Check pinion setting (see instructions above) or paint gears to check mesh. Backlash should be .006-.011" for new gears (slightly more for worn gears) with .007-.009" preferred. Lash must not vary more than .003" around the ring gear. If original gear set is being installed, original gear lash should be maintained.

Ring Gear Backlash Adjustment. When adjusting ring gear backlash, make certain that differential side bearing adjustment not disturbed (back off one nut and tighten opposite nut equally). Check bearing adjustment. If adjusting nuts marked before dismantling, setting nuts up to original marks should give correct ring gear position.

NOTE—Backing off one nut and tightening other nut one notch will change backlash approximately .0035".

BUICK REAR SUSPENSION

All Series (1946-55)

DESCRIPTION: Coil spring type.

TRIM DIMENSION: Before measuring rear spring trim dimensions, bounce rear end of car up and down several times to make certain suspension is not binding and to allow springs to assume natural position. Then measure from top of axle housing to top of bumper clip on frame side rail to rear of bumper. If trim dimension not correct with car at curb weight, replace spring.

TRIM DIMENSIONS
(Heights are for Standard Springs)

1948 Models	Height
40	5½-6¼"
50, 70	6½-7¼"
1949 Models	**Height**
56C, 76C	5 9/16-6 5/16"
All Others	5 13/16"-6 9/16"
1950 Models	**Height**
56C, 75R, 76C, 76R	5½-6¼"
56R, 59, 79	5⅝-6⅜"
All Others	5 13/16"-6 9/16"
1951 Models	**Height**
46C, 56C, 76C, 76R	5½-6¼"
56R, 59, 79	5⅝-6⅜"
All Others	5 13/16"-6 9/16"
1952 Models	**Height**
46C, 56C, 76C	5½-6¼"

All Others	5 13/16"-6 9/16"
1953 Models	**Height**
46C, 56C, 76C	5⅝-6⅛"
59, 79R	5¾-6¼"
76X	5-5½"
All Others	5 15/16-6 7/16"
1954 Models	Height
46C, 56C, 76C, 100	5¼-6"
All Other Models	5½-6¼"
1955 Models	Height
46C, 46R, 56C, 56R, 66C, 66R, 76C, 76R	4¼-5¼"
All Other Models	5½-6½"

REAR AXLE RADIUS ROD: Radius rod need not be removed for rear axle removal (disconnect rod at right hand end) but should be removed and checked for straightness and twist when new bushings installed.

Removal—Support rear end of car on jacks under axle housing so that weight of car is on springs. Take off nuts and washers on radius rod pins (at each end of rod), remove pin support at right end and frame bracket brace (pin support on 40 series) at left end of rod. Remove rod and bushings from pin on frame bracket.

Installation—Reverse removal procedure, using new rubber bushings. **Car weight must be on rear springs when tightening pin nuts** (to insure that rubber bushings will be clamped in neutral position).

REAR AXLE STRUT ROD REPLACEMENT CAUTION: Replacement torque tubes are furnished without holes drilled for strut rod rivets in the mounting bracket. Drill these holes only after rear axle housing, torque tube, and strut rods have been assembled. With strut rods in normal position (without up or down strain), drill bracket to match holes in strut rod with ½" drill, then drill through strut rods and bracket with 9/16" drill, install No. 1312923 bolts with lockwashers and thin nuts.

SPRING SPECIFICATIONS: Special 200 lb. and 500 lb. Overload Rear Springs are available for use with trailers or when heavy loads carried in car.

NOTE—To determine overload, weigh rear end of car at curb weight (no load except full fuel tank and spare tire and wheel in trunk), attach trailer and re-weigh rear end (difference is Overload).

►*CAUTION—Manufacturer does not recommend overloading rear axle in excess of 500 lbs.*

1955 BUICK HYPOID

ALL SERIES (1955)

►CHANGES, CAUTIONS, CORRECTIONS

►*RING GEAR & DIFFERENTIAL CASE PRODUCTION CHANGE:* Early type ring gear is riveted to differential case. Later type is bolted to case, using 12 special 3/8"-24, 300M bolts *(CAUTION—These bolts should not be replaced with any other kind under any circumstances).* The special bolts are identified by six straight lines around bolt head center and in some cases a manufacturers trade mark may also be in center of head. If the bolted type ring gear used to replace early riveted type, the differential case must also be replaced. *DO NOT rework the old case for use with the new ring gear.*

►*1955 DOUBLE ROW RADIAL THRUST BALL BEARING INSTALLATION ON EARLIER MODEL CAUTION:* The new oil seal, Part No. 1339437 must be used to avoid interference with nut hex when bearing, Part No. 954919 is used.

►*REAR AXLE HOUSING FILLER PLUG BREAKING CORRECTION:* Plugs will break if over-torqued. Tighten plug to 20-30 ft. lbs.

►*REAR AXLE CARRIER PRODUCTION CHANGE:* Carrier bolting flange has been increased in thickness from .620" to .800", and reinforcing ribs have been extended to the outer circumference of the bolting flange. Carrier attaching bolts (to rear axle housing) have been eliminated and studs, pressed into housing,have been substituted.

►*PINION GEAR PRODUCTION CHANGE:* A new tapered gear (tapered on back of pinion) replaces the early type. A new spacer also entered production at the same time to compensate for changes in pinion.

►*PINION GEAR INSTALLATION IN CARRIER CAUTION:* Different pinion bearing spacer tools are required for early and later type (tapered) pinion installation. *See "Pinion & Propeller Shaft Installation" below.*

►*PINION BEARING REPLACEMENT CAUTION:* If the 1955 bearing arrangement (one rear roller bearing) is to be installed in a rear axle in which the old arrangement (double rear roller bearing) has previously been run, *a new gear set MUST be used.* The ridge formed between the two radial bearings would cause rapid wear of the new single bearing.

DESCRIPTION: Hypoid gear, semi-floating type with torque tube drive. The pinion is supported in carrier by one roller bearing (rear), and a double row radial thrust ball bearing (front).

REMOVAL OF AXLE: *See "Rear Axle" on Car Model pages.*

AXLE SHAFT REPLACEMENT: Raise rear of car and place on stands. Clean rear end of chassis and all parts surrounding axle housing. Remove wheel and brake drum, drain rear axle housing and remove cover. Remove side pinion shaft lock screw and push pinion shaft from differential case, and remove spacers and pinions. Push axle shaft inward and drive the horseshoe shaped washer from grooved inner end of axle shaft, using tool J-1515. Support axle shaft while pulling it out of axle housing to avoid damaging bearing oil seals. *CAUTION—Do not allow axle to rest on oil seals during repairs.*

Axle Shaft Endplay: Controlled by spacer block between axle ends in differential case. Endplay should be .000" to .008" maximum. Replacement spacers are furnished standard size, and in two oversizes, each spacer having two dimensions for selective fitting. Install spacer between axle shafts and with both shafts pulled out as far as possible, check clearance between axle and spacer. If clearance exceeds .008", turn spacer ¼ turn and test clearance again. If unable to adjust endplay to .008", replace spacer with an oversize, or install new bronze thrust washers between side gears and differential case.

Wheel Bearing & Seal Replacement: After removal of axle shaft, disconnect link from shock absorber arm. Disconnect brake pipe from wheel cylinder and plug openings. Remove entire brake assembly from axle, supporting brake out of way to prevent damage to brake cable. Remove outer seal and roller bearing, then remove inner oil seal, using Remover J-1436 (sliding hammer & puller). If inner bearing race on axle shaft is to be replaced, grind part way through race and split it off shaft. Press a new bearing race into place against shoulder on shaft. Drive a new inner seal squarely and lightly into axle housing using care to avoid distorting seal. Install bearing into housing by tapping with a light drift on alternate sides of bearing *(CAUTION—Do not tap on rollers).* Install new seal and complete installation by reversing removal procedure.

PROPELLER SHAFT & FRONT BEARING: Propeller shaft is part of pinion & shaft assembly. *See "Overhaul" below.*

►*TORQUE TUBE CAUTION: Torque tube and carrier flanges are matched and aligned at the factory and should not be disturbed except for installation of a new gasket (to prevent leakage) or for replacement of either of the two parts.*

OVERHAUL: After removal of axle shafts, differential side bearings and thrust washers, proceed as indicated below:

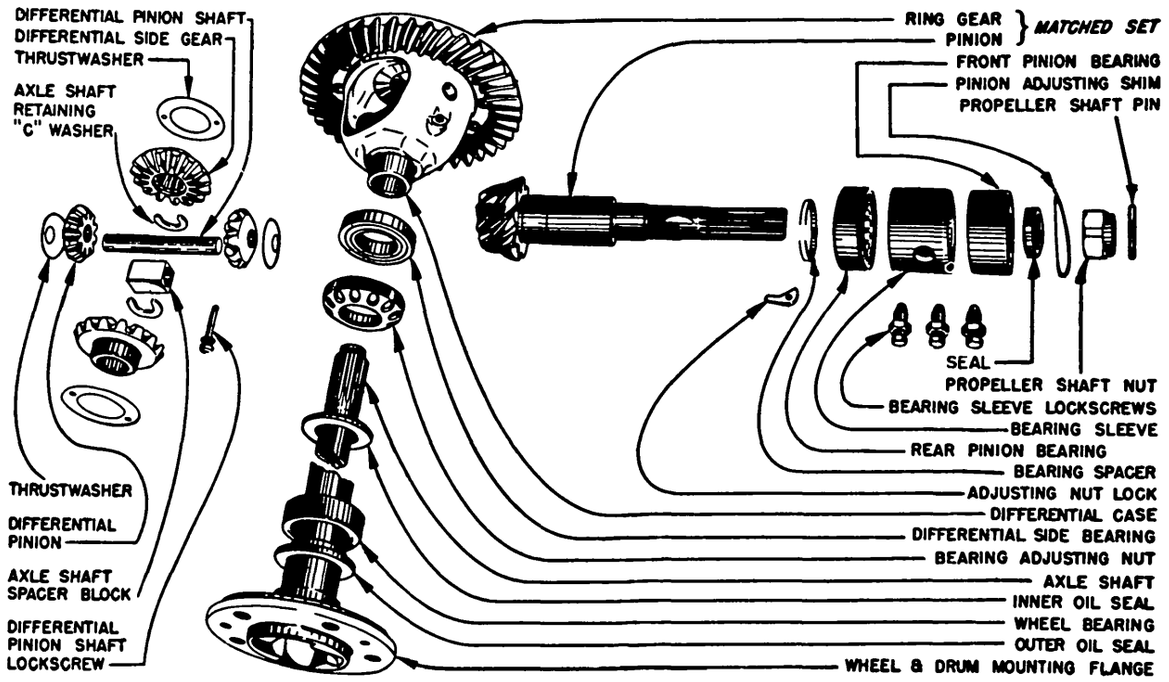
►*RING GEAR & DIFFERENTIAL CASE PRODUCTION CHANGE:* Early type ring gear is riveted to differential case. Later type is bolted to case, using 12 special 3/8"-24, 300M bolts *(CAUTION—Thes bolts should*

CONTINUED ON NEXT PAGE

1955 BUICK HYPOID (Cont.)

not be replaced by any other kind under any circumstances). The special bolts are identified by six straight lines around bolt head center and in some cases a manufacturers trade mark may also be in center of head. If bolted type ring gear is used to replace the early riveted type, the differential case must also be replaced. *DO NOT rework the old case for use with the new ring gear.*

►*REAR AXLE CARRIER PRODUCTION CHANGE:* Carrier bolting flange has been increased in thickness from .720" to .800", and reinforcing rubs have been extended to the outer circumference of the bolting flange. Carrier attaching bolts (to rear axle housing) have been eliminated and studs, pressed into axle housing, have been substituted.



►*PINION GEAR & SPACER PRODUCTION CHANGE:* A new tapered gear (tapered on back of pinion) replaces the early type. A thicker spacer is used with the new gear to compensate for changes in design.

►*PINION GEAR INSTALLATION IN CARRIER CAUTION:* Different pinion bearing spacer tools are required for early and later type (tapered) pinion installation. *See "Pinion & Propeller Shaft Installation" below.*

►*PINION BEARING REPLACEMENT CAUTION:* If the 1955 bearing arrangement (one rear roller bearing) is to be installed in a rear axle in which the old arrangement (double rear roller bearing) has previously been run, *a new gear set MUST be used.* The ridge formed between the two radial bearings on the old shaft would cause rapid wear of the new single bearing.

Disassembly: *(NOTE—Before removing differential assembly, check the gear lash with a dial indicator. See "Differential Case, Ring Gear, & Bearing Installation" below).* After removal of both axle shafts, remove differential side gears and thrust washers from case. Mark differential bearing caps so they can be reinstalled in original positions on carrier. Mark both differential bearing adjusters for location, then remove locks and check the bearing adjustment *(See "Reassembly" below).* Remove ring gear and case assembly from carrier, keeping each bearing race with its original bearing.

Pinion & Propeller Shaft Removal & Disassembly—*(NOTE—*Before removing pinion and shaft, the pinion shaft wear can be determined by mounting a dial indicator, with 1¼" extension, to bear vertically against drill center in pinion gear. Pry up on pinion gear with a bar a number of times and check indicator reading. Reading should be less than .0015". If greater, the bearing is worn and should be replaced). Loosen locknuts and remove three bearing sleeve screws from housing. Pull pinion and shaft assembly, using Pinion Shaft Puller J-5502. Remove all pinion bearing shims from propeller shaft and carrier housing to prevent loss or damage. Mark pinion and propeller shaft so that parts can be reassembled in the same relative position. File or cut off end of propeller shaft coupling pin and drive out pin, then pull propeller shaft from pinion using Press J-1292-C. Drive up staked section of pinion bearing lock nut and remove nut, gripping pinion shaft on splined end in vise. *Do not grip pinion gear in vise even though soft jaws are used.* Press off pinion front bearing using Bearing Remover Plates J-5737-6 installed in Press Plate Holder J-358-1 with recessed side upward. *NOTE—*The double row ball bearing will have a slight drag when installed on pinion due to being preloaded.

BUICK HYPOID DIFFERENTIAL & PINION GEAR ASSEMBLY

Differential Case, Ring Gear, & Bearings—*(NOTE—Early type ring gear is riveted to case. Later type is bolted. See Production Change above).* Remove all bolts from ring gear (if bolted type) and separated gear from case. If necessary to replace early (riveted type ring gear) type ring gear, drill ½" hole into rivets using a ¼" drill **on ring gear side,** drive out rivets with a punch inserted in drilled hole. Check gear mounting face for burrs around bolt holes and remove burrs with a mill file. Mount case in differential carrier with a dial indicator set to check runout of machined flange surface. If runout exceeds .002", flange must be trued up. To remove differential bearings, pull bearings from case using Puller J-2241 (the ends of puller fit into notches in differential case so that pressure can be applied to bearing inner race). DO NOT PULL ON ROLLERS.

Reassembly: *NOTE—Propeller shaft & pinion gear assembly must be checked for runout whenever pinion and shaft installed regardless of whether new or old parts used.*

►*RING GEAR & DIFFERENTIAL CASE PRODUCTION CHANGES: See Production Change above for installation of later type assembly on early models.*

Differential Case, Ring Gear, & Bearings—Check matching numbers on new ring gear and pinion (if being used). Bolt gear to differential case (if later bolter bolted type) using 12 special 3/8"-24, 300M bolts, Part No. 186627 *(these bolts are identified by six radial lines around bolt cent er).* Install bolts **with ut lockwashers** and tighten bolts on opposite sides of case to 25-30 ft. lbs., then tighten in same manner to 50-60 ft. lbs. On early type (riveted ring gear), use Riveting Jig J-2196-A to install rivets. Use correct rivets which allow 5/16" shank length for heading. Install rivets from ring gear side and use 8 ton pressure to head rivets cold. Install rivets in diametrically opposite positions until all rivets are installed. Recheck gear runout after all rivets installed. Examine bearing seat on differential case for burrs or scores and remove all high metal with a mill file. Coat bearing seat with engine oil or white lead and install bearing using Replacer J-2242, which is designed to pilot in the case and bear squarely against bearing inner race. Press bearing into position (do not hammer it in).

Pinion & Propeller Shaft Reassembly—Install parts on pinion shaft in the following order: Rear bearing spacer (small O.D. spacer with early type pinion, and large O.D. spacer with later "tapered" pinion), rear roller bearing, bearing lock sleeve *(with thin edge toward roller bearing),* and front ball bearing (with ball loading groove toward spacer). Press front bearing solidly against shoulder on pinion using Bearing Replacer Plate J-5737-7 in Plate Holder J-358-1 *(CAUTION—Do not hammer bearing into place as Brinelling will result).* Make certain that outer surface of bearing locknut is clean and free of nicks and burrs, then install

CONTINUED ON NEXT PAGE

1955 BUICK HYPOID (C nt.)

a new bearing oil seal with spring loaded edge pointing away from hex on nut. Install locknut on pinion with seal toward ball bearing. While gripping **splined end** of pinion in vise (with soft jaws), tighten nut to a minimum of 150 ft. lbs. Stake outer edge of locknut down into notch in pinion and push oil seal flat against bearing. Coat splined end of pinion with white lead to facilitate assembly, then press pinion into propeller shaft until coupling pin holes are aligned, using Press J-1292-C and correct yokes. Make sure that pinion is a tight fit in propeller shaft. Install a new coupling pin and solidly rivet both ends.

Ch cking & Straight ning (Using V-blocks)—Support pinion and shaft assembly on V-blocks at each end (forward block just to rear of splines at forward end of shaft, rear block under pinion rear roller bearing race). Use dial indicator to measure run-out at points 3" in from each end of shaft tube *(CAUTION*—do not allow unevenness of tube surface to cause indicator to bounce indicating wrong reading). If run-out not within .005" at these two points, straighten tube by exerting pressure on center of tube (support tube at same point at front end and under bearing lock sleeve at rear for straightening). Then check run-out at center of shaft tube. If run-out exceeds .010" at this point, straighten tube while supporting it on blocks at tube weld point at each end. Then check run-out at pinion front ball bearing. If run-out exceeds .001", support shaft at forward V-block and at bearing lock sleeve at rear end, exert pressure at weld points on rear end of tube. Recheck all run-out points, then check run-out at extreme forward end of shaft (must be less than .002").

►*CAUTION: More than .002" run-out at forward end of shaft will cause rapid wear of universal joint bushing and leakage of transmission oil into rear axle.*

Pini n & Prop ll r Shaft Installation—*(CAUTION—Two different pinion shafts and gear assemblies used during production. Different spacer tools are required for correct installation of the pinions. See "Production Changes" above).* Before installation of pinion and propeller shaft assembly make sure that all parts are clean and dry and that bearing shims are not crimped or buckled. Place the original number and thickness of pinion bearing shims over propeller shaft and against front bearing. Use rear axle lubricant to thoroughly lubricate bearings and coat outer surface of oil seal to aid installation. Lightly coat shims to hold them in place. As pinion and propeller shaft assembly is inserted into carrier, turn propeller shaft to engage splined front end in universal joint *(CAUTION*—Be very careful to start shaft through front seal in torque tube without damaging the seal retainer. If axle assembly is under car, the universal joint yoke will guide propeller shaft so that sleeve will enter seal centrally. If axle is not under car, a second man should guide shaft as sleeve enters seal. As pinion bearing enters carrier, place spacer tool (J-5905 for first type pinion, and J-5973 for second type "tapered" pinion. *See "Production Changes" abov),* between bearing and pinion gear. These spacer tools allow bearing to be pushed into place without binding. Mount Replacer J-5502 on carrier and press shaft and pinion forward until shims and front bearing are firmly seated. Align holes in pinion bearing lock sleeve with tapped holes in carrier and install the three sleeve lock screws. Tighten each lock screw a little at a time until lock sleeve is solidly seated and screws are uniformly tightened to 35-40 ft. lbs. Tighten lock nuts to 12-15 ft. lbs. *(CAUTION*—Excessive tightening of locknuts will cause lock screws to withdraw sufficiently to allow end play of pinion bearing). Remove spacer tool J-5905 or J-5973.

Differential Case, Ring Gear & Bearing Installation—Mount ring gear and case assembly in carrier with a dial indicator set to check runout of gear. Runout should not exceed .003'. Correct as necessary. Place outer races on differential bearings but do not oil bearings as this would interfere with bearing adjustment. Install gear and case assembly and slide bearing adjusters into position so that threads are properly engaged in threads in carrier pedestal. Install bearing caps with bolts, *(CAUTION—Make sure that caps are installed in original position marked before removal).* Turn bearing adjusters to engage threads. Tighten cap bolts to 20 ft. lbs., and then back off bolts ¼ turn. Using Adjuster Wrench J-1365-A turn adjusters as required to set ring gear lash at approximately .010" with both adjusters in contacts with bearings. *(CAUTION—Do not use punch and hammer to turn adjusters as this will distort adjusters and a proper bearing adjustment cannot be made).* Back off one adjuster (preferably the left) while observing bearing rollers and outer race, until rollers and race just stop turning, then tighten adjuster 4 to 5 notches to properly seat bearings and adjusters. Slowly back off adjuster until bearing outer race just stops turning. Recheck for this "free position" at least once to make sure of proper position. From the "free position" tighten adjusting nut 2 to 3 notches to preload the bearings, then tighten all four cap bolts to 100-120 ft. lbs. Mount a dial indicator to bear against a ring gear tooth so that contact can be made near heel end of tooth. Check gear backlash. On a new gear set, the lash should not be less than .006" nor more than .011", with .007-.009" preferred. If original gear set is being installed, the original gear backlash should be maintained. If backlash is not within limits, move ring gear to right or left as required to secure proper backlash. To move ring gear, loosen all four bearing cap bolts ¼ turn, loosen one notch on bearing adjuster on side toward which gear is to be moved and tighten one notch on opposite side. *(CAUTION*—When one adjuster is loosened, always tighten opposite adjuster the same amount in order to maintain the bearing preload adjustment). One notch change of both adjusters in the same direction will result in changing gear lash approximately .0035". Always tighten all bearing caps to 100-120 ft. lbs. after adjusters have been moved and recheck lash with dial indicator. When lash is properly set, install both bearing adjuster locks. Install differential side gears and thrust washers in case, lubricate bearings and install axle shafts.

Pinion Setting (Using J-681-A & J-2197 Pinion Setting Gauges): *Se 1951 or Later Manual editions.*

Pinion Setting (Using J-5647 Gauge): This pinion setting gauge consists of a "master gauge" and an "indicator gauge" upon which Dial Indicator KMO-5647 is mounted. Make certain that gauge parts are clean, particularly the center and discs on indicator gauge and the centering holes, indicator pads and the disc pads on the master gauge. Install the small contact button on stem of dial indicator and mount dial indicator on indicator gauge of tool. Place the indicator gauge on master gauge so that spring loaded center is engaged in centering hole corresponding to the indicator pad "B" (which is used for any of the following gear ratios stamped on pinion 43-11, 43-12, 41-12, 42-13. *NOTE—Pad "A" is used for certain previous models.* Center the indicator contact button on specified indicator contact button on specified indicator pad and lock indicator by tightening lock screw. Hold yoke down firmly, with both discs contacting the horizontal and vertical pads on master gauge, and set dial indicator at "zero". Place transmission in "neutral" Make certain that differential bearing seats in carrier are clean and free of burrs, and that center in pinion is also clean. Rotate pinion until blank tooth between the matching numbers and the pinion setting mark is slightly counterclockwise of top center (at 11 o'clock). This tooth is called the gauging tooth (used for locating and gauging during production) and should be used for gauging Place indicator gauge in carrier with discs seated in bearing seats (clear of threads and inner edges), with gauge center engaged in center of pinion, and with contact button having good contact on gauging tooth of pinion. Press gauge yoke firmly inward toward pinion and read dial indicator noting whether it is plus (+) or minus (-), as indicated by arrows on surface of yoke. Recheck indicator zero setting on master gauge to make sure it was not changed in handling. If the old ring and pinion gear set is being reinstalled and it had been in use long enough to establish a wear pattern on teeth, the original setting found at time of removal should be maintained. If the ring gear and pinion set is new or has not been in use long enough to establish a wear pattern on teeth, the dial indicator reading should be within .001' of pinion setting marked on pinion.

Pinion Adjustment· Remove pinion and propeller shaft assembly and remove all pinion bearing shims from shaft or from carrier housing. Wipe shims dry, and measure the total thickness with a micrometer. Increase or decrease total thickness of shims to obtain proper pinion setting, by using a different combination of shims *(NOTE*—These shims are furnished in thickness ranging from .010' to .019' in increments in .001'). As an example, if pinion is marked + 8, but dial indicator reads +6, decrease total thickness of shims by 002' (if the above marking and dial reading were "minus", shims would be increased in thickness). If dial reading were to read +10 for the above marked pinion, increase total thickness of shims by .002". Install pinion and propeller shaft assembly with a new combination of shims and be sure to tighten the three bearing sleeve locks uniformly to 35-40 ft. lbs., and lock nuts to 15-20 ft. lbs. Check pinion setting with gauge. Setting must be within .001" of setting marked on pinion.

1946-55 CADILLAC HYPOID

Cadillac V8 (1946-55)

►1949-55 **AXLE SHAFT NOTE:** Shafts on all series, except Commercial Chassis are integral flanged type.

►CHANGES, CAUTIONS, CORRECTIONS

►**REAR AXLE SERVICE CAUTION—Manufacturer recommends that all service on the Differential Carrier Assembly other than oil seal or universal joint yoke replacement (and necessary pinion bearing pre-load adjustment) be handled by replacement of the complete assembly.** ***No disassembly or adjustment of this unit should be attempted in the field.***

►**REAR AXLE IDENTIFICATION MARK:** Gear ratio of axles is indicated by marking stamped on bottom of differential case beneath center of pinion shaft. See Car Model pages for ratios and markings.

►**PINION BEARING ADJUSTMENT CAUTION: Pinion bearing adjustment (pre-load) controlled by rear universal yoke nut which compresses spacer or sleeve between pinion bearings.**

►***CAUTION*—Loosening or removal of the pinion shaft nut (for oil seal or yoke replacement) will disturb pinion bearing pre-load and exact procedure detailed below must be followed to avoid overloading bearings or collapsing bearing spacer.**

DESCRIPTION: Hypoid gear with Hotchkiss drive. Differential housing is barrel type with provision made to remove and install pinions and side gears through right hand end (case closed by end cap screwed in housing and retained by locking screw or taper locking pin installed from outside of case. Differential assembly mounted on taper roller bearings (bearing cups seated in ends of differential housing) with threaded sleeve type adjusting nut at outer end of each bearing. Adjusting sleeves are locked by clamp bolt in each bearing post. Several types of pinion mountings used as follows:

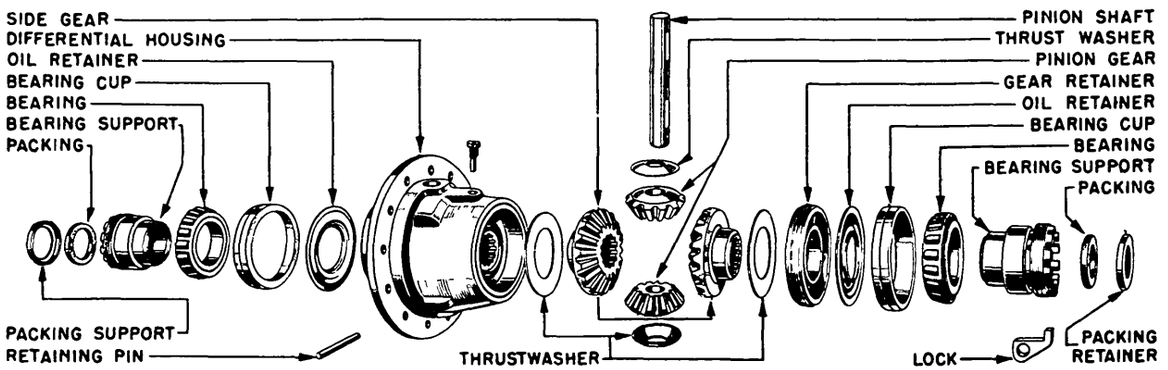
REMOVAL OF AXLE: ***See Rear Axle on car model page.***

PINION OIL SEAL OR UNIVERSAL YOKE REPLACEMENT:

►***CAUTION—Pinion bearing pre-load (turning torque) must be measured before pinion shaft nut loosened.***

Pinion Bearing Pre-load Measurement: With rear wheels and brake drums removed and propeller shaft disconnected at rear universal, drain axle lubricant, measure inch-pounds torque required to turn pinion shaft using a 50-inch pound torque wrench with special socket J-2571-1 and Adapter J-2571-2 on pinion shaft nut. Before taking a torque wrench reading, rotate pinion shaft ¼ turn in each direction (to free pinion and overcome initial high starting torque), then note torque reading while rotating shaft at least ½ turn and record this torque reading. Repeat above check at least eight times to insure accurate check over entire circumference of ring gear, calculate the average of all torque readings for use when retightening nut.

Removal of Yoke & Oil Seal: Mark yoke and pinion shaft with a punch for re-installation of yoke in same position on shaft. Install Yoke Holding Tool J-2659, insert special socket J-2571-1 through hole in holding tool, use ¾" drive wrench to remove pinion nut. Drive yoke off pinion shaft splines (1946-52); use puller J-5514 (later). Use Seal Remover J-2623 to remove oil seal. Remove staking burrs from pinion shaft with small file or ⅞"x14 thread die (CAUTION—Protect bearings from chips by wrapping cloth around shaft). Try new pinion nut for free turning.



Installation of Oil Seal: Coat outer edge of seal and retainer with good sealer, use Oil Seal Installer Tool J-1357 to drive seal into carrier. Install yoke (CAUTION—line up marks made before disassembly), install new pinion nut. Hold yoke with tool J-2659. tighten pinion nut to 225 ft. lbs., measure and adjust bearing pre-load or turning torque as follows:

Pinion Bearing Pre-load Adjustment: After pinion nut tightened to 225 ft. lbs. (above), measure pinion **bearing pre-load in exactly the same manner as followed before pinion nut loosened (see directions above). Average turning torque (for all readings) at this time should be 5 inch-pounds ±2 lbs. greater than average turning torque recorded before nut loosened. If turning torque too low, tighten nut approximately 30° (⅓ one flat), and again measure turning torque. Repeat this procedure until correct torque obtained, then stake pinion shaft into nut.**

►***CAUTION—Do not overtighten pinion nut and never back off nut to reduce the pre-load.***

Pinion Bearing Pre-load·
(Pinion shaft Turning Torque)

New Assembly	50 in. lbs. max.
After 1000 miles (used Oil Seal)	15 in. lbs. max.
After 1000 miles (new Oil Seal)	20 in. lbs. max.

CADILLAC REAR AXLE ASSEMBLY

AXLE SHAFT REPLACEMENT: 1949-55 Axle Shaft is new "flanged" type which does not have separate wheel hub (brake drum and wheel bolted directly to shaft flange). Install new oil seal whenever seal removed.

1946-48 Axle Shaft Removal & Installation—Use puller such as S-4567 five-jaw type to remove wheel hub and brake drum assembly, disconnect brake line, remove dust shield (backing plate assembly) by taking off nuts on mounting bolts. Use puller J-838 to remove axle shaft and bearing using great care not to damage oil seal.

Wheel Bearing Replacement—When replacing axle shaft oil seal, inspect wheel bearing for loss of lubricant (bearings are "sealed type" and lubricant may have been washed out by axle lubricant leaking past oil seal). If wheel bearing spins freely (indicating lack of lubricant), replace bearing.

1949-55 Axle Shaft Removal & Installation—With wheel off, take out retaining screws and remove brake drum. Remove nuts and lockwashers mounting bearing retainer and backing plate on rear axle housing. Use puller J-942-1 (with slide hammer tool J-2619) to remove axle shaft using great care not to damage oil seal or disturb position of backing plate.

Wheel Bearing Replacement—Bearings are sealed type and should be inspected for loss of lubricant. A bearing that spins freely should be replaced.

Bearing Removal & Installation—Use cold chisel and hammer to nick spacer next to bearing (not necessary to split spacer), slip spacer off shaft. Use special Bearing Remover & Replacer Tool J-2986 (place "U" shaped part of tool under bearing, place square part of tool around bearing to prevent it exploding), press bearing off shaft in arbor press. Install new bearing on shaft with same tool, pressing bearing on until it not quite touches shoulder on shaft, then press new spacer on shaft against bearing.

Axle Shaft Oil Seal Replacement—Make certain that all nicks and burrs removed from counterbore into which seal fits, polish shaft on which seal leather bears. Dip new seals in clean engine oil, coat inner surface of oil seal leather with chassis lubricant, coat outer suface of oil seal metal shell with sealer compound. Use tool J-1355A (axles with separate wheel hub), J-3069 (axles with flanged shaft without wheel hub) to install seal in housing.

DIFFERENTIAL CARRIER ASSEMBLY OVERHAUL: Manufacturer recommends that all services other than oil seal or universal joint yoke replacement (above) should be handled by replacement of the assembly. No attempt should be made to disassemble or adjust the carrier assembly in the field.

Carrier Assembly Installation—When installing carrier, tighten capscrews to 30-35 ft. lbs. If oil leaks noted between carrier flange and housing, correct by installing extra gasket at this point with sealing compound on gaskets. **Do not tighten capscrews excessively to correct oil leaks.**

Checking Backlash—Raise car on hoist and fasten one end of piece of bar stock to yoke on pinion shaft and the other end to frame side rail by means of "C" clamps to prevent rotation of drive shaft. Apply emergency brake cable on one wheel to hold wheel stationary, and measure backlash in inches at outer circumference of tire tread. A stiff wire pointer fastened to fender of car will aid in this measurement. Maximum backlash at wheel should not exceed ½".

1946-54 CHEVROLET HYPOID (SEMI-FLOATING)

Passenger Cars (1946-54)
Half-Ton Trucks (1946-54)

▷CHANGES, CAUTIONS, CORRECTIONS

▷*PROPELLER SHAFT COUPLING FIT PRODUCTION CHANGE—See "Overhaul" below.*

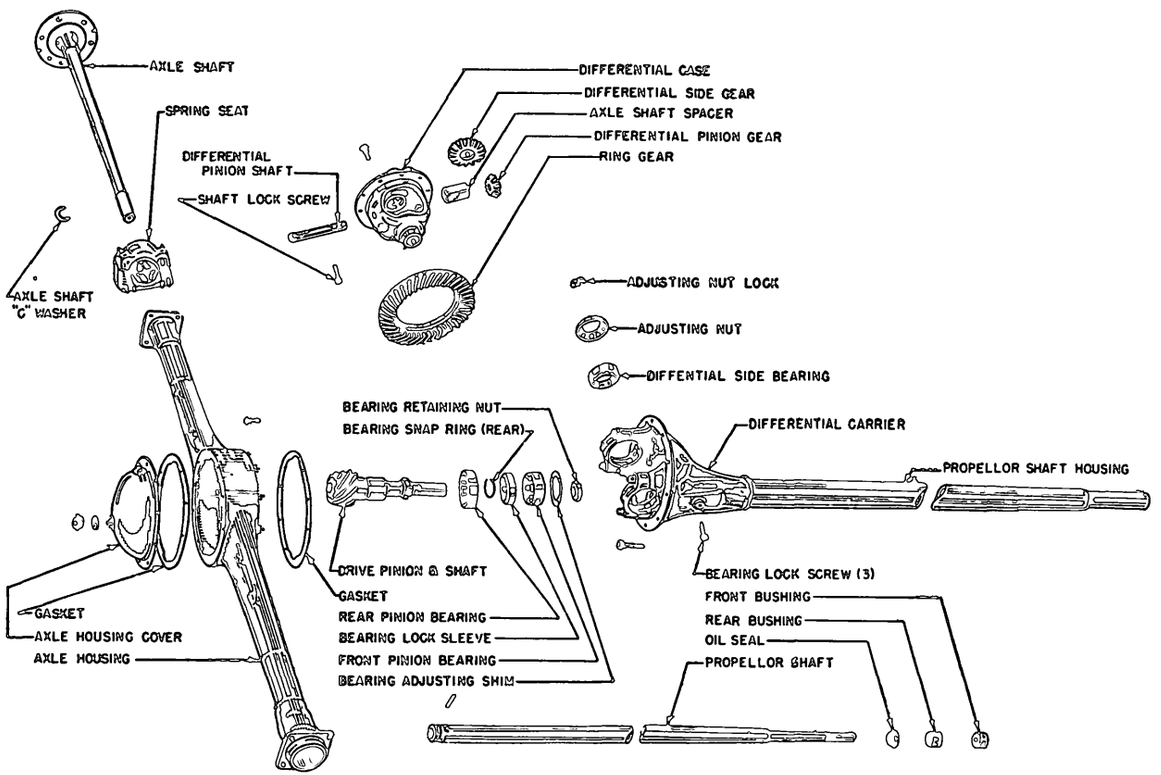
▷*1952 PINION BEARING PRODUCTION CHANGE*—A new "W" type double row bearing, New Departure No. ND 5306W, replaces Pinion Bearing, Chev. No. 954394 and 954533. When installing "W" type bearings, the bearing loading slot must be installed toward pinion.

▷PINION BEARING LOCK SLEEVE LOCKSCREW INSTALLATION CAUTION: Both sleeve face and tapered end of Lockscrew should be coated with Rear Axle Lubricant when these parts installed to prevent screw cutting or scoring face of sleeve when screws are tightened. CAUTION—If these parts not lubricated, and screw cuts face of lock sleeve, screw may bottom without forcing sleeve into position against bearing which may cause failure of pinion bearings or ring and pinion gear due to incorrect adjustment.

▷REVACYCLE DIFFERENTIAL PIN & SIDE GEARS (Not used on Half-Ton Truck Models)—Revacycle gears must be used together and must not be interchanged singly with other type gears.

▷INSTALLATION OF 1950 TYPE TORQUE TUBE BUSHINGS (Propeller shaft front bearing) on Previous Models: New press-fit type bushings (not pinned may be installed in 1940-50 Passenger Cars and 1939-50 Half-Ton but must be tight fit (if fit doubtful, pin should be installed). *See Propeller Shaft & Front Bearing data below.*

▷UNIVERSAL JOINT & PROPELLER SHAFT BUSHING LUBRICATION CAUTION (Powerglide Cars): These parts lubricated from Powerglide transmission output shaft through oil passage in special drilled universal joint retaining bolt No. 3690869 (bolt drilled completely through and has special flat head nail inserted in hole to keep oil passage open). If universal joint or bushing lubrication troubles experienced, make certain that drilled bolt used and that nail is free in oil passage (1/32-1/16" clearance between head of nail and head of bolt).



▷*CAUTION—Plain bolt used for transmission run-in at factory must be replaced by this special drilled bolt when transmission installed in car.*

▷AXLE IDENTIFICATION & RATIO NOTE—See Chevrolet Car Model pages for axle ratios and identification.

DESCRIPTION: Hypoid gear, semi-floating type with torque tube drive.

REMOVAL OF AXLE: *See "Rear Axle" on car model page.*

AXLE SHAFT REPLACEMENT: Check endplay when installing axle shafts (see below).

CHEVROLET HYPOID SEMI-FLOATING AXLE

Axle Shaft Removal—Remove wheels, take out both 'zipon' nuts mounting brake drum to axle shaft flange and remove drum. Remove axle housing rear cover, take out pinion shaft screw, withdraw pinion shaft, lift out axle spacer block. Push shafts in toward center of housing, remove "C" washers at inner ends within differential side gears, withdraw axle shafts. When replacing shafts, check endplay.

Axle Shaft Note—Axle shafts are of unequal length. *See Chevrolet Special Data in car model section for shaft part numbers and identification marks.*

CAUTION—Install longer axle shaft on right side.

New Axle Shaft Installation. Wheel hub bolts are press fit in axle flange and must be installed in new shafts (these bolts hold oil deflector assembly on flange). Coat new gasket with heavy shellac or paint, install gasket and oil deflector on flange lining up oil holes (extra center hole of three closest together should be lined up with notch in flange, oil pocket in deflector should also line up with this notch), insert special wheel bolts and force heads down to deflector, peen shoulder on bolts into countersink around bolt holes in flange (this is very important). Check shaft endplay.

Axle Shaft Endplay (Passenger Cars)—Controlled by spacer assembled on differential pinion shaft between inner ends of axle shafts. Endplay should be from a free fit to .014" maximum. Select correct spacer block (see data below) to give this endplay. Install spacer block with ground faces of block toward axle shaft ends. NOTE—Medium spacer block ground on all four sides and may be installed either way to secure either of these two sizes.

Part No.	Pass. Car Spacer Blocks	Size
597251		Narrow (1.012")
473603		(1.0195" & 1.0295")
597254①		Wide (1.0345")

Axle Shaft Endplay (Trucks)—Same as for Passenger Car (above) except that spacer blocks furnished in two types for three sizes as listed below (wide block ground on all four sides, may be installed either way).

Part No.	Truck Spacer Blocks	Size
370217		Narrow (1.1485")
372515		Wide (1.1575" & 1.1675")

Axle Bearing & Oil Seal Installation—Before installing new parts, make certain that axle housing is clean and smooth (remove old staking marks), coat outer diameter of seal retainer lightly with Permatex (use care not to get Permatex on seal). Assemble bearing, retainer, and oil seal on end of driver, seat parts in place in housing with few light blows of a hammer on the driver. Remove tool, stake oil seal in place with a prick punch. NOTE—Spring-loaded type seals are not staked.

PROPELLER SHAFT & FRONT BEARING: Propeller shaft is part of pinion and shaft assembly (see "Overhaul" data following).

Propeller Shaft Bushings: *CAUTION—Both "doweled" type and "press fit" bushings have been used as follows:*

"Doweled" Bushings (Early 1950 & Previous Models)—Doweled type replacement bushings (see listing below) must be used on these models where doweled bushings used originally to prevent possibility of interference between torque tube and torque ball sleeve (tube may be expanded by installation of bushing). *These bushings removed and installed in same manner as on previous models.*

"Press Fit" Bushings (1950-54 Models)—These

CONTINUED ON NEXT PAGE

1946-54 CHEVROLET HYPOID SEMI-FLOATING (Continued)

bushings used in production and torque tube finish-ground after installation to prevent possibility of interference mentioned above. Use press fit type replacement bushings (see listing below) for these models and remove and install these bushings as follows:

"Press Fit" Bushing Removal & Installation—Use special Puller J-4258 (see note for 1951 models below) to remove both bushings and oil seal from torque tube. Install new parts in following order: Oil Seal (use Driver J-968, placing seal on driver with free side of leather toward head of driver), Rear Bushing (use Driver J-4259 with spacer washer on driver), Front Bushing (use Driver J-4290). Drive bushings in until stop on driver is against end of torque tube. Drivers will position bushings correctly.

►*CAUTION—If new bushings are not tight fit in old torque tube, bushings should be drilled and dowel pins installed (see "Dowel Pinned" bearing data).*

►**Bushing Puller J-4258 Note**—This tool designed originally for 1950 type pressed bushings and interference will be noted if used in later bushings (bushings have larger O.D. for use in new larger-diameater and thinner-wall torque tube) unless sleeve diameter of tool increased .040" (increase I.D. of sleeve from 1.750" to 1.795" ± .005"). New tools will have this increased sleeve diameter.

Replacement Torque Tube Bushings

Car Model	Front No.	Rear No.
"Doweled" Type		
1946-50 Pass. Cars	3652601	3652328
1946-50 Half-Ton	595007	②3652328
"Press Fit" Type		
1950 Pass. Cars	3691484	3691475
1950 Half-Ton	3691490	3691475
1951-54 Pass. Cars	3694732	3694733
1951-54 Half-Ton	3694761	3694733

②—Except 1947 No. 3686064.

►**Oil Seal on Powerglide Cars**—Special rubber-encased seal used to prevent oil leaks around outer diameter of seal retainer. This seal is Part No. 3691457 and is used in this 3.55-1 Ratio axle only.

OVERHAUL: Disassembly—Drain lubricant and remove rear housing cover. Remove axle shafts (see data above). Remove nuts retaining torque tube on axle housing, remove torque tube, propeller shaft and pinion assembly. Remove adjusting nut locks on differential side bearing caps, remove bearing cap screws. Remove bearing caps and adjusting nuts, lift differential assembly out. Dismantle and service sub-assemblies as follows:

►**1952 Pinion Bearing Production Change**—A new "W" type double row bearing, New Departure No. ND 5306W, replaces pinion bearing, Chev. No. 954394 and 954533. When installing "W" type bearings, the bearing loading slot must be installed toward pinion.

Pinion Bearing & Propeller Shaft Assembly: To remove from torque tube, loosen locknuts and take out retaining screws on side of housing, withdraw assembly from torque tube. To dismantle assembly, drill out head of rivet pin in propeller shaft, loosen pinion bearing locknut, disassemble pinion from propeller shaft. Use J-996 pinion bearing remover to press double row ball bearing from pinion shaft. remove locking sleeve or bearing retaining collar, remove lock ring from pinion shaft, take off roller bearing. Front double row ball bearing must have no perceptible endplay (new bearings may be .001" tight or have some drag). Assemble in reverse order making certain that lock ring installed on shaft ahead of roller bearing (to prevent rollers creeping) and that locking sleeve installed with beveled edge towards pinion. Tighten bearing locknut to 200-240 ft. lbs., stake nut in shaft slot. Use new rivet pin when assembling pinion and propeller shaft and rivet both ends of pin securely. Make certain that pinion setting shims installed in housing (see Pinion Setting below), insert propeller shaft assembly with spacer J-4050 between pinion and roller bearing to maintain proper pinion-to-bearing clearance, drive assembly down to seat bearings properly (use drift in hole in end of pinion, do not drive on end of pinion teeth). Make certain that locking sleeve down against front bearing, install the three tapered lockscrews, tighten these screws evenly and securely, tighten locknuts.

►*CAUTION*—Coat beveled face of pinion bearing lock sleeve and tapered ends of lockscrews with rear axle lubricant before installing to prevent screws cutting or scoring sleeve which would cause incorrect axle adjustment and early failure of bearings and gears.

Pinion Bearing Assembly Note (½ Ton 1941 & Later). To install pinion bearings on shaft, install rear roller bearing and lock ring, then thread pinion front bearing oil retainer on shaft with bevel of large diameter of retainer toward pinion, assemble bearing lock sleeve with bevel side toward pinion, install front double row ball bearing and bearing retainer nut. All other assembly and adjustment instructions same as for passenger car models.

Pinion Setting:—Pinion position controlled by shims installed in housing ahead of front bearing. Standard assembly .033" shim thickness (one .015" shim, one .018" shim) and should be used for new gears. Shim pack can be varied from .024" to .042" and shims are furnished as follows:

Part No.	Pinion Setting Shims Thickness
3657740	.012"
3657741	.015"
3657742	.018"
3657743	.021"

Differential Bearing Assembly:—Use special puller to remove bearings from differential case hubs (notches provided in case for puller so that pressure applied to inner races only). Use J-994 bearing replacer to install bearings. When installing differential assembly in carrier (third member), make certain that marks on bearing caps and carrier line up

Differential Bearing Adjustment:—With carrier or third member assembly out of axle housing, tighten differential bearing cap screws until lockwashers are just flattened, turn right hand adjusting nut up until it is just snug, then turn nut additional 1-2 notches to locking position, tighten bearing cap screws evenly to 65-80 ft. lbs. (Pass. Cars), 115-135 ft. lbs. (Half-Ton), install adjusting nut locks.

Ring Gear Backlash Adjustment. To set up differential assembly for correct backlash when installing assembly in carrier, turn left hand adjusting nut in slowly until all backlash between ring gear and pinion taken up (revolve ring gear while making this adjustment), then back adjusting nut off one notch. Adjust differential bearings by turning right hand adjusting nut as directed above. This setting should give correct backlash of .005-.007". After bearing adjustment completed, recheck backlash and if not correct, adjust by backing off one adjusting nut and tightening opposite nut exactly the same amount to avoid disturbing bearing adjustment.

Ring Gear Replacement:—Run-out of differential case flange must not exceed .001" with ring gear removed. When installing ring gear, use guide pins in alternate bolt holes to position gear while bolts are being installed, use new lockwashers under bolt heads, tighten all bolts evenly to 40-60 ft. lbs. (Pass. Cars), 85-95 ft. lbs. (Half-Ton). Check ring gear run-out which should not exceed .0035" (measured on back face of gear).

1955 CHEVROLET HYPOID (HOTCHKISS DRIVE)

Ch vr l t Pass. Cars & S d. Del. (1955)
Ch vr l t ½-T on Trucks (1955)

DESCRIPTION: Semi-floating, hypoid gear type with hotchkiss drive. The drive pinion is mounted on preloaded tapered roller bearings.

►*PINION BEARING PRELOAD CAUTION:* Pinion bearing preload must be adjusted whenever universal flange nut on pinion shaft loosened (preload controlled by this nut and will be disturbed when nut loosened).

REAR AXLE ASSEMBLY REMOVAL: *See "Rear Axle" on Car Mod l pages.*

AXLE SHAFT REPLACEMENT: Removal–Raise rear of car and place jack stands under rear axle housing. Remove hub nuts and remove tire and wheel. Remove brake drum and gasket. Remove nuts and lockwashers from bearing retaining bolts on inside of axle flange. Attach axle puller J-5748 with slide hammer to hub nuts and remove axle and bearing assembly, being careful not to disturb backing plate (*NOTE*–If bearing retainer and parking brake strut interefere, raise strut slightly for clearance). Install bolt and nut to hold backing plate on axle housing.

B aring or Oil Seal R placement–Using a hammer and chisel, nick the soft ring next to bearing and remove ring (*NOTE*–It is not necessary to split the ring completely for removal). Install press plate J-5741 between axle flange and bearing with the land of the plates against bearing and inside the retainer. Install bolts in plates. Press bearing from shaft with press plate parting line resting on press bed (*CAUTION–Press plates must be supported at parting line).* To replace seal, pry out old seal being careful not to damage bearing races. Install new seal using guide tool J-5747. Tap seal in place with a plastic hammer. Install new bearing or resealed old bearing with installer tool J-5746 so bearing seats on shaft against shoulder. (*CAUTION*–Bearing retainer must be on shaft before bearing installed). Install new axle shaft bearing retaining ring on shaft with tool J-5746 to seat ring against bearing (chamfered side of ring must be against bearing).

►*AXLE SHAFT REPLACEMENT NOTE:* If a new shaft is being installed, insert the five new special bolts and force heads down to flange on axle. Peen end of shoulder on bolts into countersink around holes in flange using tool J-554. Install new bearing (see above).

Installation: Replace bearing "O" ring seal. Remove temporary nut and bolt holding brake backing plate in place. Install new retainer gasket and install axle shaft in housing using axle shaft tool J-5748 and slide hammer. Rotate shaft to align splines of shaft and differential side gear. Outer race of bearing must seat against shoulder in axle housing. Install nuts and lockwashers on bearing retainer bolts and tighten securely. Install brake drum gasket, drum, wheel and hub nuts.

COMPANION FLANGE, OIL DEFLECTOR OR SEAL REPLACEMENT: Removal–Raise one rear wheel off floor with jack stand placed under frame side rail. *(NOTE–This is to lock one rear wheel and obtain differential to body clearance. If operation is to be performed on a hoist, support frame on jack stands, allow axle to drop for clearance and expand brake shoes on one wheel to lock it securely).*

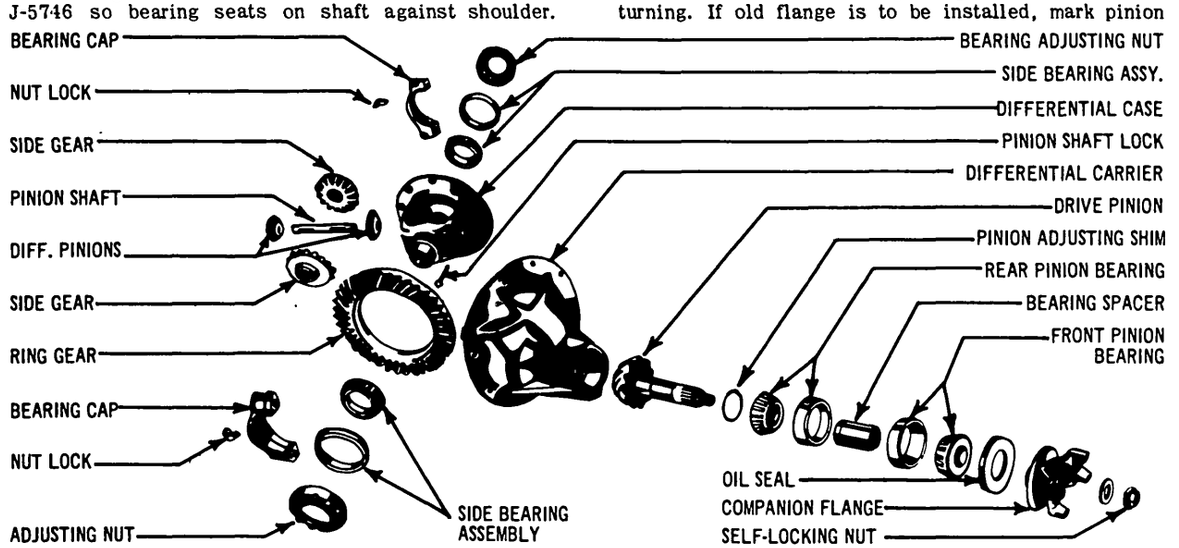
1) Check free wheel for freedom of rotation. Separate rear universal joint, tape trunnion bearings to joint and drop propeller shaft to floor.

2) Using an inch-pound torque wrench on the companion flange nut, rotate pinion through several complete revolutions and record the torque required to keep pinion and flange for reassembly in the same relative position.

3) Hold drive flange using tool J-2637-A, remove companion flange nut and special washer. Discard nut and use a new one at reassembly. Remove drive flange using tool J-820-A bolted over holding tool J-2637-A. Pry oil seal out using a screwdriver or hammer and chisel. Inspect drive flange for smooth oil seal surface or worn drive splines. On new flanges or old flanges with damaged deflectors, install new deflector, using tool J-5749.

4) Soak new seal in light engine oil for 10 minutes before installation. Wipe outer diameter of seal and then coat outer diameter with Permatex No. 3 or similar sealer. Install seal using tool J-5154.

5) Install drive flange, aligning marks on pinion and flange if old flange is being used. If flange does not go on shaft easily, use tool J-5780 to pull it on.



►*CAUTION: Do not hammer flange on pinion shaft as damage to ring gear and pinion will result.*

6) Install washer and a new self-locking nut. Tighten nut to remove endplay and continue alternately tightening in small increments and checking preload torque with inch-pound torque wrench until it is the same as recorded at disassembly. Readjust brake if it was expanded to hold wheel.

DIFFERENTIAL CARRIER: Removal–Clean dirt from area around carrier and housing joint and remove axle shafts (see above), pulling them out only far enough to clear carrier. Disconnect rear universal joint and lower propeller shaft to floor. Remove nuts and copper washers attaching carrier to rear axle housing. Place a drip pan under carrier and slightly separate carrier and housing and allow lubricant to drain out. Remove differential carrier assembly.

Disassembly: Mount carrier assembly in a vise or fixture J-3289. Mark caps and carrier for reassembly in same position. Remove differential adjusting nut locks and bearing cap bolts. Remove bearing caps and adjusting nuts by tapping on bosses of caps until free from dowels. (*CAUTION*–Do not pry caps off as this may damage machined face of cap). Remove differential and ring gear assembly from carrier housing being careful not to drop side bearing outer races. Remove differential pinion shaft screw and lockwasher and differential pinion shaft from case, and remove pinions and side gears. Hold companion flange from turning with tool J-2637-A and remove propeller shaft pinion flange nut and washer. Remove flange with tool J-820-A, bolted to flange with holding tool in place. Remove pinion from carrier by tapping on front end with soft hammer. Remove pinion shaft oil seal, pinion front bearing and bearing spacer from carrier. (*NOTE*–Some axles may have a 1/16" shim located behind spacer. This is a production item only and should be discarded).

Inspection: Wash all parts in cleaning solvent and thoroughly clean axle housing. Inspect all bearing cups, cones and rollers for chipping or evidence of excessive wear. On pinion bearing rollers, inspect large end of rollers for wear (*NOTE*–The pinion bearings are preloaded, and the natural wear pattern is a frosted condition with occasional slight scratches on races

CHEVR LET HYP ID REAR AXLE (HOTCHKISS DRIVE)

CONTINUED ON NEXT PAGE

1955 CHEVROLET HYPOID (HOTCHKISS DRIVE) (Cont.)

or rollers. This does not indicate a defective bearing). Inspect oil seal for wear or damage and pinion shaft splines and flange for excessive wear. Inspect ring gear and pinion teeth for scoring, cracking or chipping and differential case for cracks or scores on side gear and pinion thrust faces. Check fit of differential side gears in case and fit on axle shaft splines. Inspect differential pinion shaft for scoring or evidence of excessive wear. Inspect carrier for cracks or crossed threads on bearing caps and bosses.

Drive Pinion Bearing Replacement: Remove front and rear bearing outer races from carrier with a brass drift. Install new bearing cups in carrier using tool J-270-6 on front cup and J-270-14 on rear cup, driving bearing races in until they seat against shoulders in housing. Remove rear pinion bearing inner cone and roller assembly using tool J-5740 press plate, in an arbor press *(CAUTION–Note size of shim removed from between cone and gear).* If original ring gear and pinion are being reinstalled in the original carrier, install the original shim pack. If a new ring gear and pinion, or a new carrier is being installed, *see "Pinion Gear Setting" below.*

Pinion Gear Setting: When installing a new pinion gear or differential carrier, determine the correct amount of shims to install between pinion gear and bearing by checking the markings on end of pinion gear and on carrier flange face, and then referring to Pinion Shim Table below. Carrier is marked S-1, D-1 etc., and pinion gear is marked +1, -1 etc. As an example, a +1 pinion in a S-1 carrier should have a .030" shim.

Pinion Shim Table

Pinion Mark	Carrier Mark S-3	S-2	S-1	0	D-1	D-2	D-3
-5	.024"	.024"	.024"	.027"	.027"	.027"	.027"
-4	.024"	.024"	.024"	.027"	.027"	.027"	.030"
-3	.024"	.024"	.027"	.027"	.027"	.030"	.030"
-2	.024"	.027"	.027"	.027"	.030"	.030"	.030"
-1	.027"	.027"	.027"	.030"	.030"	.030"	.033"
0	.027"	.027"	.030"	.030"	.030"	.033"	.033"
+1	.027"	.030"	.030"	.030"	.033"	.033"	.033"
+2	.030"	.030"	.030"	.033"	.033"	.033"	.036"
+3	.030"	.030"	.033"	.033"	.033"	.036"	.036"
+4	.030"	.033"	.033"	.033"	.036"	.036"	.036"
+5	.033"	.033"	.033"	.036"	.036"	.036"	

Differential Bearing Replacement: Install differential bearing puller TR-278-R, making sure that puller legs are fitted securely and retaining yoke is tight. Tighten puller screw and remove bearing. Install a new bearing on hub with the thick side of inner race toward case and drive in place with tool J-5768 *(NOTE–*This tool is counterbored and has a pilot to assure proper installation and seating of bearing).

Ring Gear & Differential Case Replacement: Remove ring gear bolts and lockwashers and using a soft hammer, tap ring gear off the case. Install guide pins made from 3/8"-24x1½" long capscrews with heads cut off and ends slotted, in alternate bolt holes in ring gear. Make sure back face of ring gear and face of case are free of dirt and burrs. Mount case on "V" blocks placed at side bearings and check face runout with a dial indicator. This should not exceed .003". Drop ring gear over pilot diameter of the case, then install every other ring gear bolt and lockwasher and draw them up evenly and snugly so that ring gear face is flush with face of case. Remove guide pins and install remaining bolts. Tighten all bolts to 40-60 ft. lbs.

Differential Carrier Reassembly: Mount carrier in a vise or holding fixture. Lubricate pinion bearings with hypoid lubricant and install pinion in carrier. Install pinion bearing spacer with large end toward gear (use a new spacer). Install front pinion bearing cone and roller assembly on pinion shaft. Soak a new oil seal for 10 minutes in light engine oil. Wipe outer diameter of seal dry then coat outer diameter with Permatex No. 3. Install seal using J-5154. Install pinion flange and deflector assembly using tool J-5780 and J-2637-A. Install special washer and new self-locking nut. Tighten pinion flange nut, holding companion flange with tool J-2637-A. until torque required to keep pinion rotating is 15 to 25 inch pounds (this may require a nut torque of as much as 350 ft. lbs. A torque wrench or a scale may be used to determine preload. A scale should read 1 7/8 to 3 1/8 pounds when applied at an 8" radius. *(CAUTION–When checking turning torque, make sure that there is no contact between deflector and carrier).* Install differential assembly in carrier and install outer races and adjusting nuts *(CAUTION–Carefully slide adjusting nuts alongside bearing so that threads on nuts fit into threads in carrier).* Install bearing caps, aligning marks on cap with marks on carrier. Install and tighten capscrews snugly (these will be retightened after ring gear and pinion are adjusted). Lubricate hubs of differential side gears with hypoid lubricant and install them in differential case. Roll the two differential pinions into position and install pinion gear shaft and shaft lockscrew.

Ring Gear & Pinion Adjustment: Loosen right hand adjusting nut and tighten left hand adjusting nut using wrench J-972 while turning ring gear. Tighten left hand nut until all lash is removed, then back off the left hand nut one notch to a locking position. Tighten right hand nut to force left hand bearing firmly into contact with left adjusting nut. Then loosen the right hand nut and again tighten snugly against the bearing *(NOTE–Nut will be snug against b aring when rollers begin to move when contact is made).* Tighten right hand nut a minimum of **on additi nal notch,** to a **maximum of two notches further** to a locking position. Mount a dial indicator on carrier and check backlash between ring gear and pinion. Backlash should be .005-.008". Correct by moving each adjustment nut an equal amount in the same direction to retain preload and change backlash. Tighten bearing cap bolts to 70-75 ft. lbs. Recheck backlash and install both adjusting nut locks.

Differential Carrier Installati n: Clean out axle housing thoroughly and place new gasket over carrier mounting bolts. Assemble differential carrier assembly to axle housing, install new copper washers and nuts and tighten securely. Connect rear universal joint.

CHEVROLET TRUCK HYPOID FULL-FLOATING

¾ & 1 Ton Trucks, All Models (1946-55)
1½ Ton, C-O-E & School Bus (1946-55)②
2 Ton Truck, All Models (1946-54)
2 Ton Truck, Except Low Cab Forward (1955)①②

①—"Chevrolet Truck (Heavy Duty)" Rear Axle is Standard on Low Cab Forward Models and Optional on others.

②—"Chevrolet Truck 2-Speed" Rear Axle is Optional on 1½ and 2-Ton Trucks.

►CHANGES, CAUTIONS, CORRECTIONS

►*1954-55 2-TON TRUCK REAR AXLE HOUSING NOTE:* Two interchangeable housings used concurrently

►*1954-55 2-TON TRUCK REPLACEMENT PARTS CAUTION:* Because of heavier design, the parts are not interchangeable with corresponding previous models.

►*1952 & LATER 2-TON TRUCK DIFFERENTIAL ASSEMBLY:* "Revacycle" type side and pinion gears used. .060" thrust washers are used. These gears must not be interchanged with "Involute" type gears used on earlier models and on ½, ¾, 1, and 1½ ton trucks.

"Revacycle" Side Gear Identification—Gear has 29 splines and 18 teeth.

"Revacycle" Pinion Gear Identification—Gear has 10 gear teeth ("Involute" type has 11 teeth).

►*AXLE IDENTIFICATION MARKING:* Ratio indicated by axle serial number prefix stamped on housing. See "Rear Axle" on individual truck model pages.

►*BRAKE DRUM (¾ & 1 TON) NOTE:* Brake drum is held to hub with two slotted screws. A soft paper gasket is used between drum and hub.

►*1946-50 BRAKE DRUM (1½ & 2 TON) NOTE:* Brake drum is held to hub by hub bolts which must be pressed out of the hub or driven out with a hammer. Gasket between inside of brake drum and oil deflector should be coated with heavy shellac or paint on both sides to prevent oil leaking onto braking surface of drum. Small hole in gasket and channel in oil deflector must be lined up with relief hole in drum.

►*1951 & LATER BRAKE DRUM (1½ & 2 TON) NOTE:* Brake drum is held to hub by three slotted screws making it unnecessary to remove hub before removing drum. A soft paper gasket is used between drum and hub.

DESCRIPTION: Hypoid gear, full-floating type with Hotchkiss drive. Pinion shaft is straddle mounted, being supported at rear by a roller bearing and at front by a double row ball bearing (1½ & 2 Ton), double row roller bearing (¾ & 1 Ton).

1947 & Later Splined Axle Shaft (1½ & 2 Ton): This type axle shaft has involute splines on flange at outer end of shaft which engage similar splines in wheel hub (concealed by hub cap retained by five capscrews.

¾ & 1 Ton Pinion Bearing (Front)—Bearing consists of a double opposed taper roller bearing (separate roller and cone assemblies in a single bearing

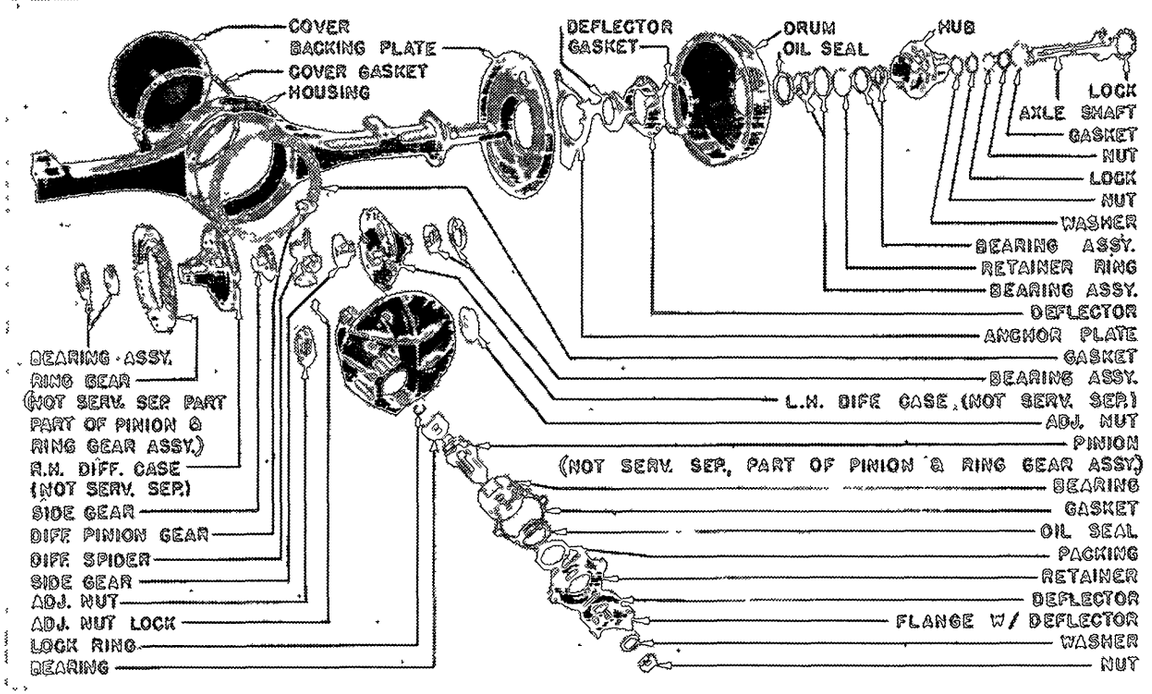
CONTINUED N NEXT PAGE

CHEVROLET TRUCK HYPOID FULL-FLOATING (Continued)

cup). A special spacer is used on the pinion shaft between the bearing cones. This spacer will provide correct bearing adjustment when the pinion shaft flange nut properly tightened (160-280 ft. lbs.).

CAUTION—Correct spacer must be used with each bearing assembly. This bearing is furnished as an assembly consisting of: One double outer race, two inner race and roller assemblies, one special spacer).

¾ & 1 Ton Pinion Setting Adjustment Shims—Pinion position controlled by shims in pinion bearing counterbore of carrier. Average shim pack is .033". Shims furnished .012", .015", .018", .021".



REMOVAL OF AXLE: *See "Rear Axle" on car model page.*

AXLE SHAFT REMOVAL & WHEEL BEARING ADJUSTMENT: Axle shafts can be removed and replaced without disturbing wheel bearings as follows:

Axle Shaft & Wheel Bearings (¾ & 1 Ton): To remove axle shaft, remove eight capscrews and lockwashers from axle shaft flange on wheel hub, install two ½"-13 capscrews in tapped holes in flange (between mounting screw holes), turn these screws up evenly to loosen axle shaft, withdraw shaft, discard old aluminum gasket. To install shaft, thoroughly clean axle shaft flange and end of wheel hub, use new aluminum gasket. Tighten all flange capscrews alternately and evenly to 85-95 ft. lbs.

NOTE—To correct complaints of leakage around flange bolts, coat bolt threads lightly with sealing compound. CAUTION— Keep sealer out of bearing.

Wheel Bearing Assembly (¾ & 1 Ton Trucks). To remove wheel bearings, remove axle shaft and wheel. Raise lip of adjusting nut lock, use wrench J-2222 to remove locknut, lock, inner adjusting nut, and lockwasher. Remove hub and drum assembly. Install clamp on wheel brake cylinder. Remove inner bearing and oil seal from hub with driver J-2232 (install driver, then press assembly out in an arbor press). To remove outer bearing, tap outer race away from snap ring, remove snap ring, press bearing from hub using bearing remover J-2230. Wash bearings in cleaning solvent, lubricate with engine oil and check for roughness, damaged rollers or retainers, cracked, chipped, or worn races. Pack the roller bearings with soft smooth cup grease. To install bearings, place inner race and roller assembly of outer bearing in wheel hub, install outer race with thin edge toward outer end of hub, press race into hub with replacer J-2223 until it clears snap ring groove, install snap ring, then press race back in positive contact with snap ring using J-2230 bearing remover inserted through bolt holes in outer end of hub. Install outer race of inner bearing in hub (wide edge of race inward) with replacer J-872-1 pressing race in against seat in hub. Install inner race and roller assembly, install oil seal using replacer J-2221. Lock seal in place by prick punching at three equally spaced points. Install wheel hub and drum (turn wheel to align bearing rollers), install thrustwasher and adjusting nut, adjust bearings, install lock and locknut.

CHEVROLET TRUCK HYPOID GEAR, FULL-FLOATING

Wheel Bearing Adjustment—Remove axle shafts (above), remove adjusting nut locknut and lock (within wheel hub), use special wrench J-2222, turn adjusting nut up tight, then back nut off ⅛ turn while rotating wheel by hand to see that it turns freely. Install lock and see that tangs line up with slots in adjusting nut, bend lock tang into slot in nut. Install and tighten outer locknut, bend lock tang into notch in nut. Replace axle shaft.

Axle Shaft & Wheel Bearings (1½ & 2 Ton Trucks with Bolted-on Type Axle Shaft): See ¾ & 1 Ton data (preceding).

Wheel Bearing Assembly & Adjustment—See 1½ and 2 Ton Splined Type Axle Shaft data below.

Axle Shaft & Wheel Bearings (1½ & 2 Ton Trucks with Splined Axle Shaft): Axle shaft flange has involute splines which engage similar splines in wheel hub. Shaft splines are tight fit (shaft removal requires use of puller) and shaft retained by hub cap (spacer in hub outside outer bearing race prevents shaft moving inward). To remove axle shaft, take out five screws, remove hub cap and gasket. Install special adapter J-1436-8 on regular J-1436 Rear Axle Shaft Bearing & Oil Seal Remover (remove puller jaws), thread adapter in hole in end of axle, pull axle shaft. Install axle shaft by indexing shaft and hub splines (may be necessary to move truck slightly to align splines in hub and differential side gears), tap shaft into place. Clean mating faces of hub and hub cap, use new gasket on hub cap, tighten hub cap screws securely.

Wheel Bearing Assembly—Removal—Remove axle shaft. Remove hub and drum assembly using special wrench J-870 (J-5670 on 1954 and later 2 Ton models) to remove adjusting nut and locknut. Remove inner bearing and oil seal with puller J-918-A (with spacer J-918-17 on 1954 and later 2 Ton models). Remove outer bearing, first tap outer race to relieve tension on snap ring, then remove snap ring from inside the hub. Remove bearings by driving on axle shaft spacer using an end cut off an old axle shaft. This will also bring out inner race and roller assembly. *(NOTE*—Care must be taken to engage edge of spacer and not damage bearing seat in housing. Race must also be driven out evenly).

Cleaning & Inspection—Wash bearings thoroughly in cleaning solvent. Inspect races for cracks, chips and wear. Inspect rollers and retainers for any damage. Lubricate bearings with engine oil and check them for roughness.

Installation—Pack bearing assemblies with soft smooth cup grease. To replace outer bearing, place axle shaft spacer and outer bearing (with thin edge of outer race downward) into wheel hub. Use bearing replacer J-872-1 (J-5698 on 1954 and later 2 Ton models) to press bearing into hub *(CAUTION* —Press race only far enough to install snap ring. This operation should be done in an arbor press). Install snap ring in groove on inside of hub. Using long ⅛" punch inserted through splines in hub drive on axle shaft spacer to force outer race into positive contact with snap ring. To replace inner bearing, place outer race of bearing in wheel hub with wide side of race down. Use driver J-872-4 (J-5669 on 1954 and later 2 Ton models) to press race against its seat. Install inner race and roller assembly. Press oil seal, coated with a light coat of Permatex, into place with oil seal replacer J-3067 (J-5669 on 1954 and later 2 Ton models). Stake oil seal in

CONTINUED ON NEXT PAGE

CHEVROLET TRUCK HYPOID FULL-FLOATING (C nt.)

place by prick punching at three equally spaced points on edge. Install wheel hub and drum assembly. Rotate assembly to line up bearings. Install thrust washer and adjusting nut.

Wheel Bearing Adjustment—Remove axle shafts (above). Using special wrench J-870 (J-5670 on 1954 and Later 2 Ton models) remove adjusting nut locknut and lock, then with same wrench, turn up adjusting nut until it is tight, then back off adjusting nut 45° (⅛ turn). Rotate the wheel by hand to see that it turns freely. Install adjusting nut lock and align nearest slot in nut with a tang on lock and bend tang into slot in nut. Install locknut and tighten securely, then lock into position by bending a tang of the lock into a slot in the locknut. Install axle shaft.

REAR AXLE OVERHAUL: Disassembly & Reassembly (All Truck)—Take out the mounting capscrews and remove differential carrier assembly from axle housing, loosen thrust pad locknut and remove ring gear thrust pad. Remove adjusting nut locks, bearing cap bolts and lockwashers. Remove bearing caps by tapping on cap bosses to free caps from locating dowels (CAUTION—do not pry on cap which may damage machined face), remove adjusting nuts. Lift differential and ring gear assembly from carrier. Remove bolts attaching pinion bearing retainer on carrier, remove pinion and shaft assembly from carrier (if necessary, use brass drift against pilot end of pinion shaft to drive assembly out of housing). On ¾ and 1 Ton Axle, remove shims from inside of carrier housing and note number and thickness of these shims (shims control pinion setting and must be replaced when axle reassembled). Overhaul axle sub-assemblies as follows:

Pinion Bearing Assembly (All 1½ & 2 Ton Trucks): Remove nut on end of pinion shaft, remove universal joint and bearing retainer and oil seal from shaft. To remove rear pinion bearing, remove lock ring, use special press plate J-1453 to press shaft and pinion out of bearing (CAUTION—make certain that raised portion of plate against bearing inner race to avoid damage to bearing). Use special pinion bearing remover J-1439 (6 tooth pinion), J-1440 (7 tooth pinion) installed over pinion so that it engages inner race of double row ball bearing, press shaft and pinion out of bearing. Wash all parts in gasoline, inspect for wear or damage. To reassemble, press front double row ball bearing on shaft making certain that extended portion of bearing inner race is toward gear teeth (CAUTION—If bearing not installed in this manner, rapid wear and gear failure will result). Press rear bearing on end of shaft with chamfered side of inner race toward pinion and install lock ring. Install pinion bearing retainer and oil seal on hub of universal joint flange, install assembly on pinion shaft, install washer and nut on shaft, tighten nut to 160-280 ft. lbs., install cotter pin.

Bearing Retainer Oil Seal—If oil seal being replaced, soak new seal in light engine oil for one hour, install felt packing in bottom on seal recess, then install seal with open end of leather toward pinion bearing and press seal down against felt packing using J-2231 Oil Seal Replacer.

Pinion Bearing Assembly (¾ & 1 Ton Trucks): Remove cotter pin, nut, and washer from end of pinion shaft, remove universal joint flange, bearing retainer and oil seal. Remove rear bearing snap ring, press bearing off shaft using J-2229 press plate. Install pinion bearing remover J-2224 (¾ Ton truck), J-2225 (1 Ton Truck) over pinion teeth, press front bearing off shaft. Wash all parts in cleaning solvent, examine bearing rollers and races for cracks, chips, and wear.

►*CAUTION*—Spacer installed on shaft between bearing inner races must be kept with bearing and reinstalled if bearing re-used (special spacer furnished with each bearing is designed to provide correct bearing pre-load when pinion shaft flange nut is properly tightened. This spacer furnished as part of pinion bearing assembly (assembly consists of: One Double Outer Race, Two Inner Race & Roller Assemblies, One Spacer).

To reassemble the bearings on the pinion shaft, press one inner race and roller assembly on shaft until it seats against pinion, install spacer on shaft, lubricate bearing rollers with engine oil, install outer race, press front inner race and roller assembly on shaft. Lubricate rear roller bearing, press bearing in place on end of pinion shaft using driver part of J-769 lock ring installer, install lock ring (thread ring on tapered pilot of lock ring installer, center pilot in end of pinion shaft, press ring off pilot and into groove in shaft). Install spacer on front end of pinion shaft, position pinion bearing retainer on hub of pinion shaft flange and install assembly on pinion shaft, assemble shaft washer and nut, tighten nut to 160-280 ft. lbs. (use torque wrench), install cotter pin.

Bearing Retainer Oil Seal—To replace oil seal, soak new oil seal and packing in engine oil, make certain that lip of leather seal is in toward pinion bearing, press seal and packing in place in retainer using J-2231 Oil Seal Replacer.

Pinion Setting (All 1½ & 2 Ton Trucks): Pinion position not adjustable. Double row ball bearing seats against shoulder in carrier and is retained by bearing retainer. *CAUTION*—Bearing must be installed so that extended portion of inner race is toward back of the pinion gear teeth.

Pinion Setting (¾ & 1 Ton Trucks): Pinion position controlled by shims installed in pinion bearing counterbore in carrier. When disassembling axle, note number and thickness of shims installed and re-install same number and thickness of shims if old ring and pinion gear being re-used. If new gears being installed, use one .015" shim, one .018" shim (.033" total which is average shim thickness) as a standard starting set-up, check gear mesh when axle completely reassembled. Shims furnished in thicknesses of .012", .015", .018", .021".

Differential Bearing Assembly:—Bearings are press fit on differential case hubs. Use special puller to remove bearings (puller fingers must fit in notches in case so that pressure applied to inner races only). Mark differential case halves before dis-assembly to insure reassembling in same position—this is very important. Remove twelve ½" bolts holding case halves and ring gear together, lift off case cover, remove differential pinions and side gears, tap ring gear off case with soft-faced hammer. When reassembling, oil pinions and side gears and install in left side of case, assemble right side of case being careful to line up marks made before disassembly, install guide pins in two opposite bolt holes (guide pins can be made up of two #3652253 ring gear screws with heads removed and end slotted to permit removal). Make certain that ring gear seat on case is clean and not burred, install ring gear on guide pins, install bolts in all holes (except guide pin holes), tighten all bolts evenly and securely until ring gear face is flush with flange on case, remove guide pins, install remaining bolts and tighten all bolts with a torque wrench to 85-95 ft. lbs. Use special driver J-2226 (¾ & 1 Ton), J-1488 (Other Trucks) to install differential side bearings on case hubs (wide side of inner race in).

Differential Bearing Adjustment:—When installing differential assembly in carrier, make certain that bearing cap marks line up with marks n carrier. tighten bearing capscrews until lock washers just flatten out, screw both bearing adjusting nuts up until snug to seat bearings. Back off right hand adjusting nut, tighten left hand nut until all clearance or backlash between ring gear and pinion is just taken up, then back off adjusting nut two notches to locking position (slot in nut in line with lock). Tighten right hand adjusting nut solidly, back nut off until free of bearing, then tighten right hand adjusting nut until all play in bearing is taken up, and then tighten nut one to two notches more to locking position, tighten bearing cap screws with a torque wrench to 95-105 ft. lbs. (¾ & 1 Ton), 130-160 ft. lbs. (Other Trucks), install adjusting nut locks. Check ring gear backlash as follows:

Ring Gear Backlash Adjustment—If backlash not correct after setting up bearings as directed above, loosen left hand adjusting nut one notch and tighten right hand nut one notch if backlash less than .005", or loosen right hand nut one notch and tighten left hand nut if backlash exceeds .008". In making backlash adjustments, both adjusting nuts must be turned an exactly even number of notches (in an opposite direction) to avoid disturbing bearing adjustment.

Ring Gear Thrust Pad Adjustment:—Examine bronze tip on ring gear thrust pad and replace if worn. To adjust, tighten thrust pad adjusting screw until bronze tip engages back of ring gear lightly (turn gear while making adjustment), then back screw off 1/12 turn, hold screw from turning and tighten locknut. This adjustment will give clearance of .005-.007" between thrust pad and ring gear.

CHEVROLET TRUCK (HEAVY DUTY)

2-T n L w Cab F rward Models (1955). Std.
2-T n (Exc. L w Cab F rward) (1955). Optl.

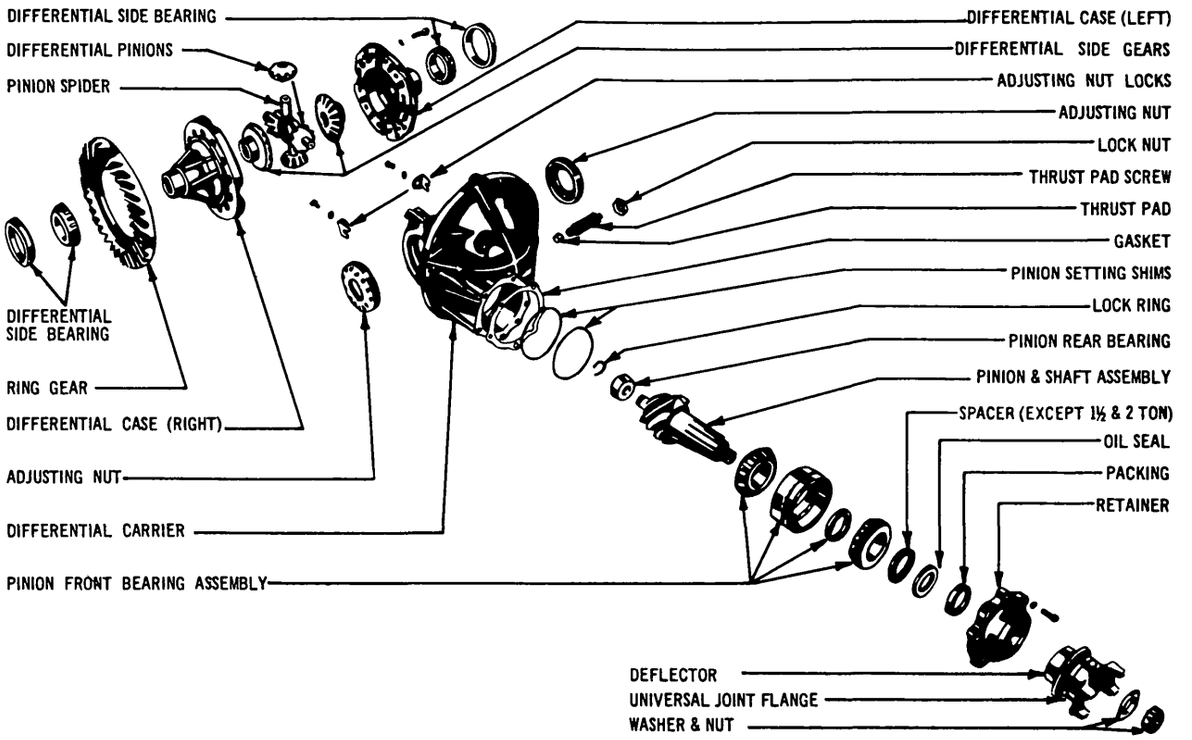
DESCRIPTION: Full-floating, hypoid gear type with roller bearing mounted pinion shaft, and Hotchkiss drive.

REAR AXLE ASSEMBLY REMOVAL: *See "Rear Axle" n Truck Mod l pag s.*

AXLE SHAFT REMOVAL: *See "Rear Axle" on Truck M d l pages.*

►*REAR AXLE OVERHAUL NOTE: Repairs and adjustments can b mad without removing complete ass mbly from truck.*

DIFFERENTIAL CARRIER ASSEMBLY: Removal–Drain lubricant from axle housing and remove housing cover and axle shafts (see "Axle Shaft Removal" on Truck Model pages). Remove two trunnion bearing "U" bolts from rear axle yoke and split the rear universal joint (tape bearings in place). Swing propeller shaft to one side and tie to frame side rail. Remove bolts and lockwashers retaining carrier assembly to axle housing. Support carrier assembly with a floor jack and roll from under truck.



DIFFERENTIAL CARRIER ASSEMBLY: Disassembly–Mount the assembly in a bench vise or holding fixture and\proceed as follows:

Diff r ntial & Ring G ar: Removal–Loosen ring gear thrust pad locknut and remove thrust pad. Remove differential adjusting nut locks, bearing cap bolts and lockwashers. Remove bearing caps and adjusting nuts by tapping on bosses of caps until free of dowels. *(CAUTION*–Do not use screwdriver to pry caps off as this may damage machined face of cap). Remove differential and ring gear from carrier.

Disassembly–Install differential bearing puller TR-278-R making sure that puller legs are fitted securely in case and that retaining yoke is tight. Remove bearings. Check differential case to make sure that both halves are marked so they can be reinstalled in the same relative position. Remove twelve bolts holding both halves together *(NOTE*–Ring gear is mounted on one half of case), and remove differential side gears, thrust washers, differential pinion gears, thrust washers and differential pinion spider.

Pini n G ar & Shaft: R m val–Remove bolts attaching pinion bearing retainer to carrier housing. Tap on universal joint flange while oil seal retainer bolts are being loosened to gradually bring pinion assembly out of housing (or use adapter J-6187 and sliding hammer after cotter pin, nut and flat washer are removed from pinion). Remove shims from housing.

Disass mbly–Clamp pinion shaft drive flange in bench vise and remove cotterpin, nut, and flat washer from end of pinion shaft. Remove drive flange and bearing retainer assembly from shaft. Drive out old seal from retainer housing and remove felt packing. Press off double row thrust bearing using tool J-6203 on 6 tooth pinion and J-6171 on 5 tooth pinion. Press off rear inner race from end of pinion shaft using press plate holder J-358-1 and remover plate J-1453.

CHEVROLET TRUCK (HEAVY DUTY) HYPOID REAR AXLE

DIFFERENTIAL CARRIER ASSEMBLY: Inspection, Reassembly and Installation–Proceed as follows:

Pinion Gear & Shaft: Inspection–Wash all parts in solvent. Inspect splines of shaft for wear and pinion teeth for scoring, cracked or chipped teeth. Inspect double thrust bearing and rear pinion bearing for roughness. Inspect deflector on "U" joint flange for distortion or looseness.

Reassembly–Press on rear inner race and double thrust bearing. Install new felt packing and oil seal in bearing retainer using Installer tool J-6078 *(CAUTION*–Soak new seal and felt packing in engine oil to provide initial lubrication). Install new deflector on "U" joint flange (if necessary), using tool J-6081. Install bearing retainer on pinion shaft. Place "U" joint drive flange on pinion shaft and place the assembly in a bench vise. Install the flat washer and nut retaining flange to pinion shaft and tighten nut to 160-280 ft. lbs. *(CAUTION–Do not back off nut to install cotter pin).*

Installation–Install same amount of shims as removed, in differential carrier housing *(NOTE–If new pinion and gear set, or old pinion requires r s tting, see "Pinion Setting" below).* Install pinion assembly and new gasket in carrier housing by tapping on "U" joint drive flange at the same time as bearing retainer bolts are being installed and screwed into carrier housing. Tighten all bearing retainer bolts to 85-90 ft. lbs.

Differential & Ring Gear: Inspection–Wash all parts in clean solvent and inspect ring gear for cracked or worn teeth. Inspect case and cover, side gears and thrust washers, differential pinion gears and thrust washers for scoring or wear. Check fit of side gear hubs in case and cover, and check splines of side gears for excessive wear. Inspect side gears and pinions for worn, cracked or chipped teeth. Inspect spider for scoring and check pinion fit on spider hubs. Inspect differential case bearings for cracked or checked, scored or broken races and rollers. Check bearings for roughness.

Reassembly–If ring gear has been removed from differential case, install two guide pins (9/16"-18x2" long cap screws with heads cut off and end slotted) to ring gear diametrically opposite each other. Start guide pins through case flange holes and tap ring gear on to case. Lubricate differential side gears and pinions and place differential pinions on spider. Assemble side gears and pinions and spider to left half of differential case. Assemble right half of case to left half, being sure to line up aligning marks. Install differential-to-ring gear bolts and lockwashers and tighten evenly until ring gear is flush with case flange. Remove guide pins and install two remaining bolts. Tighten all bolts to 150-170 ft. lbs. Place differential side bearing on hub with thick side of inner race toward case and drive

CONTINUED ON NEXT PAGE

CHEVROLET TRUCK HEAVY DUTY (C nt.)

in place using bearing driver J-6080 *(NOTE*–This tool is counterbored and has a pilot to assure proper installation and seating of bearing).

Installation–Position differential side bearing outer races on differential bearings and place differential assembly in bosses of differential carrier housing. Install left and right adjusting nuts *(CAUTION–Carefully slide nuts alongside the bearings so that threads on nuts fit into threads in carrier).* Install differential bearing caps making sure that marks on cap are aligned with marks on carrier. Install bearing cap bolts and lockwashers and tighten until lockwashers just flatten out *(NOTE–Bolts will be retightened to correct torque after backlash and pinion setting is checked and adjusted).*

Backlash Adjustment: Loosen right hand adjusting nut and tighten left hand adjusting nut using wrench J-972 while returning ring gear. Continue tightening left hand nut until all backlash between ring gear and pinion is removed . Back off left hand nut approximately two notches to point where notch in nut is aligned with lock. Tighten right hand nut firmly to force differential in solid contact with left hand nut. Loosen right hand nut until it is free of its bearing; then tighten right hand nut from one to two notches more to a position in which a notch is nut aligns with lock *(NOTE–The above procedure provides the proper preload on the differential side bearings).* Mount a dial indicator on carrier and check the backlash between ring gear and pinion. Correct backlash is .005-.008". If backlash is more than .008" loosen the right hand adjusting nut one notch and tighten left hand nut one notch. If backlash less than .005" loosen the left hand adjusting nut one notch and tighten the right hand nut one notch.

Pinion Setting: Coat ring gear teeth lightly with red lead or Prussian blue, then turn the pinion shaft several revolutions in both directions to establish a gear pattern on the ring gear. Examine pattern on ring gear teeth. If pinion depth is correct, the tooth pattern will be centered on the pitch line and toward toe of ring gear. If pattern is below pitch line on ring gear teeth, the pinion is too deep and it will be necessary to remove pinion and **increase** the shim thickness between pinion bearing and differential carrier housing. If the pattern is above pitch line, it will be necessary to **decrease** shim thickness in carrier housing. *(NOTE–*Changing the pinion depth will make some change in backlash and it may be necessary to readjust the backlash (see above). Tighten bearing capscrews to 130-160 ft. lbs. Recheck backlash and install adjusting nut locks.

Thrust Pad Adjustment: Install thrust pad and tighten screw until bronze tip engages back face of ring gear until rotating gear. Back off screw one twelfth (1/12) turn and tighten locknut. *NOTE*–Make sure screw does not change while tightening locknut. This adjustment provides .005-.007" clearance between thrust pad and ring gear face.

1947-55 CHEVROLET TRUCK TWO-SPEED HYPOID GEAR

1½ & 2 Ton Truck Models (1947-55)①. Optional.

①—1955 1st Series Trucks only. "1955 Chevrolet Truck 2-Speed" used on 1955 2nd Series Trucks.

►**Axle Shaft Differential Side Gear Note**—Beginning with 1952 production, axle shaft and differential side gears have 27 splines and are interchangeable with axle shafts on 1952 Two-Ton Single Speed Axle.

►CHANGES & CORRECTIONS

►**DIFFERENTIAL & AXLE PRODUCTION CHANGE (Late 1952)**—Starting with rear axle No. VN-414, differential spider replaced with heavier type unit, Part No. 3699589. Later type unit requires different right hand axle shaft than earlier type. Later type axles and spider gears can be used as service replacement on 1946-51 Two-Speed axles by changing spider and both axle shafts.

BRAKE DRUM REPLACEMENT: (1947-50 Models)—Brake drum held to hub by bolts which must be pressed out or driven out with a hammer. When replacing drum or hub, gasket between inside of brake drum and oil deflector must be coated with heavy shellac or paint on both sides to prevent oil leaking onto braking surface of drum. Small hole in gasket and channel in oil deflector must be lined up with oil relief hole in drum. When installing new bolts, press bolts in until they have bottomed and have locked tight in drum. CAUTION—Check to make sure bolts will not turn in holes.

1951-55 Trucks—Brake drum is held to hub by three slotted screws which can be removed and replaced with a screw driver. Be sure to place soft paper gasket between hub and drum.

►**REPLACEMENT REDUCTION GEAR INSTALLATION CAUTION:** Reduction gear mounting bolt holes in replacement differential case and cover are drilled undersize (35/64" drill) and must be reamed at assembly with a 9/16" reamer using the gear as a pilot. Ream one hole, then install bolt to hold gear and case or cover in correct position while reaming remaining holes. **When replacing reduction gear,** install all bolts which can be inserted without forcing, then ream remaining holes with 9/16" reamer, using gear holes as pilot for reamer.

DESCRIPTION: Hypoid Gear, double-reduction type with conventional first reduction hypoid ring and pinion gear and a second reduction consisting of two helical gears on the ring gear shaft (short separate shaft in front of differential case and axle shafts) which mesh with two larger gears on the differential case. These second reduction gears are constant-mesh type and one set at a time is engaged by the shifting sleeve on the ring gear shaft between the gears. Shifting sleeve locks the gear to the shaft and is actuated by the Vacuum Shift Control diaphragm as follows:

Vacuum Shift Control: Consists of a double-acting diaphragm type vacuum power cylinder mounted on axle carrier housing and linked directly to the double reduction gear shifter sleeve. Diaphragm pushrod is spring-loaded in the piston rod with spacers and stopwashers which limit pushrod travel. This enables the gear ratio to be "pre-selected" by movement of the selector valve on the instrument panel. When selector valve is moved to "Lo" or "Hi" range, a corresponding movement of the diaphragm and pushrod compresses the spring, and as soon as torque is relieved (by momentary letting up on accelerator pedal), the spring moves the piston rod and completes the shift. Shifting sleeve is centered in "Lo" and "Hi" positions by 3 spring-loaded poppet balls in the sleeve hub.

REMOVAL OF AXLE: ***See "Rear Axle" on car model page for removal of carrier assembly from truck.***

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: Same as for full-floating truck axle. ***See "Chevrolet Truck Hypoid (Full-floating)" Rear Axle.***

VACUUM SHIFT CONTROL: Following operations can be performed without disassembling rear axle:

Vacuum Cylinder Diaphragm Replacement: Disconnect hoses at fittings on vacuum cylinder. Remove bolts holding two cylinder halves together, lift off outer half. Remove outer nut on pushrod **while holding inner nut stationary** with ½" wrench. Remove diaphragm plates and diaphragm. Reassemble new diaphragm in same manner using Permatex around pushrod hole in diaphragm plates to insure a good seal at this point. Check shifting operation in "Lo" and "Hi" range after unit reassembled.

►***CAUTION—Do not transpose hose connections.***

Oil Seal Replacement: Dismantle vacuum cylinder and remove diaphragm (see above). Remove nuts and washers on two mounting studs, lift inner half of vacuum cylinder off axle housing, drive old oil seal out. Soak new seal in engine oil, coat outer diameter of seal with permatex and install in cylinder with free side of leather down (in), press seal in place with tool J-968. Install inner half of cylinder on axle housing, reassemble diaphragm.

Shifter Spring Replacement: Dismantle vacuum cylinder and remove diaphragm (see Diaphragm Replacement above). Press in on end of pushrod to relieve spring pressure, remove snap ring from inner rim of piston rod, withdraw pushrod assembly. Clamp head of pushrod bolt in vise, remove two nuts, short spacer, stop washer, spring, long spacer, and stop washer from pushrod bolt. Reinstall parts in same order using a new spring. Tighten adjusting nut on pushrod until distance between outer faces of stop washers is 3½", install and tighten locknut being careful not to change adjustment. Lubricate inside of piston rod with engine oil, install pushrod and replace snap ring. Reassemble vacuum control.

DIFFERENTIAL CARRIER DISASSEMBLY: Mark differential bearing caps and carrier to insure reassembly in same position. Remove adjusting nut locks, adjusting nuts, and bearing caps, lift differential assembly out of carrier. Remove nuts on pinion cage mounting studs, take out lubrication plug. Install two 3/8" bolts in tapped holes in pinion cage flange, turn nuts up evenly to remove cage assembly. **Note number and thickness of shims under carrier flange** (these shims control pinion mesh). Loosen locknut on bolt attaching shifter fork to vacuum control piston rod, remove bolt. Remove nuts on vacuum cylinder mounting studs, remove cylinder, piston rod, mounting sleeve and shims (tap on end of piston rod to free it from shifter fork). Remove nuts on double reduction shaft bearing caps, remove caps and shims (use

CONTINUED ON NEXT PAGE

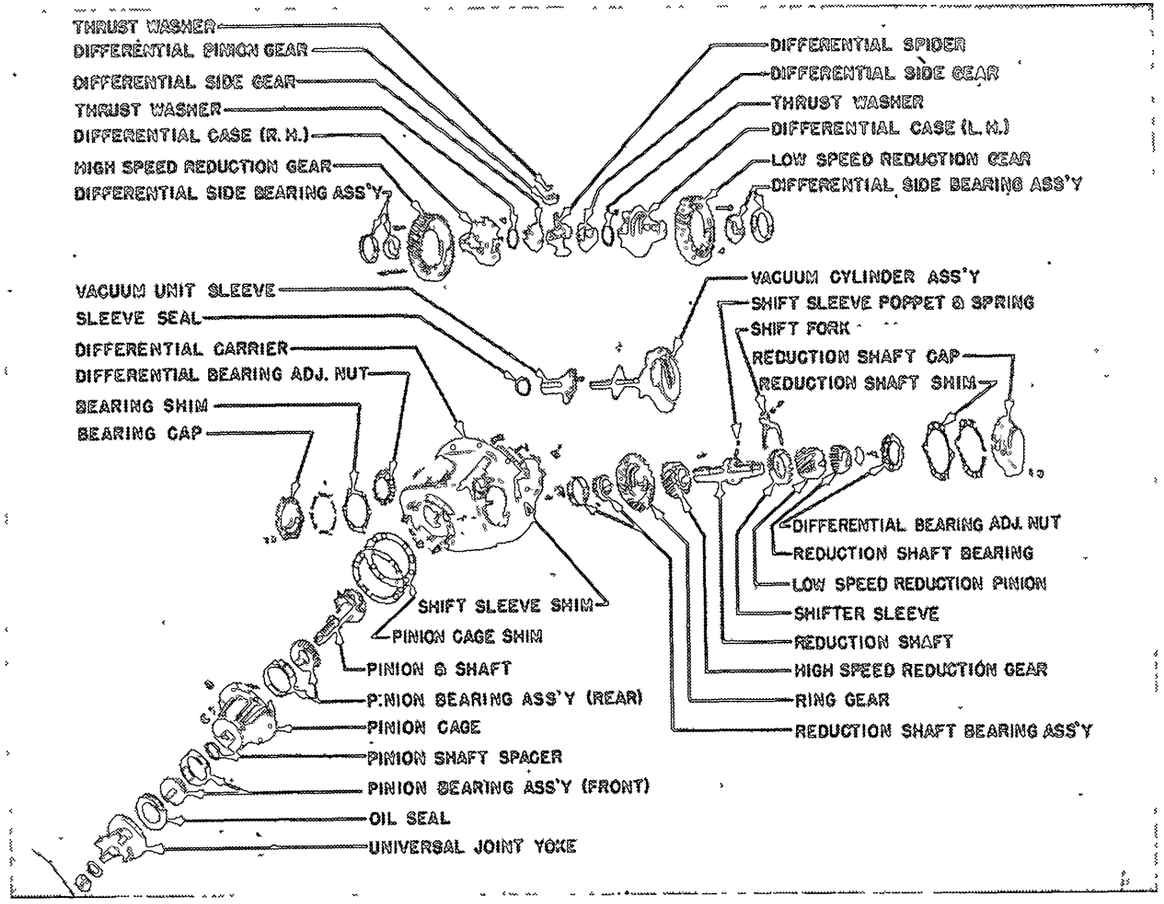
1947-55 CHEVROLET TRUCK TWO-SPEED HYPOID GEAR (Cont.)

two 3/8" capscrews in tapped holes in left bearing cap to remove cap), note number and thickness of shims removed at each bearing cap (these shims control ring-and-pinion gear backlash and bearing adjustment). Slide double reduction shaft assembly to left and pull ring gear end to rear to clear differential bearing support, remove shaft assembly. Remove right bearing outer race by driving race through into carrier with driver J-872-1. Do not remove left bearing race (race is pressed in bearing cap and these parts furnished as an assembly). Disassemble and service the major sub-assemblies as follows:

Pinion Cage Disassembly & Reassembly: Remove nut on end of pinion shaft, remove universal joint flange. Support carrier end of pinion cage in arbor press, press pinion and rear bearing out of cage, remove bearing spacer from pinion shaft. Press front bearing and oil seal out of cage. To remove bearing from pinion shaft, use Pinion Bearing Remover J-2228 to prevent damage to bearing while pressing shaft out. Use long drift to drive bearing outer races out of pinion cage. Install new races in cage using special driver J-5676 (front race), J-5677 (rear race). Lubricate all parts before re-installing, make certain that bearing spacer in place on shaft between bearings, install universal flange but do not install oil seal until after bearing pre-load adjusted, tighten pinion nut to 75-150 ft. lbs., check and adjust bearing pre-load as directed below. After pre-load adjusted, soak new oil seal in engine oil, install oil seal with driver J-971 with free edge of seal toward bearing. Re-install universal flange, install cotter pin (CAUTION—do not back nut off washer, and nut, tighten nut to 75-150 ft. lbs. and to align cotter pin hole, stop tightening the nut at point where slot lines up with hole).

Pinion Bearing Pre-load Adjustment—Check pre-load by clamping pinion cage flange in vise and using spring scale and rod to measure torque required to turn pinion (pinion nut must first be correctly tightened to 75-150 ft. lbs.). Turning torque should be 12-18 in. lbs. (or 1-1½ ft. lbs.). Adjust by installing spacer or shims of correct thickness on shaft between bearings (thinner shims will increase turning torque, thicker shims decrease turning torque). These adjusting shims furnished in seven thicknesses as listed below and combinations of two shims will provide necessary range of adjustment from .316" to .354" in .002" steps.

Adjusting Shim Part Nos.—3847424—.157", 3847425—.159", 3847426—.163", 3847427—.167", 3847428—.171", 3847429—.175", 3847430—.177".



Double Reduction Shaft Disassembly & Reassembly: Remove capscrew and bearing retainer washer on each end of shaft, support tooth side of ring gear on hardwood blocks in arbor press, press shaft out of ring gear and bearing. Remove high speed pinion, shifter sleeve and poppet balls and springs (CAUTION—balls and springs will fly out as sleeve is removed). Replace sleeve on shaft with tapered side against pinion, support sleeve on hardwood blocks in arbor press, press shaft out of bearing, lift off bearing and low speed pinion. When reassembling, lubricate all parts for initial lubrication, install high speed pinion with clutch teeth toward splines on shaft, see that ring gear key in place in shaft, press shaft in gear until shoulder on shaft is against gear, press bearing on shaft against gear, install bearing retainer washer and capscrews, tighten capscrews to 37-46 ft. lbs. and secure with lockwire. Install poppet springs and balls in shaft holes, install shifter sleeve on shaft with heavy tapered end of sleeve toward ring gear and three tapered teeth on sleeve in line with poppet balls. Install low speed pinion, press bearing on shaft firmly against shoulder, install bearing retainer washer and capscrews, tighten capscrews to 37-46 ft. lbs. and secure with lockwire.

Differential Disassembly & Reassembly: Mark halves of case to insure correct reassembly. Remove nuts on eight long through-bolts, separate differential case halves, remove differential side gears, pinions, and thrust washers. To remove side bearing cone and roller assemblies, install J-1318 Differential Bearing Puller on bearing, support differential case in arbor press with bearing puller down, use drift inserted through case to press puller and bearing down off case hub. Press new bearings on hub firmly against shoulder on case using J-1312 Bearing Replacer. To replace double reduction gears, remove gear mounting nuts and bolts, tap gear off case, make certain that mating flanges of case and new gear are clean and smooth, tap gear in place, tighten mounting bolt nuts evenly to 70-110 ft. lbs. and secure with lockwire.

CAUTION—Double reduction gear mounting bolt nuts should be at inner face of differential case halves, nuts on long through-bolts should be on left side or AWAY from ring gear.

DIFFERENTIAL CARRIER REASSEMBLY: Reverse disassembly directions and make the following adjustments during the reassembly operations:

Double Reduction Shaft Bearing Adjustment: Install assembly with same thickness of shims under each bearing cap as were removed during disassembly (install left cap first, tighten mounting stud nuts securely). With correct bearing adjustment, shaft should rotate with slight drag (bearing pre-load only—pinion must be out so that no pinion drag added). Adjust by adding or removing shims at right or left bearing cap (shims will be transferred from one side to the other during ring-and-pinion

CHEVROLET TRUCK TWO-SPEED HYPOID GEAR AXLE—WITH VACUUM CONTROL

CONTINUED ON NEXT PAGE

1947-55 CHEVROLET TRUCK TWO-SPEED HYPOID (Cont.)

gear backlash adjustment). After backlash adjusted, tighten all bearing cap nuts to 75-95 ft. lbs.

Ring-and-Pinion Gear Mesh (Pinion Setting Adjustment): Install pinion cage in carrier with same thickness of shims under cage flange as were removed during disassembly, install nuts on 3 equally spaced mounting studs and tighten nuts securely. Check gear mesh by painting ring gear teeth with red lead or Prussian blue, rotate pinion by hand in both directions while pressing on back of ring gear to apply a load. Make necessary adjustment of pinion position for correct mesh by adding shims (to move pinion out), or removing shims (to move pinion in) from beneath pinion cage flange. These shims furnished .003", .005" thick. After adjusting pinion position and backlash (see below), install all pinion cage mounting stud nuts and tighten evenly to 115-130 ft. lbs.

Ring-and-Pinion Gear Backlash: Check backlash with dial indicator mounted on carrier. Backlash should be .008-.013". Adjust by transferring shims from under one double reduction shaft bearing cap to the other keeping total shim thickness constant to avoid disturbing bearing adjustment (move shims from left to right side to increase backlash, from right to left side to decrease backlash). These shims furnished .003", .005" thick. After adjustments completed, tighten bearing cap nuts to 75-95 ft. lbs.

Two-speed Shifter Mechanism Installation: With shifter sleeve in low-speed position, install shifter fork in sleeve with lock bolt hole toward rear of carrier. Place rubber oil seal on vacuum unit mounting sleeve and install sleeve in carrier with same thickness of shims under sleeve flange as were removed when unit disassembled. Use new gasket on vacuum cylinder piston rod, insert rod and cylinder assembly in sleeve, enter end of rod in shifter fork and line up hole in rod and fork, install taper bolt and tighten locknut securely. Tighten cylinder mounting stud nuts. Check assembly as follows:

Shifter Mechanism Adjustment—With shifter sleeve in low-speed position, check clearance at each side of shifter fork with a feeler gauge. If clearance less than .010" at either side of fork, loosen vacuum cylinder mounting nuts, add or remove shims from under mounting sleeve flange (shims slotted, not necessary to remove cylinder or sleeve), tighten nuts and recheck shifter fork clearance.

Differential Bearing Adjustment: When installing differential assembly, assemble adjusting nuts and bearing caps in accordance with marks. Tighten bearing cap stud nuts just snug. Shift differential to right or left (by turning up one adjusting nut and backing off opposite nut) until double reduction gears and pinions are centered. Position one adjusting nut in a locking position (slot in line with lock tang), tighten opposite adjusting nut until all clearance or endplay just removed, then tighten each adjusting nut one additional notch for correct bearing pre-load. Tighten bearing cap stud nuts evenly to 150-170 ft. lbs., install adjusting nut locks, secure bearing cap nuts with lockwire.

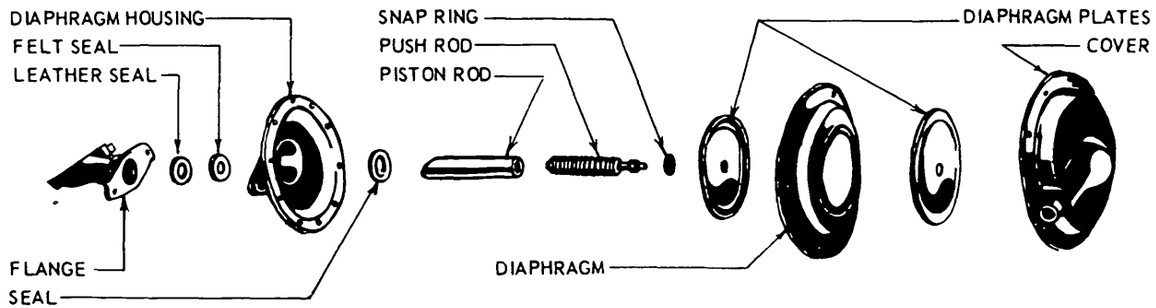
1955 CHEVROLET TRUCK TWO-SPEED HYPOID GEAR

Chevrolet 2nd Series 1½ & 2-Ton Trucks (1955) Optl.

DESCRIPTION: Vacuum controlled 2-speed planetary-reduction type with hypoid primary gears and four planetary pinions. A five tooth and a six tooth drive pinion are used with a correct mating ring gear to furnish two different ratios.

OPERATION: In low range operation the primary (hypoid) reduction is multiplied by a planetary system reduction of approximately 1.36-1 for final drive. The secondary reduction occurs only when the sun gear is held stationary, the four planets then being driven around the sun gear by internal teeth in the large case bolted to the ring gear. Planet journals are integral with the planet support and the differential and planet support cover. The orbit speed of the planets is conveyed to rear wheels through cover, differential pinions, differential side gear and axle shafts. Control of the sleeved sun gear is through lateral movement of a coaxial "shifter sleeve" splined over the sun gear. Left hand movement of shift collar and sleeve causes sun gear to stop when dove-tail teeth in an anchor ring attached to housing engage similar teeth on approaching face of shifter sleeve. Right hand movement of shifter collar and sleeve by the vacuum control mechanism results in release from the anchor ring. Clutching teeth on opposite face of shifter sleeve then mesh with dove-tail teeth projecting from differential and planet support case and ring gear assembly. Thus engaged, the sun gear must turn at speed of ring gear, the planets are locked in place and only the reduction afforded by primary drive gears determine rear wheel speed. A positive, quick acting, two way vacuum system actuates the shift collar and sleeve. The hand control is located on the gear shift lever.

DIFFERENTIAL CARRIER ASSEMBLY: Removal—Drain rear axle housing and remove hub caps. Remove jaws from Sliding Hammer J-1436 (Rear Axle Shaft Bearing & Oil Seal Remover) and install adapter J-1436-8 to puller handle. Install axle shaft puller into hole provided in end of axle shaft and pull shaft (both sides) out about 8" to clear differential. Remove clamps and hose assembly at vacuum cylinder and slip hoses off fittings. Split rear universal joint by removing trunnion bearing "U" bolts from rear flange. Slide propeller shaft assembly forward and tape universal joint bearing to prevent bearings falling out. Swing propeller shaft to one side and tie it to frame side rail. Remove capscrews attaching differential planet and carrier to axle housing *(NOTE*—Before removing last capscrew, place a long drift punch through upper hole in assembly to give it support during removal). Place a roller jack under assembly using a wood block as necessary to support the unit. Work assembly forward until it clears housing, then remove it from under truck.



DIFFERENTIAL CARRIER ASSEMBLY: Disassembly—Proceed as indicated below.

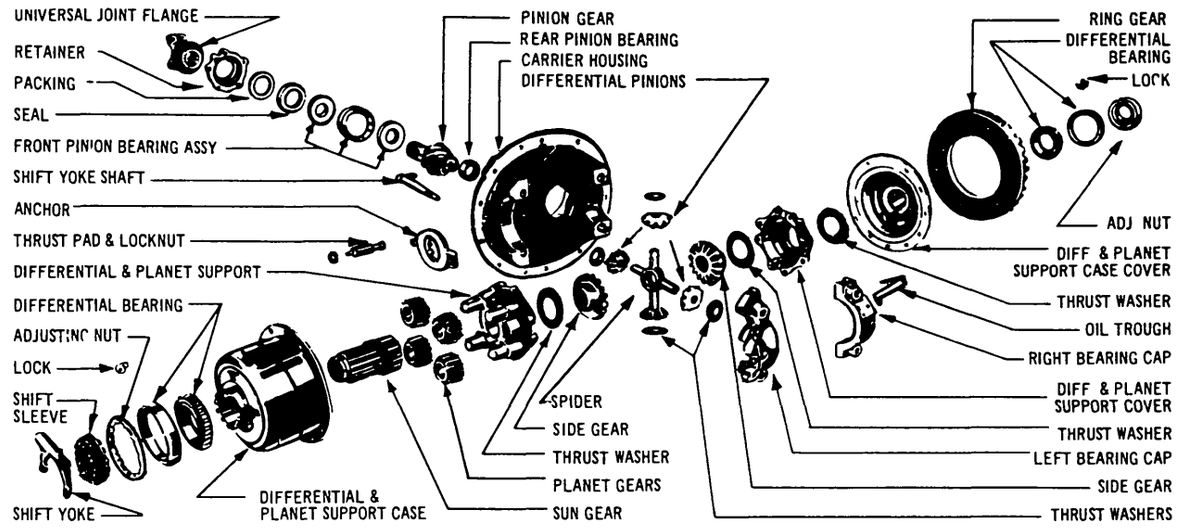
Vacuum Cylinder: Removal—Remove three bolts and lockwashers securing cylinder assembly to carrier housing and remove cylinder assembly.

Disassembly—Remove two nuts and bolts retaining diaphragm housing to flange and separate housing from flange. Unscrew screws and self-locking nuts securing diaphragm cover to housing and separate cover and housing. Using two half inch open end wrenches, remove nut securing diaphragm plates and diaphragm to pushrod assembly. Separate plates and diaphragm. To disassemble pushrod assembly, compress spring of pushrod, remove snap ring from inside diameter of piston rod, and pull pushrod out of piston rod.

Differential & Planet Unit: Removal—Remove differential and planet assembly anchor from left side of assembly. Loosen locknut on ring gear thrust pad and remove pad. Drive out shifter yoke shaft using a drift punch and a hammer. Slide shifter yoke and sleeve to left and remove from end of sun gear. Remove retaining bolts and washers from adjusting nut locks and remove locks from both sides. To remove oil trough, bend tabs downward, remove two bolts and remove trough and locking plate. Remove bolts and lockwashers securing bearing caps and tap caps off dowels in mounting bosses with a soft hammer. Remove adjusting nuts. Lift differential and planet assembly out of carrier housing using extreme care not to drop side bearing outer races.

CONTINUED ON NEXT PAGE

CHEVR LET 2-SPEED AXLE SHIFT ASSEMBLY



1955 CHEVROLET TRUCK TWO-SPEED (Cont.)

Disassembly–Mark ring gear, support case and case cover for alignment by scribing lines on case, cover and gear. Remove the twelve bolts retaining ring gear, case, and cover and lift off case assembly. Remove sun gear and planet gears *(CAUTION–Mark or tag all gears so they may be reassembled exactly as removed. If necessary to replace planet gears, the complete set of gears must be replaced).* Lift differential and planet support off case cover. Remove the eight bolts and lockwashers connecting planet support and cover and separate the two parts *(NOTE*–The support and cover are stamped on all four sides with matching numbers to aid in reassembly).. Remove spider, pinion gear and thrust washers, and tag all parts as removed. Remove right and left hand side gears and thrust washers from each side of housing. Remove differential bearings from differential and planet support case and case cover.

Pinion Gear & Shaft: Removal–Loosen bolts and lockwashers securing pinion assembly to differential carrier until bolt heads contact the universal joint flange. Gradually tap pinion assembly outward while loosening bolts to avoid interference with companion flange *(NOTE*–If universal joint flange is removed from pinion assembly, the pinion assembly can be removed by using adapter J-6187 with Slide Hammer J-1436). **Disassembly**–Remove shims from differential housing and note the amount used to assure reinstallation of the same number. Remove rear bearing from differential. Place universal joint flange in a vise and remove cotter pin, nut and flat washer securing flange to pinion and remove flange. Drive oil seal out of retainer housing and remove felt washer (discard oil seal). Press inner race off end of pinion using tool J-1453 and holder J-358-1. Using tool J-6171 (5 tooth pinion), or J-6079 (6 tooth pinion), press double thrust bearing off pinion with an arbor press.

DIFFERENTIAL CARRIER ASSEMBLY: Inspection, Reassembly & Installation–Proceed as follows

Pinion Gear & Shaft: Inspection–Wash all parts in solvent. Examine pinion teeth for chips, cracks, and wear and check splines for wear. Check thrust bearing for worn or pitted rollers or bearing race. Inspect universal joint flange for cracks or worn splines and examine oil seal retainer housing for cracks and defective sealing surface. *NOTE*–If oil seal removed, replace with a new seal. Check rear bearing for worn or pitted rollers. Inspect oil deflector on universal joint flange for bends or other damage. Replace if necessary. **Reassembly**–Install inner race on end of pinion shaft. Lubricate and press double thrust bearing onto pinion shaft. Install new felt washer and seal in pinion bearing oil seal retainer using Seal Installer J-6078. Place rear pinion bearing in differential carrier housing. If oil deflector on universal joint flange requires replacement, tap off old deflector and install a new one, using Installer J-6081. Install oil seal retainer on pinion shaft. Insert a bolt and lockwasher through each hole in oil seal retainer and then position universal joint flange on pinion shaft. With universal joint flange in a vise, install flat washer and nut on pinion and tighten to 180-250 ft. lbs., and install cotter pin *(CAUTION–Do not back off nut to install cotter pin).*

CHEVROLET TRUCK 2-SPEED REAR AXLE

Installation–Install rear pinion bearing in carrier housing and install same amount of shims as removed against shoulder in carrier housing *(NOTE–If new pinion and gear set to be installed, or old pinion requires resetting, see "Pinion Setting" below).* Position pinion assembly in carrier housing and tap inward with a soft hammer until retaining bolts can be started in housing. Tighten retaining bolts to 85-95 ft. lbs.

Differential & Planet Unit: Inspection–Wash all parts in solvent (do not use air to dry bearings). Inspect ring gear, planet gears, differential pinion gears, and sun gear for damaged teeth or excessive wear. Inspect thrust washers for excessive wear. Inspect spider for wear or scored pinion bearing area. Inspect differential side gears and thrust washers for damaged teeth or excessive wear.

►*PARTS REPLACEMENT CAUTION:* If necessary to replace any single component in the following groups, all parts in each group must be replaced· (a) Sun gear and four planet gears. (b) Spider, four differential pinion gears, and thrust washers. (c) Ring gear and pinion. (d) Differential bearing and race.

Reassembly–Install differential bearings on differential and planet support case and case cover. Use Bearing Installer J-6080 to install bearing on case cover, and J-6175 to install bearing on case. Position side gear thrust washers on hubs of side gears and install one side gear in differential and planet support and one in differential and planet support cover *(NOTE–Gear with the longer hub is installed in the cover).* Assemble the four pinion gears and thrust washers on the spider, being sure to reinstall gears in their original positions. Install the assembled spider and gears in differential and planet support so that identification numbers on spider and planet support match. Lubricate gears and thrust washers with SAE 90 Multi-purpose gear lubricant. Position support cover with matching identification marks aligned and install eight bolts and lockwashers. Tighten bolts to 70-110 ft. lbs. Install four planet gears on journals of differential and planet support *(CAUTION–Gears must be installed with radius on gears toward the planet support).* Mesh sun gear in planet gears. Place ring gear, teeth down on wood block and install four Guide Pins J-6154 in every third hole of the ring gear. With the assembly marks aligned, install differential and planet support case cover onto guide pins. Position support cover thrust washer on hub of side gear, then place planet assembly in differential and planet support case cover, with sun and planet gears upward. Install planet support case over guide pins, making sure that alignment marks are in line, and loosely install eight of the twelve retaining bolts. Remove guide pins and install the other four bolts. Tighten all bolts in rotation to 85-95 ft. lbs.

Installation–Position differential side bearing outer races on differential bearings and place differential and planet assembly in bosses of differential carrier housing. Install left and right adjusting nuts. Tap bearing caps onto dowels in bosses of differential carrier housing and then secure with bolts and lockwashers. Tighten bolts until lockwashers just flattened *(CAUTION*–Bolts will be retightened to correct torque after backlash and pinion setting is checked and adjusted).

Backlash Adjustment–Loosen right hand adjusting nut and tighten left hand nut, Use Differential Adjusting Wrench J-972 on the right side and a drift and hammer on the left side. *(NOTE*–Left side nut has internal notched teeth so that adjusting wrench cannot be used). Continue tightening left hand nut until all backlash is removed between pinion and ring gear. Back off left hand nut approximately 2 notches to a point where notch in nut is aligned with lock. Tighten

CONTINUED ON NEXT PAGE

1955 CHEVROLET TRUCK TWO-SPEED (Cont.)

right hand nut firmly to force differential and planet assembly in solid contact with left hand nut. Loosen right hand nut until it is free of its bearing, then tighten nut snugly against bearing. **Tighten right hand nut from ne to 2 notches more** to a point where notch in nut aligns with lock (*NOTE*–This procedure provides for proper preload on bearings). Mount a dial indicator on housing so indicator button contacts tooth on ring gear, and check ring gear backlash. Backlash should be .005-.008". If backlash greater than .008", loosen right hand adjusting nut one notch and tighten left hand nut one notch. If backlash less than .005", loosen left hand nut one notch and tighten right nut one notch. Check and adjust pinion setting as indicated below.

Pinion Setting–Coat ring gear teeth lightly with red lead or Prussian blue, then turn the pinion shaft several revolutions in both directions to establish a gear pattern on the ring gear. Examine pattern on the right gear teeth. If pinion depth is correct, the tooth pattern will be centered on the pitch line and toward toe of ring gear. If pattern is below pitch line on ring gear teeth, the pinion is too deep and it will be necessary to remove pinion and **increase** the shim thickness between pinion bearing and differential carrier housing. If pattern is above the pitch line, the pinion is too shallow and it will be necessary to **decrease** shim thickness in carrier housing. *NOTE*–Changing the pinion depth will make some change in backlash and it may be necessary to readjust the backlash (see above). Tighten bearing capscrews to 130-160 ft. lbs. Recheck backlash and install adjusting nut locks.

Thrust Pad Adjustment: Check bronze tip on thrust pad and replace if worn. Install thrust pad and tighten until pad contacts ring gear, then back off 30° to obtain a clearance of .005-.007". Tighten locknut.

Vacuum Cylinder: Inspection–Clean all metal parts with solvent and blow dry with air. Inspect diaphragm for loss of resiliency and punctures. Check spring of pushrod for breaks or distortion. Check mating surfaces of diaphragm housing and cover by placing the two parts in their assembled position and checking for deformation or burrs. Inspect piston rod outer surfaces for burrs as these can cause leaks at leather and felt seals.

Reassembly–Insert pushrod in piston rod and compress rod spring and install snap ring. Apply Permatex to ridges and around the center hole of diaphragm plates. Position diaphragm between the two plates and install plates and diaphragm on pushrod assembly. Install a new oil seal in diaphragm housing using Seal Installer J-968 (soak seal in oil prior to installation and coat outer radius with Permatex to assure a tight seal). Oil and install new leather and felt seals in diaphragm attaching flange. Insert pushrod assembly with attached diaphragm into housing. Align holes in diaphragm and housing and install housing cover.

Installati n–Install vacuum cylinder assembly on differential carrier housing with three bolts and lockwashers.

CHRYSLER, DE SOTO, DODGE "BARREL" TYPE HYPOID

Six, All Models with PowerFlite (1955)②

①—Pinion bearings adjusted by bearing adjuster washer between shoulder on pinion shaft and front bearing cone.

②—Pinion bearings adjusted by shims placed between bearing spacer and front bearing cone. No shoulder on pinion shaft.

③—Ring gear thrust pad and screw used on 1953 Cars with Torque Converter. Not used on cars equipped with PowerFlite.

►*DIFFERENTIAL PINION GEAR NOTE:* Two or four differential pinion gears used. Overhaul and adjustment are the same except where noted.

►*OTHER MODELS NOTE:* All other Chrysler, DeSoto & Dodge Models use "Cage Type" Hypoid. ***See "Chrysler, DeSoto, Dodge & Plymouth Cage Type" Rear Axle.***

►***DIFFERENTIAL CASE NOTE—"Screwed Type" and "Bolted Type" Differential carrier caps used. Different disassembly & reassembly procedures required for each type. See "Differential Case Disassembly" below.***

►***EARLY 1952 DE SOTO V-8 NOTE—First cars used "Screwed Barrel Type" differential case.***

►*1955 PINION NUT TIGHTENING CAUTION:* A convex (Belleville Lockwasher) is used on some models. It is important that this washer be installed with the convex side contacting the companion flange nut. Tighten pinion nut as follows when this washer used. 240 ft. lbs. min. (Chrysler Windsor), 250 ft. lbs. min. (Other Chrysler Models) 300-330 ft. lbs. (DeSoto Models).

DESCRIPTION: Hypoid gear, semi-floating type with either "Screwed" or "Bolted" barrel type differential case. Two different types of pinion shaft assemblies requiring different overhaul and adjustment procedures.

REMOVAL OF AXLE: ***See "Rear Axle" on Car Model pages.***

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: Remove rear wheels and hub and drum assembly using Tool C-845 (CAUTION—Do not strike end of axle shaft to loosen hub). Block brake pedal so it cannot be depressed and disconnect brake line at wheel cylinders. Remove rear axle drive shaft key and install sleeve Tool C-757 in axle bearing outer seal before removing brake support plate from axle housing. Remove shims from each end of axle housing and keep each set separate for reassembly. Remove axle shafts and bearings from housing using Tool C-499. Remove rear axle shaft inner oil seal.

Installation & Adjustment—Install axle shaft inner oil seal using Tool C-241. Insert axle shaft in housing making sure shaft and differential side gear splines are in alignment. Install axle shaft outer bearing (if removed) using Tool C-413. Install sleeve Tool C-757 in outer bearing oil seal before mounting brake support plate to axle housing to protect seal. Install brake support plate and tighten nuts to 30-35 ft. lbs. Connect brake tubes and bleed brakes. NOTE—If new axle shaft installed, it will be necessary to adjust the end play and center the axle. See Endplay Adjustment following.

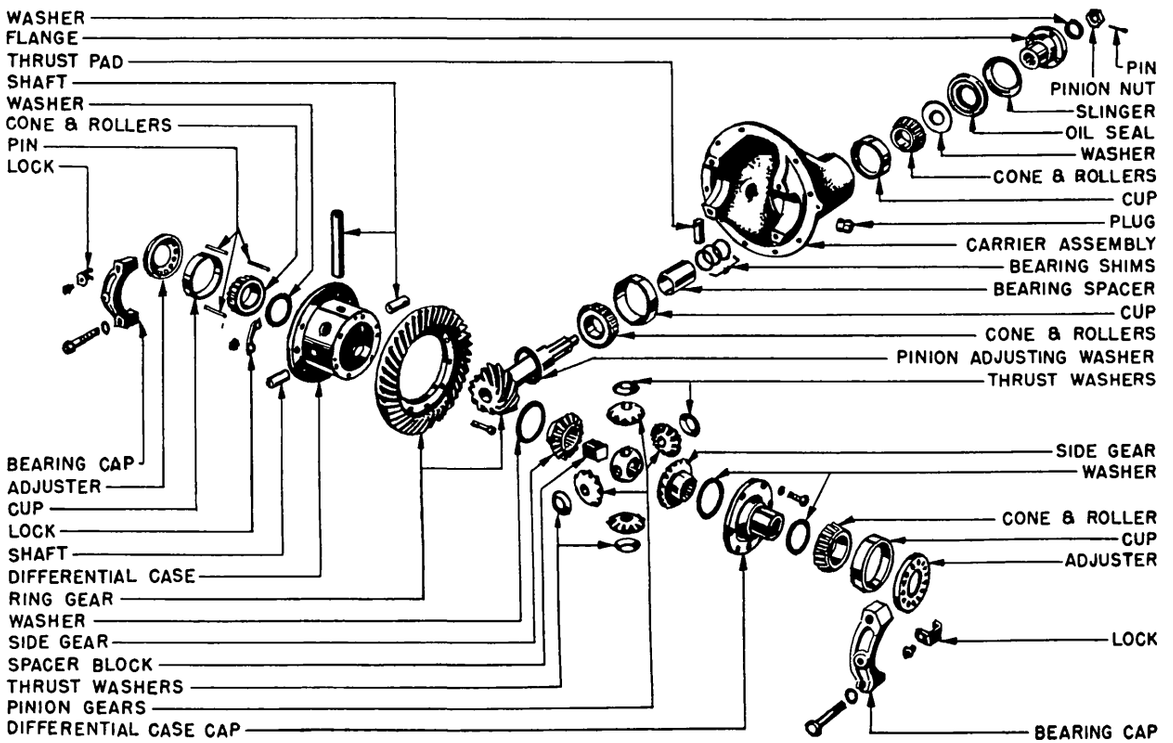
Endplay Adjustment—Remove wheel and hub and tighten brake backing plate securely. Rap each axle shaft to be sure bearings and cups are seated, then place a dial indicator on axle drive shaft and housing in such a way to measure endplay of shaft. Check the endplay by moving axle shaft in and out. If endplay is not between .003" to .008", remove brake support plate and add or remove shims as required.

►*CAUTION*—When making adjustment of endplay, equal thicknesses of shims should be removed or installed on both right and left sides of axle housing, so as to retain central position of axle shaft thrust block.

Centralizing Rear Axles (Initial Installation of New Axle Shaft)—Install left axle shaft and bearing cone assembly (without grease). Drive bearing cup in as far as it will go using Tool C-413 to prevent damage to axle housing. Rear axle thrust block will be removed as far to the right as possible. With left bearing cup remaining at its innermost position, lay a straightedge across end of axle housing. Measure distance from straightedge to bearing cup face, to nearest 1/64". One-eighth inch minus the above measurement gives the thickness of shims required at left end to center the thrust block, (it is best to use a shim about .020" less than that required to center thrust block). Remove the left axle shaft, grease the bearing and reinstall bearing and shaft. Using the correct thickness of shims as determined above, install the support plate. Do not drive bearing cup in all the way (as the brake backing plate, when it is drawn up tight will push the bearing cup into the correct position). Install the right axle shaft and bearing (bearing should be clean and dry). Using Tool C-413, drive bearing cup in as far as it will go, meanwhile rotating axle shafts to seat bearings, (Right bearing cup should protrude beyond housing end). Hold straightedge firmly across outer face of right bearing cup. Using a set of feeler gauges, measure accurately the distance between housing face and straightedge. This measurement gives thickness of shims that would give zero endplay if it were used. The shim thickness to be used is obtained by adding .003" to above measurement. If this gives a thickness that cannot be built up from existing shims, use the next larger shim combination. Remove the right axle shaft and grease the bearing and reinstall shaft and bearing and shim pack (as determined above), and complete the assembly.

C NTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE "BARREL" TYPE HYPOID (Cont.)



OVERHAUL: (Disassembly)—Mount carrier assembly in stand, then mark both differential bearing adjusters and caps to insure reinstallation in correct position. Remove adjusting nut locks, back off adjusting nuts, take out bearing cap screws, remove bearing caps, and lift differential assembly out of carrier. Remove drive pinion shaft nut, pull universal joint drive pinion flange, and remove pinion shaft through rear end of carrier. Use puller C-293-C to remove rear bearing from shaft.
NOTE—Front oil seal can be replaced without dismantling carrier.

Differential Disassembly (Bolted Barrel Type): Place differential case in large vise with jaw protectors in place. Bend down tabs and remove drive gear to differential case attaching nuts and bolts. Tap drive gear off case with a fibre hammer. Mount case, bearings and cup assembly in carrier and check drive gear flange run-out which should not exceed .003". Remove case from carrier and remove differential case bearings with puller C-293 and No. 18 plates. Remove the six bolts attaching case cap to case, then remove three differential pinion shaft lock pins by driving them out of case. Drive long pinion shaft out of case with a brass drift and hammer, and remove axle shaft thrust block. Drive the short pinion shafts out of case and remove pinion shaft block. Remove pinion gears, side gears and thrust washers.

Differential Disassembly (Screwed Barrel Type): Mount differential case drive gear flange in large vise with jaw protectors, then remove differential case bearings with puller DD-914-89. Remove the differential case cap locking pins by center punching and drilling. Remove shell of pin in hole with punch. Heat outside of case with a torch DO NOT HEAT CAP, to a temperature of **not more than 360°-400°F.** (Check heat by means of a piece of soft solder, which will just start to melt when case is hot enough). Unscrew cap with special wrench DD-921 (start cover by jarring wrench handle with heavy hammer blow). Cool parts in oil and proceed with disassembly. Drive out the pinion shaft retaining pin, and with a hammer and drift, drive the long pinion shaft from case, and remove thrust block. Now drive the short pinion shafts from case and lift out pinion shaft block. Remove differential pinion gears, side gears and thrust washers from bottom of case.

►***DIFFERENTIAL CASE REASSEMBLY NOTE—Assembly of "Bolted Type" differential is identical to assembly of "Screwed Type," except that heating the case for cap installation is not necessary.***

Differential Case Reassembly (Bolted & Screwed Barrel Type): Place thrust washer over hub of differential side gear and lay in position in case. Line up the locking pin hole in long pinion shaft, with the hole in differential pinion boss (opposite boss has no pinion hole) and drive the pinion shaft in until it protrudes about 1/16" on inside of case. Place a pinion gear thrust washer on pinion so the side with indents faces pinion, then install pinion gear and washer on end of shaft that protrudes. Tap shaft and hold pinion until end of shaft is even with edge of pinion. Insert the pinion shaft block with punch marked sides facing the short pinion shaft holes and the side marked "1" facing up. Install thrust block and pinion shaft block. Install the opposite pinion gear and thrust washer, then drive shaft into final position. Drive one of the short pinion shafts into either of remaining holes until shaft protrudes 1/16" on inside of case. (Make sure lock pin holes line up). Install pinion gear and thrust washer and continue to drive until shaft enters hole in pinion shaft block. Install other short pinion shaft, washer and gear in same manner. Lock pinion shafts in place by installing three new locking pins in the holes and peen over.
("Screwed Barrel Type")—Clamp complete assembly in vise and heat outside surface of threaded portion of case with a torch flame as indicated in disassembly procedure. Dip threaded portion of cap in gear oil, and then assemble thrust washer and side gear in cap and screw into differential case with wrench DD-921. Tighten securely with blunt drift and hammer. Drive three new case cap lock pins 1/16" below surface of case and peen metal of case over pins with a ball end punch.
("Bolted Barrel Type")—Assemble a thrust washer and remaining side gear in cap. Using two of the attaching bolts as guides, position differential cap on case, then tap into place using a soft hammer. Tighten cap retaining bolts to 35-40 ft. lbs. Install ring gear on flange, then place locking tabs in position and install gear retaining nuts. Tighten nuts to 35-40 ft. lbs., and bend up tabs to lock nuts in position.

CHRYSLER, DE SOTO, DODGE "BOLTED TYPE" HYPOID

Pinion Bearing Preload: Preload check is made with Tool C-758-D which replaces pinion gear and shaft in housing when making check. Pinion adjusting shims or spacers are placed as indicated in model application above.

Pinion Bearing Preload

Car Model	In. Lbs.
1946-48 Chrysler 8, Crown Imperial	10-15

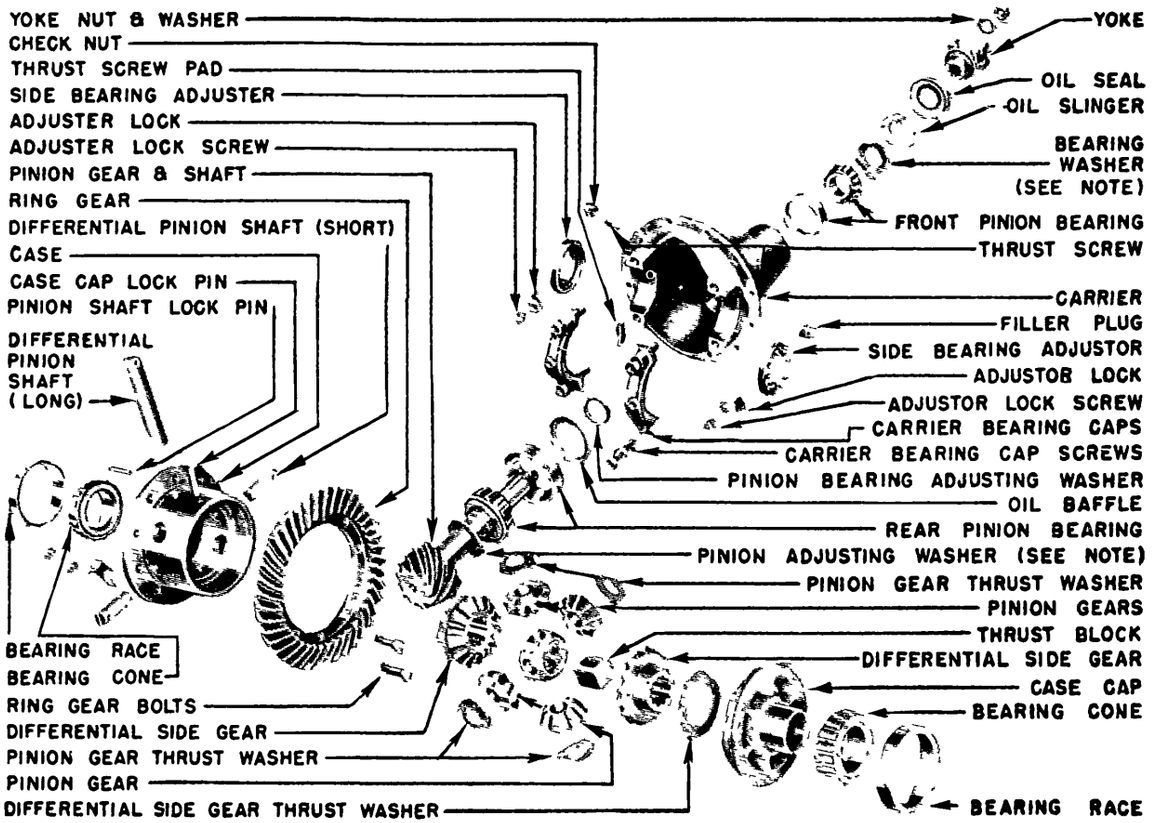
1955 Dodge 6 & V8, Auto. Trans.	20-30

Pinion Preload Check (Pinions With Wide Spacer and Shim Pack)—Adjust pinion bearing preload BEFORE pinion gear setting is made. Coat drive pinion with hypoid lubricant, and assemble the

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE "BARREL" TYPE HYPOID (Cont.)

drive pinion shaft rear bearing on main body of Tool C-758-D. Slide sleeve SP-1730, drive pinion bearing spacer and bearing adjusting shims over tool and insert the assembly into carrier. Slide front pinion bearing over tool and down into position in bearing cup. Slide compression sleeve SP-535 and centralizing washer over tool and down into position and install the compression nut. Tighten tool nut to torque indicated in "Tightening Torques" table below. Turn tool with a speed wrench to seat bearings, then check preload with an inch-pound torque wrench. Readings should be as indicated in table above If adjustment does not conform to above readings, increase size of shim pack to **decrease** reading; decrease size of shim pack to **increase** reading. After correct preload setting has been obtained, leave tool in place for pinion setting.



Pinion Preload Check (Pinions With Single Narrow Spacer and Shoulder on Pinion Shaft)—*Pinion bearing preload must be checked AFTER pinion gear setting is made.* Install pinion shaft adjusting washer and tool spacer SP-1371 over main body of Tool C-758-D with pinion shaft adjusting washer away from gear end of tool, then install pinion shaft rear bearing, and tool spacer SP-1370 and the pinion bearing adjusting spacer (that was removed from axle at disassembly). Insert assembly into carrier housing, then install front bearing onto shaft and into position in cup. Install compression spacer, centralizing washer and compression nut. Tighten nut to the torque indicated in "Tightening Torques" table below. Turn tool with speed wrench to seat bearings, then check bearing preload with an inch-pound wrench. Readings should be as indicated in table above. Increase size of spacer if reading is greater than upper limit, or decrease size of spacer if reading is less than lower limit. When reading is correct, remove tool and reassemble bearings and spacers to pinion shaft and install in housing.

Pinion Bearing Spacers—Spacers are available in sizes from .175" to .203" in steps of .002".

Pinion Bearing Carrier Assembly—After correct shims or spacer has been selected, disassemble Tool C-758-D and install pinion shaft adjusting spacer over pinion shaft and down against the machined surface of drive pinion. Install drive pinion rear bearing on pinion shaft and press it into place with Tool C-996. Slide bearing spacer and shim pack into position against rear bearing (if pinion shaft has a shoulder and narrow type spacer, install this narrow type spacer which was selected for correct bearing preload) Insert assembly into carrier housing (lubricate all parts with hypoid lubricant). Slide front bearing over pinion shaft and into position in bearing cup, then install bearing oil slinger. Install new seal over pinion shaft and drive into position using Tool C-359. Install companion flange on shaft and install washer and nut. Tighten nut to torque indicated in "Tightening Torques" table below.

Pinion Nut Tightening Torque

A.T.—Automatic Transmission.

Pinion Setting: (Without Tool C-758-D)—Pinions are marked "0" (standard) or "+" or "—" followed by figure (1 to 4 indicating necessary correction for other than standard "0" pinions). When installing new pinion of same marking as old pinion, use same spacer thickness for this new pinion. If new pinion marked "+" or "—" used to replace "0" standard pinion, use thinner washer (+ pinion), thicker washer (— pinion) than the washer used with the original pinion. The difference in thickness from the original washer should be equal in thousandths to the figure following the + or — mark on the pinion. Pinion position is controlled by spacer, installed on shaft between pinion and rear bearing. Pinion must be removed from carrier housing and bearings removed from shaft to change washer (or shims as used on some models) to correct pinion setting and gear mesh. See Ring & Pinion Gear Adjustment below also.

Washer Note—Pinion adjusting washers furnished in following thicknesses: .088", .090", .092", .094". Shims (when used) furnished .010", .0125", .015", .018" thick.

►*PINION SETTING NOTE*—Install Tool C-758-D as follows before setting pinion.

Chrysler 6 & Dodge V8 With Torque Converter—Install tool in same manner as that used for Pinion Bearing Preload (See above).

Other Models—Assemble spacer SP-1371 to main section of Tool C-758-D, then install spacer SP-1370 and slide pinion rear bearing over spacer SP-1370 and up against spacer SP-1371. Insert tool as assembled into carrier housing and install front bearing over tool shaft and into position in bearing cup. Tighten tool compression nut so torque required to

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE "BARREL" TYPE HYPOID (Cont.)

rotate tool assembly is as indicated in Pinion Bearing Preload table above, with bearing lubricated with hypoid gear oil

Pinion Setting (With Tool C-758-D): Fasten Gauge Block SP-528 to rear end of main tool body, and place Arbor SP-561 in differential carrier bearing supports Install bearing caps and bolts and tighten bolts to 10 ft lbs (NOTE—Remove all burrs and foreign material in bearing bores before installing arbor) Select a pinion washer that will just pass between arbor and gauge block (For an example if a 090" can be inserted but a 092" cannot be forced between the two surfaces by hand, the 90" washer should be used even though it feels loose) Check pinion shaft end as it may indicate the amount that should be added or subtracted from the washer in the above check (If mark on shaft indicated a +2, a 002" thinner washer should be used for final assembly If a —2 were indicated, then 002" should be added to washer initially selected) When correct washer has been selected for the drive pinion, disassemble tool and proceed with pinion shaft installation (See Pinion Bearing Carrier Assembly above)

Spacer Washer Note—Spacers furnished in sizes from 084" to 100" thick, in steps of 002"

Differential Case Disassembly: Remove right hand differential side bearing roller and cone assembly (use Puller C-293-C). Center punch and drill out the cap locking pins (pins on rim of differential case which lock cap in place), remove remaining pieces of pins with punch Mount the case in a vise and carefully heat the case by playing a torch flame around the outside (Do not heat the cap) to a temperature of not more than 360-400°F. NOTE—Check heat by means of a piece of ordinary soft solder, when case is hot enough, solder will just start to melt. Unscrew cap with special wrench DD-921 (start cover by jarring wrench handle with heavy hammer blow) or use a blunt drift and heavy hammer Cool parts in oil and proceed with disassembly.

Differential Gear Removal (from case)—Remove the differential pinion shaft locking pin (three lock pins on 1951 and later) by driving from case with hammer and punch Push differential pinion shaft out of case (on 1951 and later, first drive the long pinion shaft out of case then drive out the two short pinion shafts Lift out the center block, pinions and thrust washers Then remove the differential side gear and thrust washer from bottom of case). The gears, thrust washers and axle shaft thrust block will then be loose and fall out of case.

Differential Gear Assembly (into case): 1950 & Earlier

1. Reverse removal procedure, note the following: Coat parts with differential lubricant to help hold them in place during assembly of thrust block and differential pinion shaft Heat case as outlined for removal and install cap, tightening it with DD-921 if available or with a drift punch and hammer. Drill new ¼" holes through cap and install new locking pins.

1951 and Later—If new differential side gears are to be installed, place a new thrust washer over hub of gear and lay gear in differential case.

2. Line up locking pin hole in long pinion shaft with hole in differential case pinion boss (opposite boss has no pinion hole) and drive pinion shaft in until it protrudes about 1/16" on inside of case

3. Place pinion thrust washer on pinion so that the side with indents faces pinion and install pinion Insert pinion shaft block with punch marked sides facing short shaft holes and side marked (1) facing up, and continue driving long shaft through block Install the opposite pinion and thrust washer and drive shaft into final position.

4. Drive one of the short pinion shafts into either of the remaining holes until shaft protrudes 1/16" on inside of case Be sure lock pins line up. Then install thrust washer and gear and continue driving short shaft until shaft enters the hole in pinion shaft block Install the other short shaft, washer and gear in same manner.

5. Lock the three pinion shafts to the case by installing three new locking pins in the holes and peen over

6. Clamp the assembly by the drive gear flange between copper jaws of a heavy vice and heat the outside surface of the threaded portion of case with a torch flame as outlined in disassembly procedure

7. Dip the threaded portion of cap in gear oil, assemble the thrust washer and differential side gear in the cap and screw the cap into differential case with Wrench DD-921 Then, tighten securely in position with blunt punch and heavy hammer.

8. Drive in three new differential case cap lock pins 1/16" below surface of case and peen surface of case over the pins with a ball end punch Blow air through the assembly to remove all drill cuttings.

Differential Bearing Preload & Backlash Adjustment: When installing differential carrier assembly, turn adjusting nuts up to marks made before disassembly, then check bearing adjustment as follows Check drive gear for runout Gear should be true within 004" Screw out bearing adjusting nut at back face of drive gear, and screw in the opposite nut until ample backlash is obtained Tighten lower cap bolts to 90 ft lbs, leaving the top bolts fairly loose Screw out adjusting nut on tooth side of drive gear, until nut clears cup Screw in opposite adjusting nut until there is only a little backlash Turn drive gear a few times by hand to seat bearings With a dial indicator, find the point of least backlash on drive gear at 90° intervals At the point of least backlash, screw in adjusting nut at back face of drive gear until 001" shows on indicator Turn in adjusting nut on tooth side until indicator shows 006" Lock adjusting nuts in place and tighten both top cap bolts to 90 ft lbs

Ring Gear Thrust Pad Adjustment: Clearance between thrust pad and rear face of ring gear should be 006-008" To adjust, loosen locknut on left side of carrier housing (nut and screw are tack welded together) Turn stud up finger tight, and back off so there is 006-008" clearance between thrust pad and drive gear

Six, All Models Exc. 1951-54 Estate Wagon & 8 Pass. Models (1946-54)

DODGE MODELS

Six & Eight, All Models Exc. 1953-55 V8 & 1955 Six with Auto. Trans. (1946-55)

PLYMOUTH MODELS

Six & Eight, All Models (1946-55)

▷OTHER MODELS NOTE—All other Chrysler, DeSoto, Dodge, Plymouth Models use "Barrel Type" Hypoid *See "Chrysler, DeSoto, Dodge Barrel Type" Rear Axle, preceding.*

▷CHANGES, CAUTIONS, CORRECTIONS

▷RING & PINION GEAR CAUTION: Both "Formate" and "Generated" type gears used. Both types of gears are interchangeable in matched sets only. Gears can be identified by part number (stamped on all gears) or by word "FORMATE" stamped on all formate gears and pinions. Gears and pinions of "Generated" type have part number only.

▷*CAUTION—Ring and pinion gears should be installed as matched sets and both gears must be of same type (Formate or Generated).*

DESCRIPTION: Hypoid gear, semi-floating type with Hotchkiss Drive

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: To remove shaft, remove wheel, shaft nut, hub and brake drum assembly (use special hub puller C-675), disconnect brake line at wheel cylinder, take out stud nuts and remove oil seal and backing plate, remove and save wheel bearing adjusting shims, use puller C-499 to remove axle shaft and bearing assembly To remove bearing from shaft, use puller C-293-C When replacing shaft, check wheel bearing adjustment (endplay) as directed below

Wheel Bearing Oil Seal—Use special seal puller C-358 or C-748 to remove oil seal from housing. NOTE—If new oil seals installed, soak in thin oil for 30 minutes, roll seal with smooth bar before installing and use special tool C-201 (6 Cyl. cars), C-241 (8 Cyl. cars) to install seals.

Axle Shaft Endplay—Should be .003-.008". When dismantling axle, make certain that shims installed between backing plate and axle housing flange are saved and replaced when axle reassembled. If new shaft installed, adjust shim thickness for correct endplay as noted above (adjust equally at both wheels) Shims furnished in thicknesses of 005", 010", 0125", 015', 030'

OVERHAUL: Disassembly. With differential carrier out of axle housing, mark both bearing adjuster nuts and bearing caps so that they can be installed in correct position and approximately right adjustment, remove bearing cap screws, lift out differential and ring gear assembly. To remove pinion, take off nut on end of pinion shaft, use tool C-452 to pull pinion flange. Pull pinion out through rear end of carrier housing Use special puller C-293-C to remove bearing from pinion shaft Reassemble by reversing disassembly procedures Use tool C-496 to install pinion shaft flange

Pinion Shaft Oil Seal. Can be removed and installed without removing differential bearing assembly or pinion. To remove, take off nut on end of pinion shaft, remove rear universal yoke flange, use

CONTINUED ON NEXT PAGE

CHRYSLER, DE SOTO, DODGE, PLYMOUTH "CAGE" TYPE HYPOID (Continued)

puller C-358 or C-748 to remove oil seal. Soak new oil seals in thin engine oil for 30 minutes (seal leather must be soft and pliable), **use special tool C-359 to install oil seal in carrier housing.**

Pinion Bearing Preload: 15-25 in. lbs. (1955 Plymouth 20-30 in. lbs.) turning torque measured **without oil seal** but with pinion completely assembled in carrier.

Pinion Bearing Adjustment (With Dial Indicator): Completely assemble pinion in carrier housing but do not install oil seal, then check pinion shaft **endplay with dial indicator. If no endplay, take off pinion shaft nut, pull oil seal (see below), remove front bearing, add shims to give positive endplay reading, reassemble and check endplay (universal yoke flange must be in place and nut on shaft tight). Remove shims equal to observed endplay** plus .002" shim thickness which will give correct bearing draw or pre-load. Check pre-load with torque wrench noting turning torque required to rotate shaft which should be 15-25 in. lbs. (20-30 in. lbs. on 1955 Plymouth). After adjustment completed and oil seal has been installed, tighten companion flange nut to 175 ft. lbs. (1946-50 Chrysler & DeSoto), 180-320 ft. lbs. (1946-54 Plymouth & 1951-54 Chrysler & DeSoto), 250-280 ft. lbs. (1955 Plymouth), 180-200 ft. lbs. (Dodge).

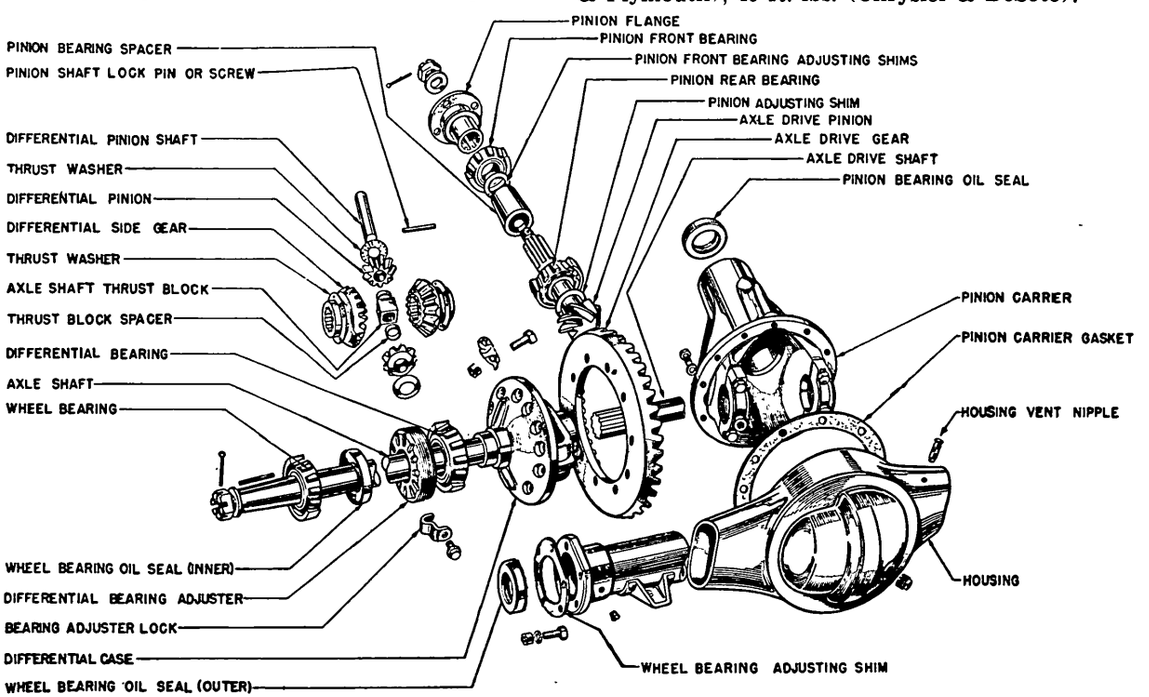
NOTE—These shims furnished in thicknesses of .010", .0125", .015", .018".

Pinion Bearing Pre-load Check (With Tool C-758-D): With bearing cups installed in carrier housing, slide rear bearing and spacer over main body of C-758-D tool and insert in carrier. Install adjusting shims and front bearing on end of tool, install compression sleeve, centralizing washer, and compression nut over main body and tighten to 180-320 ft. lbs. (use holding tool C-784 and torque wrench). Spin main body in carrier to seat bearings. Then use in. lb-reading torque wrench to turn main body and note wrench reading which should be 15-25 in. lbs. Adjust by adding or removing shims until correct reading secured. **Adjust Pinion Setting (following) before removing tool.**

Pinion Setting: Pinions marked "0" (standard) or "+" or "—" followed by figure (1 to 4) indicating necessary correction for other than standard "0" pinions. When installing new pinion of same marking as old pinion, use same spacer thickness for this new pinion. If new pinion marked "+" or "—" used to replace "0" standard pinion, use thinner washer (+ pinion), thicker washer (— pinion) than the washer used with the original pinion. The difference in thickness from the original washer should be equal in thousandths to the figure following the + or — mark on the pinion. Pinion position is controlled by spacer, installed on shaft between pinion and rear bearing. **Pinion must be removed from carrier housing and bearings removed from shaft to change** washer (or shims as used on some models) **to correct pinion setting and gear mesh. See Ring & Pinion Gear Adjustment below also.**

Washer Note—Pinion adjusting washers furnished .084" to .100" thick in .002" steps. Shims (when used) furnished .010", .0125", .015", .018" thick.

Pinion Setting (With Tool C-758-D)—After checking pinion bearing pre-load (above) and **without removing tool,** place gauge block on top of tool body and tighten in place (gauge block takes place of pinion). Assemble cross bore gauge bar in carrier in place of carrier assembly, tighten adjusting nut capscrews to hold bar in place. Select spacer washer equal in thickness to clearance between gauge block and gauge bar. This is correct thickness for standard pinion (see Pinion Setting data above). Install this spacer washer on pinion shaft (or correct spacer thickness in accordance with pinion marking) when installing pinion in carrier.



Differential Gear Assembly: The differential pinion gear shaft **retained by pin or lockscrew. Clearance between differential side gears and pinions should be .004-.012" (controlled by thrust washer in back of each side gear). When assembling differential gears, make certain that thrust washer installed in back of each differential pinion and side gear, thrust block installed on pinion shaft at center, and that spacer installed between thrust block and each differential pinion. CAUTION—Thrust block must be properly centered in differential carrier. This block transmits end thrust from one axle shaft to the other.**

Differential Bearing Adjustment:—Bearings **should be just tight enough to cause slight drag when ring gear revolved by hand (assembly must not spin). Mark adjusting nuts and bearing caps before dismantling differential assembly to allow replacement in correct position. When installing assembly, tighten adjusting nuts with sufficient force to seat bearing cups solidly against shoulder in bore, back off right hand nut, tighten left hand nut until ring gear has slight backlash, turn gear several rotations to seat bearings, check backlash with dial indicator. At point of minimum backlash (check at four points 90° apart), turn left hand adjusting nut in or out until backlash is exactly .001", then turn right hand adjusting nut in until backlash shown on dial indicator has increased to exactly .006". Tighten adjusting nut capscrews and install adjusting nut locks. This procedure will provide correct bearing pre-load and correct ring and pinion gear backlash in one operation.** Check gear mesh by painting gears.

Ring & Pinion Gear Adjustment: Paint gears to check mesh. Backlash should be .006-.008" (Chrysler & DeSoto), .006-.010" (Dodge & Plymouth). Adjusted by backing off one differential bearing adjusting nut and tightening opposite nut equally. See Pinion Setting and Differential Bearing Adjustment above.

Ring Gear Backlash Adjustment. Check with dial indicator. To adjust, back off one differential bearing adjusting nut, tighten opposite nut equally. Check differential bearing adjustment.

Ring Gear Replacement:—Ring gear is press fit on differential case and is held in place by bolts or by capscrews. Tighten all evenly to 35-40 ft. lbs. (Dodge & Plymouth), 40 ft. lbs. (Chrysler & DeSoto).

CHRYSLER, DE SOTO, DODGE, PLYMOUTH "CAGE TYPE" HYPOID

1941-48 FORD & MERCURY

Ford, Passenger Car Models (1941-48)
Ford, Half-Ton Truck Models (1941-47)
Mercury, All Models (1941-48)

▷COMM'L AXLE NOTE (1942 & Later): The rear axles on these models are similar to passenger car axles, except that Hotchkiss Drive is used. Pinion assembly is retained by a Pinion Bearing Retainer and Pinion Grease Retainer Support bolted on front face of pinion housing (in place of torque tube) and a rear universal joint yoke is bolted directly on the end of the pinion shaft. These axles serviced in same manner as passenger car types except that data on torque tube should be disregarded.

DESCRIPTION: Spiral bevel gear, ¾ floating type with torque tube drive & straddle mounted pinion. Pinion mounted on double roller bearing (straddle mounted with additional roller bearing behind pinion).

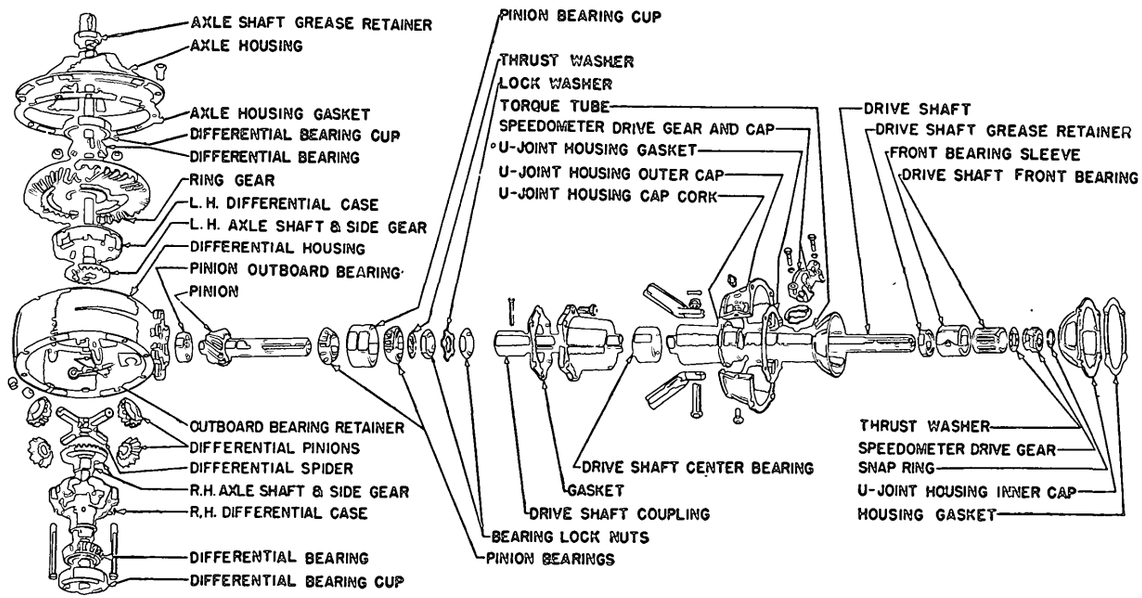
REMOVAL OF AXLE: *See "Rear Axle" on car model page.*

AXLE SHAFT REPLACEMENT: Remove axle shaft from inner end after axle dismantled and differential case bolts removed (side gears integral with shafts). When installing axles see that free travel or play at wheel keyway does not exceed .010" or endplay exceed .015". If play excessive, check differential gears for wear (pinion clearance .005" maximum).

PROPELLER SHAFT: Propeller shaft is part of rear axle assembly (pinned to pinion shaft). See overhaul data below. Propeller shaft bearings in torque tube are serviced as follows:

Propeller Shaft Forward Bearing:—In forward end of torque tube behind speedometer drive gear. Two types used (use B-4645-A roller assembly with split sleeve, 68-4645 with small rollers with solid sleeve). Use special puller SV-245 to remove solid sleeve from torque tube. Install new grease retainer (use tool A-310) with sharp edge of leather toward universal joint.

Propeller Shaft Center Bearing:—In torque tube at center. On types with solid propeller shaft, front bearing sleeve must be removed before center bearing can be removed with SV-186 tool (see above).



OVERHAUL: Disassembly. Remove speedometer driven gear assembly. Remove snap ring on forward end of propeller shaft, withdraw speedometer drive gear and thrust washer. Take out flange mounting screws at rear of torque tube, withdraw propeller shaft from tube toward rear. Drive out rivet in coupling, disconnect propeller shaft from pinion. Use AATA-1 driver to remove pinion assembly from housing, BV-92 puller to remove bearings.

Pinion Bearing Assembly:—Assemble bearings on pinion shaft (see illustration), tighten bearing locknuts so that bearing cup turns on cones with heavy drag. Heat housing (use approved heater or immerse housing neck in boiling water or hot oil for 1-2 minutes), install outboard bearing (use BV-94 driver), then with housing still hot install pinion assembly making certain that bearing cup is against shoulder in housing. Check pinion bearing adjustment only after installed in housing.

Pinion Bearing Adjustment:—Use approved gauge ABV-129 to check bearing adjustment. The setting (torque required to turn pinion) should be 12-17 in.lbs. To adjust, tighten pinion bearing nut until correct gauge reading secured (check only after pinion assembly installed in axle housing), then tighten locknut securely and turn lockwasher ears over on nuts to prevent nuts loosening in service.

Differential Bearing Adjustment:—Assemble axle housings with gasket thickness of .008-.010" between right and left hand axle housing and pinion housing. Check bearing adjustment by rotating both axle shafts simultaneously (rotating one shaft will not turn differential assembly). Differential assembly should turn with a heavy drag. If clearance too great, replace gasket between right hand axle housing and pinion housing with one thinner gasket (B-4035-B) .004" thick. Check backlash.

Ring & Pinion Gear Backlash: Use a dial indicator to show pinion gear shaft movement with ring gear stationary. Backlash .012" max. (Ford), .010" max. (Lincoln-Mercury). To adjust, increase or decrease maximum. Adjust by increasing or decreasing thickness of gasket between left hand axle housing and pinion housing. Total gasket thickness must not be changed in order not to disturb bearing adjustment (increase or decrease right hand gasket thickness equally).

FORD, LINCOLN-ZEPHYR, MERCURY (PASS. CAR) SPIRAL BEVEL GEAR AXLE

LINCOLN (ZEPHYR) HYPOID

Zephyr, Cont'l, & Custom Models (1941-48)

DESCRIPTION: Hypoid gear, ¾-floating, with torque tube drive. Same design as used on previous model (see Ford, Lincoln, Mercury Rear Axle) except for pinion mounting as follows:

Pinion Assembly:—Pinion integral with shaft and mounted on taper roller bearings. Bearing cups seated directly against shoulders in housing. Bearing cones positioned on shaft by spacer

Replacement Exchange Axle Assemblies—Assemblies consisting of differential housing (axle housing center section) with pinion gear installed (and set up for correct bearing adjustment and pinion gear mesh), and mated ring gear are furnished for all models as Part No. 86H-4020 (except 1942 models without Liquamatic Drive), No. 26H-4020 (1942 models without Liquamatic Drive only).

REMOVAL OF AXLE: *See "Rear Axle" on car model page.*

OVERHAUL: Manufacturer recommends that Axle Assembly (Differential housing with Pinion installed) not be dismantled and should be serviced by Axle Assembly Exchange (Assembly furnished with Pinion installed, bearings adjusted, and set for marked backlash with mated Ring Gear).

Differential Bearing & Ring Gear Backlash Adjustment—Gaskets for installation between differential housing and right and left axle housings furnished in three thicknesses as follows: .008-.010" (86H-4035-A), .004-.006" (86H-4035-B), .013-.018" (86H-4035-C). Normal gasket thickness (for correct backlash and differential bearing adjustment) is .005-.008" at each side of differential housing. Vary thickness at left hand housing to adjust backlash (keep total thickness for both sides same to avoid disturbing differential bearing adjustment), vary thickness at right hand side to adjust differential bearings (without changing backlash).
Ring Gear Backlash—Should be .002-.004". Ring gears marked with etched figure indicating correct clearance for each ring and pinion gear set.

FORD, LINCOLN, MERCURY "INTEGRAL CARRIER TYPE" HYPOID

Ford, Station Wagon (1949-55)
Ford, Sedan Delivery (1952-55)
Ford, ½-Ton, F-1, F-100 Trucks (1948-55)
Ford, F-250 Trucks (Late 1955)
Ford, P-350 Parcel Delivery (Late 1955)
Ford, Thunderbird & Interceptor (1955)
Lincoln, All Models (1949-55)
Mercury, Pass. Cars (1949-51 & 1955)
Mercury, Station Wagon (1949-55)

NOTE—See "Ford & Mercury Hypoid (Separate Carrier)" for other Ford & Mercury applications.

►CHANGES, CAUTIONS, CORRECTIONS

►**1951-52 FORD STATION WAGON & F-1 TRUCK DIFFERENTIAL GEAR & PINION PRODUCTION CHANGE (Used for Short Time Only):** Gears and pinions used in production between approximately Dec. 26, 1951 and March 1, 1952 differed from previous and later types by having a special gear tooth chordal thickness (gear tooth thickness increased .003", pinion tooth thickness decreased .003"). After March 1, 1952, the previous type gears were again used. GEAR & PINION TYPES MUST NOT BE INTERCHANGED (will result in binding or excessive back lash depending on combination). *CAUTION—These gear and pinion types must be used together. If necessary to replace gears or pinions in these axles (Dec. 1951 to Mar. 1952), install complete set of gears and pinions from service stock.*

►**1950 REAR AXLE PRODUCTION CHANGE (Except Lincoln & Cosmopolitan)**—Entered production (Mercury) June 1950, (Ford F-1 Truck) Late 1950, (Ford Station Wagon) Start of production 1951. Ring gear diameter changed from 9¼" to 8½". Bolt circle changed from 5⅝" to 6⅝". Axle ratios remain approximately the same although number of teeth on ring gear and pinion have been decreased. Housing has also been changed. Parts are not interchangeable with previous axle.

►**1949 RING GEAR MOUNTING BOLT PRODUCTION CHANGE:** New type bolts No. 350634-S, used to mount ring gear on differential case, beginning Jan. 1949. When installing new parts on axles prior to this date, change ring gear bolts to new type (can be done by working through inspection cover hole and changing two bolts at a time).

►*MOUNTING BOLT IDENTIFICATION NOTE*—New type bolts (above) can be identified by following marks on head: "A" or "F" in circle, "H" (plain letter), "C" with radiating lines, or radiating lines without a letter. All other marked bolts are old type.

►**REAR AXLE IDENTIFICATION NOTE**—Metal tag attached to one axle housing cover screw stamped with number of ring gear and pinion teeth.

►*CAUTION—Re-install identification tag when housing cover replaced.*

►**1955 FORD REAR AXLE PRODUCTION CHANGES (Applies to all previous "Integral Carrier" type rear axles):** Lock straps not required on ring gear-to-case capscrews (torque to 40-50 ft. lbs.). Differential bearings capscrew lockwashers no longer used (torque to 70-90 ft. lbs.). Pinion shaft oil slinger no longer used.

DECRIPTION: Semi-floating, hypoid gear, Hotchkiss drive type. **This axle does not have a s parate differential carrier assembly.**

AXLE SHAFT REPLACEMENT: Remove wheel, remove brake drum by taking out tinnerman nuts securing drum to axle flange. Rotate axle shaft until hole in shaft flange lines up with one of four bolts mounting backing plate and bearing retainer on housing, remove all bolts. Use Tool 4235A (sliding hammer) to remove axle shaft and bearing assembly from housing. Use care not to dislodge the brake backing plate or damage the oil seal in the housing. *NOTE—If oil seal being replaced, disconnect brake tube from backing plate. Plate can be laid on floor without disconnecting brake cable.*

Wheel Bearing Replacement: Cut bearing retainer ring with chisel, slide ring off shaft, use Tool 4234 to press bearing off shaft in arbor press. When cleaning parts, DO NOT wash pre-lubricated wheel bearing with solvents (will remove lubricant) Press bearing on shaft, using Tool 4234, then press on new wheel bearing retainer ring. (CAUTION—do not attempt to press bearing and retainer on in one operation).

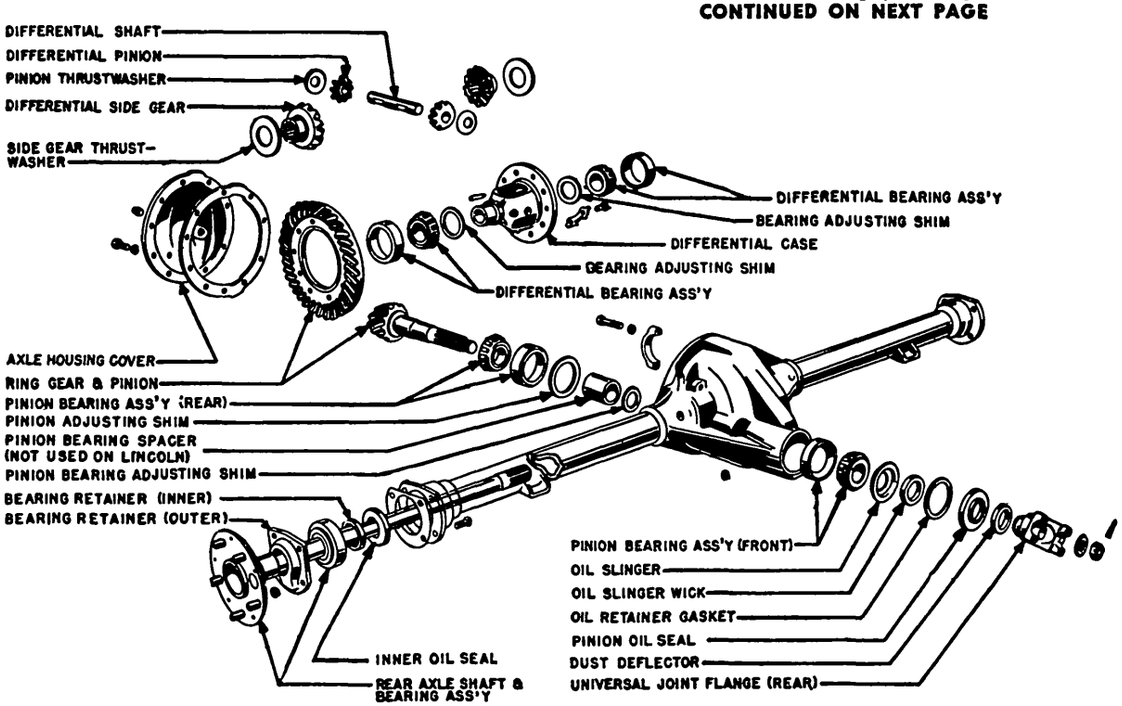
Oil Seal Replacement: Use Tool 4235-B to install seal in housing. Use great care to keep seal square with housing while installing. Seat seal **lightly** against shoulder in housing. Apply cup grease to seal surface before installing axle shaft.

Axle Shaft Installation: Use care not to damage oil seal when installing axle shaft. Tighten bearing retainer and backing plate bolts to 30-35 ft. lbs. Install brake drum and secure to axle flange with tinnerman nuts. CAUTION—If brake tube removed, reconnect and bleed brakes.

Drive Pinion Oil Seal Replacement: (Without removing Differential Carrier): Disconnect drive shaft at rear universal joint. Mark position of universal joint flange, nut & shaft with a punch, to insure installing at the same position. Remove pinion shaft nut and pull flange with Tool 4858-Q. Install an oil seal puller and pull seal from housing. To install, position seal in housing and drive into place with Tool 4676. Install flange on pinion shaft with marks in line, and install pinion shaft nut and tighten until it is tight on shaft with marks on flange, shaft, and nut aligned.

REMOVAL OF AXLE: *See "Rear Axle" on Car Model page.*

REAR AXLE (Disassembly): Remove axle shafts (see Axle Shaft Removal above).



1)—Remove cover assembly and gasket and install axle housing spreader Tool 4000-A and spread axle housing not more than .015".

►*CAUTION—When using axl spreader tool to spread axle housing, do not spread more than .015" which is necessary for differential removal, and remove spreader immediately to avoid housing taking on permanent "set."*

2)—Mark differential side bearing caps to insure correct reassembly (NOTE—Lincoln bearing caps are marked at factory with a letter or a figure stamped on cap, and on the housing at a point adjacent to the cap. Left side marks are horizontal and right side marks are vertical). Remove bearing caps and pry differential assembly loose from housing and lift assembly out.

3)—Remove nut from pinion shaft, holding the flange with Tool 4851-C. Remove flange with Tool 4858-D (Lincoln & Mercury), 4858-Q (Ford). Drive

CONTINUED ON NEXT PAGE

LINCOLN, MERCURY, FORD "INTEGRAL CARRIER" HYPOID AXLE

FORD, LINCOLN, MERCURY "INTEGRAL CARRIER" TYPE (Continued)

pinion toward rear of housing with Tool 4201, and withdraw pinion and rear bearing cone and roller assembly.
4)—Remove oil seal from front end of housing with Tool 1175-B. Lift out pinion shaft ring gasket, wick, slinger and front bearing cone and roller assembly.
5)—Remove pinion front bearing cup with Tool 4628-B, and rear bearing cup with Tool 4628-D.
CAUTION—Do not loose shims located in housing back of rear bearing cup. If pinion is not to be replaced, these shims will be installed at reassembly.

Differential Disassembly: Remove differential side bearings with Tool 4221-C, and remove shims located between bearings and carrier (Note the number and thickness of shims behind each bearing as these shims must be replaced unless new parts are to be installed). Pry ring gear bolt locking tabs away from bolt heads and remove capscrews and ring gear. Drive out pin securing differential pinion shaft in case and take out shaft, pinion, side gears, and thrust washers.

Differential Assembly: Lubricate all parts with differential lubricant. Install side gears and thrust washers, pinion gears and thrust washers and the differential pinion shaft. Secure pinion shaft with locking pin (stake pin in place to avoid having it fall out). Position the ring gear on the case and secure in place with capscrews and new lockwashers. Tighten capscrews to 50-60 ft. lbs. Bend tangs of lockwashers up against capscrews.

▷*REPLACEMENT DIFFERENTIAL GEAR & PINION CAUTION: See Parts Production Change above for different type gears and pinions which must be used together.*

Differential Bearing & Ring Gear Backlash Adjustment: Install side bearings on differential assembly without shims. Install differential assembly in housing (without pinion shaft) and use dial indicator to measure total endplay of unit and note this figure. Select shims (furnished .003", .005", .010", thick for Ford; .0025-.0035", .0045-.0055", .009-.011", .027-.033" for Lincoln & Mercury) equal to this amount plus shims equal to desired bearing preload which is TOTAL SHIM PACK for the differential assembly (total for installation on both sides of case). After pinion installed (see below) in housing, re-install differential assembly without shims and measure endplay from point where ring gear and pinion backlash is zero to point where differential assembly is solidly against left hand bearing (mount dial indicator at back face of ring gear, slide carrier back and forth). Select shims equal to this indicator reading less .005" for desired backlash from the total shim pack (above) and install these shims back of left hand differential assembly side bearing cone, install remaining shims of total shim pack behind right hand differential assembly side bearing cone. See "Rear Axle Assembly" below, for installation of differential assembly.

Car Model	Pinion Preload Shims Shim Thickness
Ford (1948-54)	007-.009"
Ford (1955)	.004-.009"
Lincoln (1949-55)	.005-.009"
Mercury (1949-54)	.005 .009"
Mercury (1955)	.010"

▷*1955 LINCOLN & MERCURY TOOL NOTE:* Tool 4205-A is available for use on 1955 Lincoln & Mercury Rear Axles. Tool consists of two dummy bearings which replace differential case side bearings in making adjustments as outlined above. Procedures remain the same.

Ring Gear Backlash & Gear Mesh: Measure backlash with a dial indicator. If not within limits of .003-.006" (Ford Truck), .003-.008" (Others), adjust by shifting shims behind side bearing cups from one side of the carrier to the other but do not change total shim thickness which would affect bearing pre-load above. Check backlash at four equal spaced points around ring gear. Backlash must be within limits and must not vary more than .002" between these checking points.

REAR AXLE (Assembly): Assemble rear axle in the following sequence:

Pinion Bearing Assembly Installation: Lubricate all bearings and thrust washers with differential lubricant before installation. Install front and rear bearing cups in housing using Tool 4628-D (Lincoln & Mercury), Tool 4628-N (Ford) for rear bearing cup; Tool 4628-B (Lincoln & Mercury, Tool 4628-N (Ford) for front bearing cup *(CAUTION*—Re-install shims behind rear bearing cup. If new parts being used, install approximately .030" shim thickness to check pinion setting). Install rear bearing cone and bearing assembly on pinion shaft, insert pinion in housing and check pinion setting (below) to determine correct thickness of shims required. If correction required, remove rear bearing cup from housing and re-install with correct number and thickness of shims behind bearing cup. Lubricate bearings and insert pinion in housing, place bearing spacer on shaft (spacer not used on Lincoln), re-install bearing adjusting shims on shaft (same thickness as removed unless new parts installed, in which case install approximately .065" shim thickness to check bearing adjustment). Install pinion shaft front bearing cone and roller assembly with Tool 4858-B and tighten tool nut to torque indicated in "Tightening Torques" table below. Check pinion bearing preload (see below) and add or remove shims from shaft behind front bearing cone until correct bearing pre-load secured. Remove tool, install oil slinger, wick, and gasket, and oil seal (use Tool 4676). See that oil deflector on companion flange is in good condition (new deflector can be installed with Tool 4859), install companion flange with Tool 4858-B tighten companion flange nut to torque indicated

Pinion Nut Tightening Torque	
1948-54 Ford	140-180 ft lbs.
1955 Ford	200-220 ft. lbs.
1949-54 Lincoln & Mercury	100-150 ft. lbs.
1955 Lincoln & Mercury	180-200 ft. lbs.

Pinion Bearing Preload: Turning torque with pinion rotating should be as indicated in table below (disregard torque required to start pinion) with nut on end of pinion shaft properly tightened to torque indicated in "Tightening Torques" table above. To check preload, position axle so that pinion shaft is vertical, use torque indicator (with Tool 4858-B) and note indicator reading with shaft rotating.
Adjustment—If torque reading low, remove shims from shaft behind front bearing cone; if reading high, add shims at this point Shims furnished .003", .005", 010", .030" thick.

Car Model	Pinion Bearing Preload Preload (In. lbs.)
Ford (1948-54)	8-12
Ford (1955)	10-30
Lincoln & Mercury (1949-54 old bearings)	8-12
Lincoln & Mercury (1955 old bearings)	10-20
Lincoln & Mercury (new bearings)	18-20

Pinion Setting: Pinion position must be checked when new parts installed or when same number and thickness of shims, as removed from behind rear bearing cup, not re-installed. Check pinion position with Pinion Depth Gauge Tool 4020-A (Ford), 4020-B (Lincoln & Mercury) as follows: With pinion inserted in housing, install gauge in differential side bearing bores (use large diameter rings of Tool 4020-B for Lincoln, and small rings for Mercury). Install bearing caps and torque capscrews to 60-70 ft. lbs. Bolt anvil clamp on axle housing flange directly over pinion, install anvil under clamp so that anvil rests on face of pinion and contacts gauge micrometer (Lincoln & Mercury). Check micrometer reading (Micrometer is part of Tool 4020-B. Outside type micrometers must be used with Tool 4020-A) which should agree with table below for all standard pinions marked "0." If micrometer reading greater than figure in table, subtract equal thickness of shims from .030" shim pack installed behind pinion rear bearing cup; if micrometer reading less than figure in table, add equal thickness of shims as above; and finally correct this shim thickness for all pinions marked other than standard "0" pinion as follows:
Pinion Marking Note—Standard pinions are marked "0." When installing a "—" (minus) pinion ADD shims equal in thousandths to the figure following this minus sign on the pinion; for "+" (plus) pinions, SUBTRACT shims similarly from the standard shim thickness (for pinions marked "0"). These shims furnished in thicknesses of .003", .005", .010" (Ford), .0025-.0035", .0045-.0055", .009-.011", .027-.033" (Lincoln & Mercury).
▷*CAUTION—Changing shim thickness to adjust pinion position will disturb bearing adjustment unless same shim thickness is added or removed from shaft at front bearing cone*

Pinion Gauge Setting (Gauge 4020-B)
(For Standard Pinions Marked "0")

LINCOLN	
1949-55 (All Ratios)	.562"
MERCURY	
1949-50① (4.27-1, 4.55-1)	500"
1949-50① (3.91-1)	593"
1950-53 (With 8½" Ring Gear)	.625"
1954-55 (All Ratios)	.562"

Pinion Gauge Setting (Gauge 4020-A)
(For Standard Pinions Marked "0")

FORD	
1949-51 Sta. Wgn. (3.91-1)	1.657"
1949-51 Sta. Wgn. (4.27-1)	1.750"
1948-51 ½-Ton & F-1 Trucks	1.750"
1952-55 (All Ratios)②	1.625"

①—Early 1950. Later 1950 used 8½" ring gear.
②—With 8½" ring gear.

FORD & MERCURY "SEPARATE CARRIER TYPE" HYPOID

Ford, Pass. Car Exc. Sta. Wgn. (1949-55)
Ford, Sedan Delivery (1949-51)
Mercury, Except Sta. Wgn. (1952-54)

►*NOTE: See "Ford, Lincoln, Mercury Hypoid (Integral Carrier)" for other Ford & Mercury applications.*

►CHANGES, CAUTIONS, CORRECTIONS

►*REAR AXLE LUBRICATION CAUTION: If necessary to change rear axle lubricant before 5000 miles, refill axle with M-4642-A or B lubricant. After 5000 miles of operation, Multi-Purpose type gear lubricant can be used for refilling.*

►*1949 PINION GEAR PRODUCTION CHANGE:* Early 1949 rear axle pinions had shims placed between rear bearing cup and carrier housing. Later type has shims placed between shoulder on pinion gear and rear bearing cone. Later type pinion can be used as replacement for earlier type (ring gear and pinion in matched sets).

►*1951-54 DIFFERENTIAL GEAR CASE CAUTION:* Differential Gear Case, Part No. 1A-4205 (Painted Red), used with 3.31-1 ratio carrier and gear assembly. Part No. 8A-4205 used with other ratios. THESE CASES ARE NOT INTERCHANGEABLE.

►*1952-54 MERCURY REAR AXLE "CLINK" CORRECTION:* Hardened, phosphate coated slinger, Part No. MA-4670-A, has been released to alleviate above condition, replacing Part No. 0A-4670. To install proceed as follows: Remove drive shaft assembly. Remove companion flange only from rear axle. Polish end of companion flange where it contacts slinger, with fine crocus cloth. Reassemble companion flange, torque pinion nut to 150 ft. lbs. Install drive assembly.

DESCRIPTION: Semi-floating hypoid gear, Hotchkiss drive, with separate differential carrier assembly which can be removed for work.

AXLE SHAFT REPLACEMENT: Remove wheel and tire assembly, then remove the Tinnerman nuts that secure brake drum to axle flange. Remove brake drum. Working through the hole provided in axle shaft flange, remove nuts securing brake carrier plate to axle housing. Pull axle shaft assembly out of housing with Axle Shaft Puller Tool. 4235-N (Ford), 4235-A (Mercury). Do not dislodge brake plate or damage oil seal in housing. Install one nut to hold brake plate in place.

Wheel Bearing Replacement (Ford): Remove bearing retainer from shaft with Tool 2240-N. Use puller to remove bearing or grind through both races and lift off bearing *(CAUTION–Do not re-use bearing).* To install bearing, place retainer plate on shaft, using Tool 1225-N to press new bearing firmly in place against shoulder on shaft. Press retainer ring firmly against bearing.

Wheel Bearing Replacement (Mercury): Cut wheel bearing retainer with chisel, then remove bearing with Tool 1225-C. Use Tool 1225-B to replace bearing. Press into place. Use same tool to press on bearing retainer.

►*CAUTION: Use extreme care not to damage oil seal bearing surface on axle.*

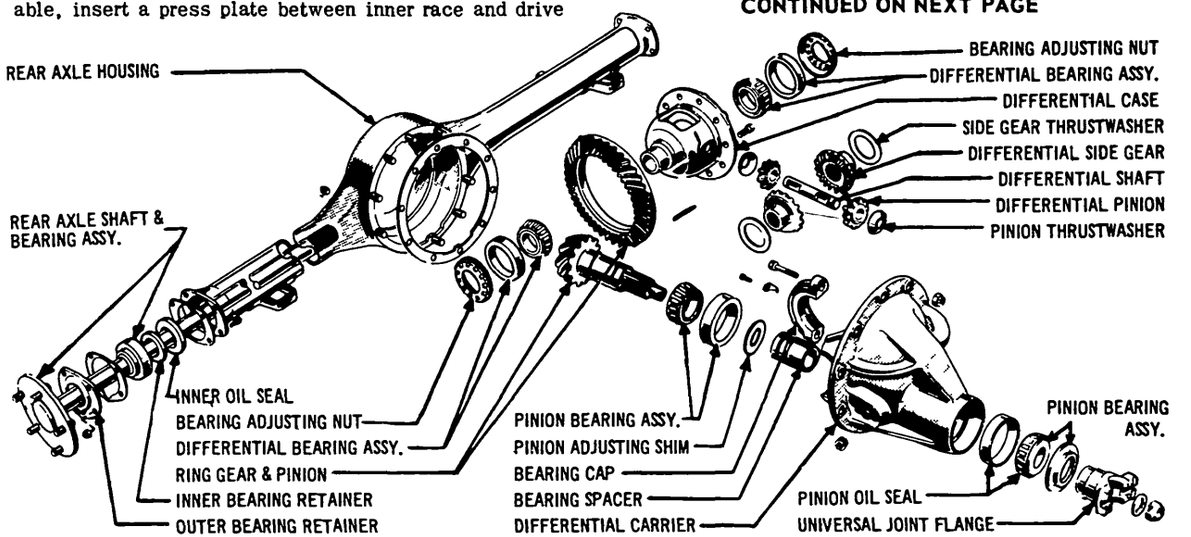
Oil Seal Replacement–Soak new seal in engine oil for at least ½ hour. Use Tool 4235-N or A to drive seal into place against shoulder in housing. Check fit of seal in housing to prevent oil leaks around seal.

REAR AXLE ASSEMBLY REMOVAL: *See "Rear Axle" on Car Model pages.*

REAR AXLE OVERHAUL: *(NOTE–It is not necessary to remove rear axle assembly from car for overhaul).* After axle shafts removed, proceed as follows:

Differential Carrier: Removal–Disconnect propeller shaft rear universal joint. Drain lubricant from housing and remove carrier to housing nuts. Remove carrier from housing.

Disassembly–Before disassembling carrier, clean thoroughly and inspect drive pinion, drive gear, and case assembly for endplay. Inspect gear tooth pattern to determine if gears are worn, defective, or out of adjustment. Check backlash and drive gear runout. Mark differential bearing caps and carrier supports with matching numbers to insure proper reassembly. Remove differential adjusting nut locks, bearing caps and adjusting nuts. Lift differential assembly out of carrier. Remove universal joint flange nut and washer, then pull flange off drive pinion. Lift drive pinion, rear bearing and bearing spacer out of carrier. Remove oil seal using Tool 1175-H or B, and lift oil slinger and bearing out of case. Drive pinion bearing cups out of carrier with a brass drift, or use Tool 4628-P or F.



Differential Case Disassembly–Remove differential bearings with Puller 4221-N or C. Remove capscrews attaching drive gear to differential case and tap gear off case with a soft hammer. Drive pinion shaft locking pin out of case with a drift, working from the drive gear side of case. Remove pinion shaft and remove differential pinions, side gears, and thrust washers.

Drive Pinion Disassembly–Remove rear bearing from drive pinion with Puller 4221-N or C. If tool not available, insert a press plate between inner race and drive pinion out of bearing. Remove shims from drive pinion, noting total thickness of shim pack for use at reassembly.

Differential Carrier: Reassembly–If replacement of drive pinion or drive gear is necessary, both parts must be replaced. When differential case is being replaced, be sure that the new case is the same as the original case. Coat all parts with differential lubricant before installation and use new gaskets.

Drive Pinion Adjustment (Master Pinion Tool Method)–Make sure that bores in carrier are free of burrs and metal chips, then install drive pinion bearing cups in carrier using an arbor press and a suitable driver. Slide drive pinion rear bearing on Master Pinion Tool 4610-CC, then position tool in carrier. Install front bearing on tool, then install universal joint flange, washer, and nut using Tool 4858-P or E. Oil bearings then tighten nut until bearing preload is 15-20 inch pounds. Check preload with Tool 4610-N. *(NOTE–Alternately turn drive pinion while tightening nut to properly seat bearings).* Install Pinion Depth Gauge 4610-A or 4610-P. Measure distance between depth gauge and pinion with a 2-3" micrometer. Remove pinion depth gauge and master pinion tool from carrier. Check number etched on end of pinion to be installed. With this number and the micrometer reading, select total shim thickness requirement (see "Pinion Setting Shim Table". As an example, a reading of 2.531" from Tool 4610-A *(reading from Tool 4610-P would be .500" less)* with a pinion marked "17", requires .033" in shims. Shims are available in .010", .011", .012", .013", and .016". Install proper shims on pinion shaft, then press the rear bearing on pinion until it is seated against shims *(CAUTION–When checking pinion depth, always use the same bearings that are to be used for service in the axle).* Install pinion assembly in carrier, then install a new bearing spacer and front bearing. Place the oil slinger and seal on pinion shaft, and

CONTINUED ON NEXT PAGE

FORD PASS. CAR REAR AXLE (SEPARATE CARRIER)

FORD & MERCURY HYPOID "SEPARATE CARRIER TYPE" (C ntinued)

drive seal into place with Tool 4676-A. Install universal joint flange with Tool 4858-P or E, and install washer and nut. Alternately turn the pinion while tightening nut until bearing preload is 22-28 inch pounds (new bearings), or 13-18 inch pounds (used bearings).

PINION SETTING SHIM TABLE

Micrometer Reading Using Tool 4610-P	Micrometer Reading Using Tool 4610-A	Pinion Marking								
		12	13	14	15	16	17	18	19	20
2.025	2.525	.022	.023	.024	.025	.026	.027	.028	.029	.030
2.026	2.526	.023	.024	.025	.026	.027	.028	.029	.030	.031
2.027	2.527	.024	.025	.026	.027	.028	.029	.030	.031	.032
2.028	2.528	.025	.026	.027	.028	.029	.030	.031	.032	.033

2.034	2.534	.031	.032	.033	.034	.035	.036	.037	.038	.039
2.035	2.535	.032	.033	.034	.035	.036	.037	.038	.039	.040

Driv Pini n Adjustment (Tooth Pattern Method)–Make sure bores in carrier are free of burrs and metal chips, then install drive pinion bearing cups in carrier. If the original drive pinion is being used, install the original shim pack on drive pinion. If a new pinion is being installed, and the drive pinion marking is the same as the old pinion, install original shims. However, a thicker shim pack is necessary if the number on the pinion is greater, or a thinner shim pack if the number is smaller. For instance, if the number on the old pinion was "15", and the number of the new pinion is "17", install a .002" thicker shim pack. Conversely, a .002" thinner shim pack should be used if the new pinion number is "13". If the old bearings are to be used, increase the shim pack thickness .002". If the old shims are not available, use a shim pack .030" to .032" thick for a trial build up. Install the shim pack, then install the pinion rear bearing. Install drive pinion assembly in carrier, install a new bearing spacer, then install pinion front bearing. Install oil slinger on top of front bearing. Place oil seal over end of drive pinion shaft, then drive oil seal into place with Tool 4676-A. Install universal joint flange with Tool 4858-P or E. Install the flange washer and a new nut. Alternately turn the pinion while tightening the the nut. *(CAUTION–Do not damage the spacer on drive pinion by over-tightening the drive pinion nut).* If new drive pinion bearings and a new oil seal have been installed, tighten drive pinion nut until bearing preload is 22-28 inch pounds (new bearings), 13-18 inch pounds (old bearing).

Diff r ntial Cas R ass mbly–Install differential side gears, pinions, and thrust washers in differential case. Install pinion shaft and pinion shaft lock pin. Position ring gear on case and install the drive gear capscrews and tighten screws to 35-40 ft. lbs. Drive differential bearings on case hubs with Replacer Tool 4222-N or H, until they are flush with shoulder on case.

Installation–Place differential side bearing cups on bearings and position differential case assembly in carrier so the adjusting nuts will engage approximately the same amount of threads at each end of case. Thread adjusting nuts in carrier against bearing cups. Be sure that nut threads index with carrier threads. Carefully position the bearing caps on adjusting nuts, aligning marks made during disassembly. Be sure bearing cap threads index with adjusting nut threads. Install bearing cap bolts and tighten bolts until snug (final tightening will be made after ring gear and pinion tooth contact pattern is adjusted). Turn adjusting nuts while tightening bolts, to make sure threads are aligned. Back off the bolts ¼ turn to allow cups to move. Make sure the right hand adjusting nut is loose, then tighten the left hand nut (gear side of differential) until drive gear meshes with drive pinion. Feel the backlash as the nut is being tightened. Continue tightening the nut until no backlash is evident. Tighten the left hand nut **two additional notches** to properly seal and align the bearing cup. Loosen the nut until it just contacts the bearing cup when the backlash is zero. Tighten the right hand adjusting nut until it contacts the bearing cup, then tighten the right hand nut an additional 3 to 3½ notches to properly preload the differential side bearings. Tighten bearing caps to 75-80 ft. lbs. Install a dial indicator and measure the backlash in several locations *(CAUTION–*If backlash readings vary more than .003", the runout of the gear is excessive). The correct backlash is .003-.008". If not within limits, loosen bearing cap bolts ¼ turn, and move drive gear and case assembly as required. To move the case assembly, loosen one adjusting nut one notch and tighten the other adjusting nut one notch.

Gear Tooth Contact–*(NOTE–New gear sets have a heavy-load tooth contact pattern rolled on the gear teeth with a special machine. When a new set of gears is installed, duplicate this pattern as closely as possible).* Paint gear teeth with a suitable gear marking compound, place a load on the pinion flange and turn drive gear back and forth until a clear contact pattern is obtained. Compare this pattern with the tooth patterns shown in Rear Axle Section of Manual. *CAUTION–Whenever the drive pinion position is changed a new bearing spacer must be used to establish the correct preload.*

Differential Carrier Installation: Place a new gasket on rear axle housing studs, then position carrier assembly on housing. Install axle ratio identification tag on one of the upper carrier studs. Install all stud nuts and tighten to 30-35 ft. lbs. Fill axle housing to a level of the filler plug hole with rear axle lubricant.

FORD TRUCK FULL-FLOATING SPIRAL BEVEL (HOTCHKISS DRIVE)

Ford Truck, All exc. Half-Ton (1940-47)
F-2, F-3, F-4, F-5, F-6 School Bus (1948-52)

►**1950 F-4, F-5 PINION SHAFT PRODUCTION CHANGE**—Two different pinion shaft assemblies used. Early type has tapered shaft, later type has splined shaft.

DESCRIPTION: Spiral bevel gear, full-floating type with Hotchkiss drive. Similar to axle on previous truck models except that no torque tube is used.

REMOVAL OF AXLE: *See "Rear Axle" on car model page.*

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: This work can be done without disturbing wheels and hubs as follows:

Axle Shafts—Shafts can be removed without disturbing wheels and hubs as follows: Take out two screws in hub cap, remove cap. Remove nuts on 8 studs on axle shaft flange, turn two bolts (located between studs) in evenly to loosen axle shaft flange from hub. Then back off these two bolts, strike sharp blow on center of axle shaft flange to loosen locking cones on studs. Remove locking cones, pull shaft out. When installing shaft, see that new gasket in place under axle shaft flange, back off loosening bolts sufficiently to allow axle shaft to seat on hub, install locking cones on studs, tighten stud nuts evenly, then tighten two loosening bolts.

Wheel Bearing Adjustment—Remove axle shaft (above), remove outer locknut, lockplate, and grease retainer (except on ¾ and 1 Ton). Turn inner bearing adjusting nut up tight, then back nut off ⅛ turn, install lockplate being certain that locking pin in nut engages notch in lockplate (except ¾ & 1 Ton), bend lockplate tang against nut (¾ & 1 Ton). Install outer locknut and tighten securely. Rotate wheel by hand and see that it turns freely.

Wheel Bearing Assembly—To disassemble wheel bearings, remove axle shafts, remove outer locknut, grease retainer, lockplate and inner adjusting nut, remove wheel hub. Remove snap ring in inner end of hub. Use brass drift to tap inner bearing out until grease retainer comes out of hub, lift out bearing cone and roller assembly. Use puller 1239-Q to remove bearing cups from hub. Re-install parts in same manner using replacer 1239-P to install bearing cups and grease retainer in hub. Make certain that grease retainer snap ring installed, adjust wheel bearings after hub installed on axle (above).

RING GEAR BACKLASH: .004-.018". No adjustment.

OVERHAUL: Disassembly—Remove axle shafts and wheel hubs, take out capscrews holding left hand axle housing on right hand housing, remove left hand housing using care not to lose thrust pin and plate. Withdraw ring gear and differential assembly from housing (differential side bearing roller and cone assembly will come out on differential case hubs, bearing cones will remain in housing halves). Remove and service pinion assembly and differential assembly as directed below.

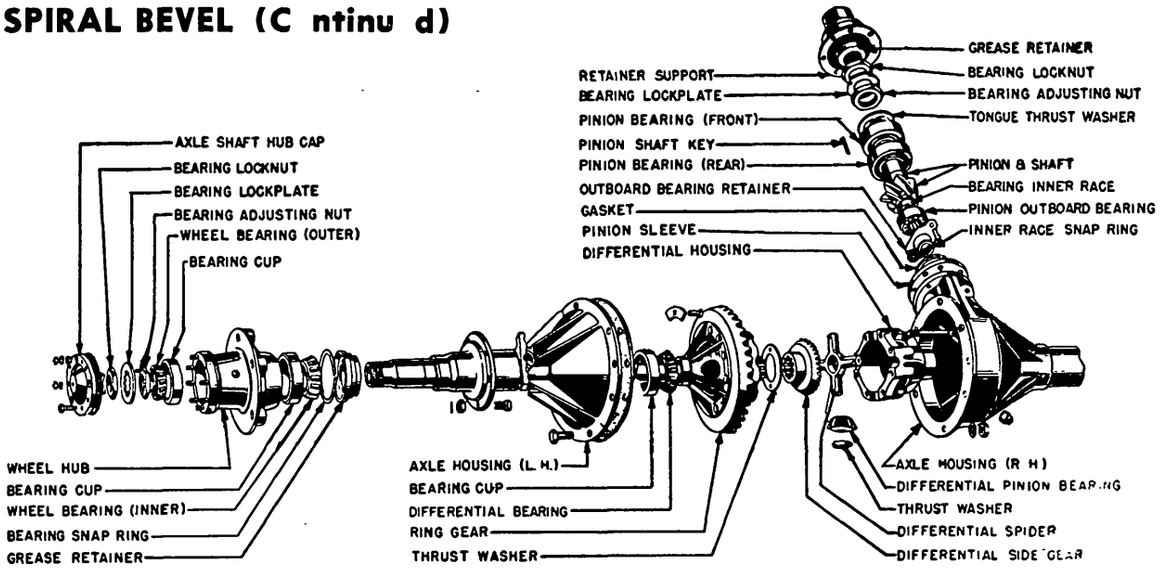
Pinion Bearing Assembly (Flanged Sleeve Type): To disassemble, take out screws mounting grease retainer and pinion sleeve flange on forward end of axle housing, lift off oil seal retainer. Remove pinion assembly using puller 4609-P and adapter 4609-P-4 (screw adapter on end of pinion shaft, mount puller on axle housing with mounting bolts passing

CONTINUED ON NEXT PA E

FORD TRUCK FULL-FLOATING SPIRAL BEVEL (C ntinu d)

through holes in pinion sleeve flange). Clamp pinion assembly in vise, remove locknut, lockwasher, adjusting nut, and thrust washer, lift pinion sleeve off (rear roller bearing roller and cone assembly will remain on shaft). Use puller 4221-A to remove and install this rear roller bearing on pinion shaft. To replace pinion shaft rear (pilot) bearing, remove inner race from end of pinion shaft by removing lock ring. Remove outer race and roller assembly from housing with replacer 4625-P, install new bearing with same tool and spacer 4625-P-7. To remove bearing cups from pinion bearing sleeve, use puller 4616-P. Install bearing cups with replacer 4616-Q and make certain that cups are flush with shoulder in sleeve. When assembling pinion, lubricate bearings with thin film of grease, insert pinion shaft and inner roller bearing in sleeve, install outer roller bearing ,thrust washer, and adjusting nut. Tighten adjusting nut until force required to turn pinion shaft is 12-16 in.lbs. which is correct bearing pre-load, install lockwasher and locknut.

Pinion Bearing Assembly Installation—Make certain that axle housing face and pinion sleeve flange are clean and smooth, align dowel pin in sleeve flange and hole in housing, press pinion assembly into housing until flange seats solidly, install new cork gasket in groove in sleeve flange, install oil seal retainer (see oil seal data below), install six capscrews and tighten screws securely.



Pinion Oil Seal—To replace oil seal, press old seal out of retainer using driver 4674-P-2 with adapter 4674-P-1. Install new seal with same tools. Make certain that sharp edge of seal leather faces toward inner end of retainer.

Pinion Bearing Assembly (Double Bearing Cup Type): Pinion bearing sleeve is not flanged (sleeve forms pinion bearing cups) and is retained in axle housing by separate pinion bearing retainer. Pinion bearing assembly is serviced in same manner as Flanged Sleeve Type and requires same special tools except that special adapter 4609-T-1 should be screwed on pinion shaft when pulling assembly out of housing. When assembling pinion, tighten adjusting nut until force required to turn pinion shaft is 12-16 ft. lbs.

Pinion Bearing Assembly Installation—Same as for other trucks (above) except that oil return hole in pinion bearing retainer must be aligned with oil hole in housing. **Pinion Oil Seal**—See above.

Pinion Setting: Pinion position not adjustable.

F-4, F-5 SPLINED PINION SHAFT (1950-51): Disassembly—Hold universal joint flange with Tool 4851, then remove cotter pin, nut and washer from drive pinion shaft. Remove flange using Tool 4858-Q. Remove bearing cover and oil seal assembly and take out pinion and cage assembly, using puller screws in holes provided in cage. Tap drive pinion out of cage, then remove outer bearing from cage. Remove bearing spacer from pinion and remove rear pinion bearing. Remove pilot bearing, using Tool 4625-D. Remove oil seal assembly from bearing cover, then remove bearing cups from cage assembly.

FORD TRUCK SPIRAL BEVEL GEAR, FULL-FLOATING AXLE (HOTCHKISS DRIVE)

Reassembly—Press pilot bearing on end of shaft, using a sleeve that applies pressure evenly to inner race of bearing. Install pilot bearing lock ring and press firmly into groove. Press bearing cups into cage until seated against shoulders. Lubricate with rear axle lubricant. Install rear bearing on shaft and insert pinion and bearing assembly into bearing cage. Install spacer or spacer combination on pinion shaft, press front bearing against spacer.

Preload Check—Place pinion and cage assembly in vise and intall universal joint flange and tighten to 300-400 ft. lbs. torque. Wrap a soft wire around pinion bearing cage, and using a pound-pull scale, pull on a horizontal line. If rotating torque is not 12-18 inch lbs., install a thinner spacer to increase the preload, or a thicker spacer to decrease the preload. Install a new oil seal bearing cover. Position pinion and cage assembly over studs on housing and tap into place with a soft hammer. Tighten nuts to 70-90 ft. lbs.

Differential Assembly:—To disassemble take out capscrews holding right hand half of differential case on left hand half, remove right half of case and lift out differential gears, pinions and pinion shaft. To remove differential bearing rollers and cones from differential case hubs, use special puller 4221-A with 4221-A-5 adapter. Replace these bearings with driver 4221-T (¾ & 1 Ton), 4221-P (Other Trucks). Use puller 4616-P (¾ & 1 Ton), 1239-Q (Other Trucks) to remove bearing cups from axle housings, replacer 4222-P to install these bearing cups. Ring gear is serviced as a unit with differential case and should not be removed. Replace differential spider if worn to diameter less than .745" (¾ & 1 Ton), .868" (Other Trucks), at gear bearing surfaces, replace spider gears if inside diameter worn to more than .758" (¾ & 1 Ton), .881" (Other Trucks). Replace side gears if splines worn so that backlash of new axle shaft in gear is more than .004". Replace spider gear thrust washers if worn to thickness of less than .025" (all models), side gear thrust washers if thickness less than .057" (¾ & 1 Ton), .055" (Other Trucks). No adjustment.

Ring & Pinion Gear Backlash: .004-.018".

Assembly Note:—When reassembling axle, see that thrust block and thrust pin not worn and properly installed in left hand axle housing, use one 61-4035 gasket (¾ & 1 Ton), BB-4035 gasket (Others) between axle housing halves.

Ring Gear Thrust Block: Thrust block can be removed by driving out retaining pin using a long nosed drift to drive pin out of left hand axle housing. Install new thrust block in same manner making certain that pin is seated firmly in housing.

FORD TRUCK TWO-SPEED

Trucks, 1½ & 2-Ton; F-5, 6; F-500, 600 (1946-55) Optional Equipment.

▷*AXLE RATIO NOTE:* This axle provides ratio of 5.83-1 for speed with reduced engine RPM (planetary gears locked out) and a ratio of 8.11-1 for power (with planetary gears operating). 6.33-1 to 8.81-1 ratio is also available since 1950.

▷*CONTROL NOTE:* Planetary system vacuum controlled 1946-52, electrically controlled 1953 and later.

DESCRIPTION: Two-speed planetary type, with spiral bevel type ring gear and pinion. Axle is full-floating type with Hotchkiss Drive.

CONTROL UNITS (Vacuum & Electrical): *See "Control Units" below.*

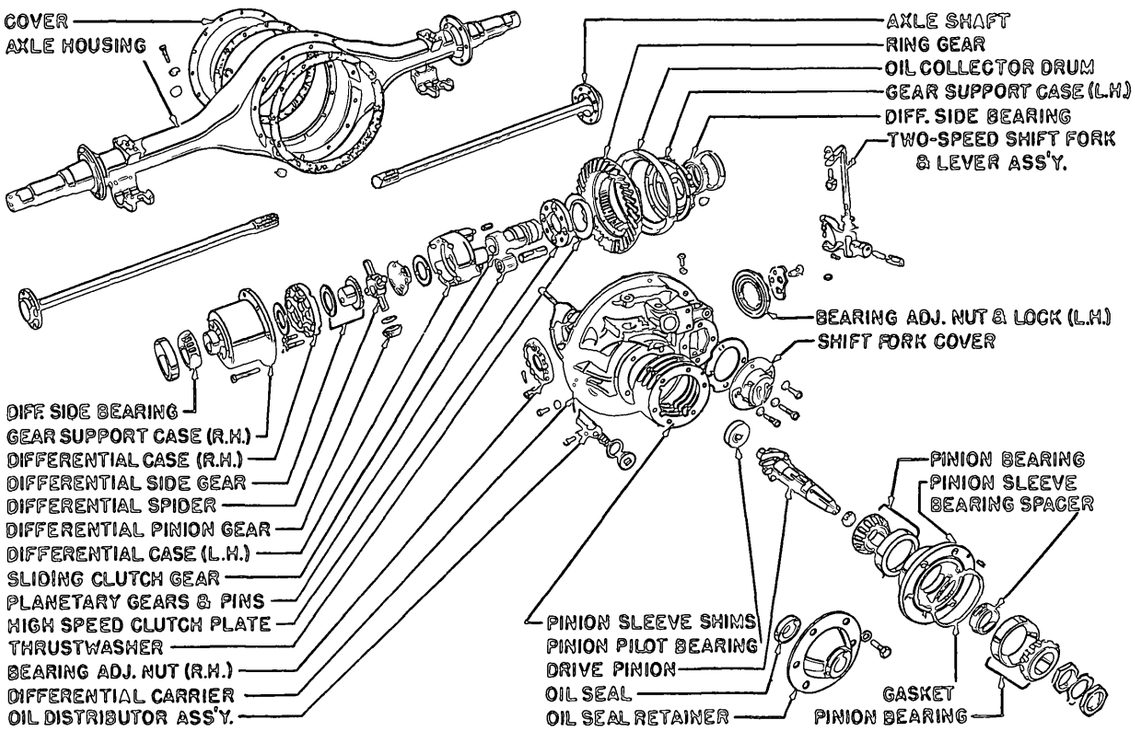
REMOVAL OF AXLE: *See "Rear Axle" on Car Model page.*

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: Same as for full-floating truck axle. *See "Ford Truck Full-floating" Rear Axle.*

REAR AXLE OVERHAUL: Carrier—Proceed as follows:

Disassembly: Remove oil distributor locating screw and lockwasher from top of carrier (to left of oil filler plug), remove oil distributor plug and gasket, pull oil distributor and spring out of housing. Take out four capscrews and lockwashers retaining shift fork cover (CAUTION—Note location of the one longer capscrew and re-install this in same hole when reassembling axle), remove cover and gasket, remove plunger and spring from shift fork, pull shift lever out of shift fork (do not remove felt washer and retainer unless worn and require replacing), slide shift fork from housing, pull sliding clutch gear out. Mark right and left hand bearing adjusters and bearing caps to insure correct reassembly, remove lock wires, take out bearing cap bolts, remove bearing caps, adjusting nuts, and locks. Lift differential assembly out of carrier. Remove lock wire and bolts from ring gear, remove right hand gear support case by tapping gear with a brass hammer, remove left hand gear support case, high speed clutch plate thrust washer, and oil collector drum. Slide ring gear off differential and planetary gear case. To disassemble differential and planetary gear assembly, remove high speed clutch plate by tapping with a soft hammer (strike alternately and evenly on each side). Remove planetary gears and planetary gear bronze pins. Take out 12 capscrews in differential case, separate right and left halves of case, lift out differential side gear and thrust washers, pinions and thrust washers, and spider. To remove drive pinion assembly, remove cotter pin and nut on end of shaft, pull or drive universal shaft flange off end of shaft, take out six capscrews in pinion retainer. Drive pinion assembly out of housing using a soft brass drift to drive on inner end of shaft.

Pinion Bearing Assembly: To disassemble, clamp assembly in a vise, bend lockwasher ears away from pinion bearing nuts, remove nuts and lockwasher. Lift pinion sleeve (including bearing cup and spacer) off shaft. To replace pinion bearings, use puller to remove bearing cups from pinion sleeve or insert bar 3 7/16" long through hole in side of sleeve so that it rests on inner end of one bearing cup and press cup out in an arbor press, remove second cup similarly. Remove bearing roller and cone assemblies from pinion shaft with a puller. To remove rear (pilot) bearing, remove lockring on pinion end of bearing using a sharp screwdriver blade, slide outer race off, remove bearing rollers, press inner race off end of shaft. Press new rear bearing on shaft and stake bearing at four points (place a steel ball on end of shaft at inner race, strike ball with a hammer). Press bearing cups in pinion sleeve until they seat solidly against shoulder, press one roller and cone assembly on pinion shaft, insert pinion shaft in sleeve, place bearing adjustment spacer on shaft (see Pinion Bearing Adjustment below), install second roller and cone assembly, install bearing nut, lockwasher, locknut (bend lockwasher ears over nuts after bearing adjustment checked).



Pinion Bearing Adjustment—With pinion nut tight, force required to turn pinion shaft should be 12-16 in. lbs. If bearing adjustment not correct, install spacer of different thickness on pinion shaft between bearing cones. This spacer furnished in 12 different thicknesses from .513"/.514" thick (min.) to .543"/.544" thick (max.) for bearing adjustment.

Pinion Oil Seal—To replace oil seal, drive old seal out with a small punch, install new seal with Driver 4674-P-2 and Adapter 4674-P-1. Seal must be installed with sharp edge of leather facing inner end of retainer.

Pinion Setting: Pinion position controlled by shims installed between pinion sleeve flange and mating face of carrier. When installing pinion assembly, make certain that these faces are clean and smooth, install same thickness of shims between carrier face and pinion sleeve flange as removed when axle disassembled, line up dowel pin in sleeve with hole in carrier, drive assembly in until it seats solidly. Install new cork gasket in pinion sleeve groove, install oil seal retainer taking care that seal leather not damaged by keyway in shaft. Install and tighten six capscrews and lockwashers. After completely assembling axle, check ring and pinion gear mesh. Pinion position can be adjusted by changing shim thickness under sleeve flange. These shims furnished in four thicknesses from .00975"/.01025" (min.) to .028"/.032" (max.) for this adjustment.

Differential Gear & Bearing Assembly: To remove differential side bearings, tap old bearing roller and cone assemblies off drive gear case hubs using a drift inserted through holes in case back of each bearing (drive alternately and evenly through both holes). Press new bearings on hubs. Replace differential spider if worn to diameter of less than .934" at gear bearing surfaces, replace spider gears if inside diameter worn to more than .944". Replace side gears if splines worn so that backlash of new axle shaft in gear is more than .004". Replace spider gear thrust washers if thickness less than .025", side gear thrust washers if thickness less than .058". When reassembling unit, lubricate gears and thrust washers, make certain that long and short bolts installed in proper holes (8 long, 4 short), lock bolts with lockwire after properly tightened. Install planetary gear pins in holes in differential case, in-

CONTINUED ON NEXT PAGE

1946-52 FORD TRUCK TWO-SPEED REAR AXLE

FORD TRUCK TWO-SPEED (C nt.)

stall gears, install high speed clutch plate on planetary gear pins with chamfered teeth in toward planetary gears, tap plate in place with a brass hammer. Place right hand gear support case on bench with open end up, lubricate and install thrust washer in case, install differential assembly with planetary gears upward, install ring gear with teeth facing downward and mesh internal gear teeth with planetary gears, line up bolt holes in gear with bolt holes in case. Place oil collector drum on ring gear with open side toward gear and engage tongues on drum in gear recesses. Lubricate high speed clutch plate thrust washer and install it on high speed clutch plate. Install left hand gear support case, install six bolts with heads against flange of right hand gear support case, tighten all bolt nuts securely and secure nuts with lockwire.

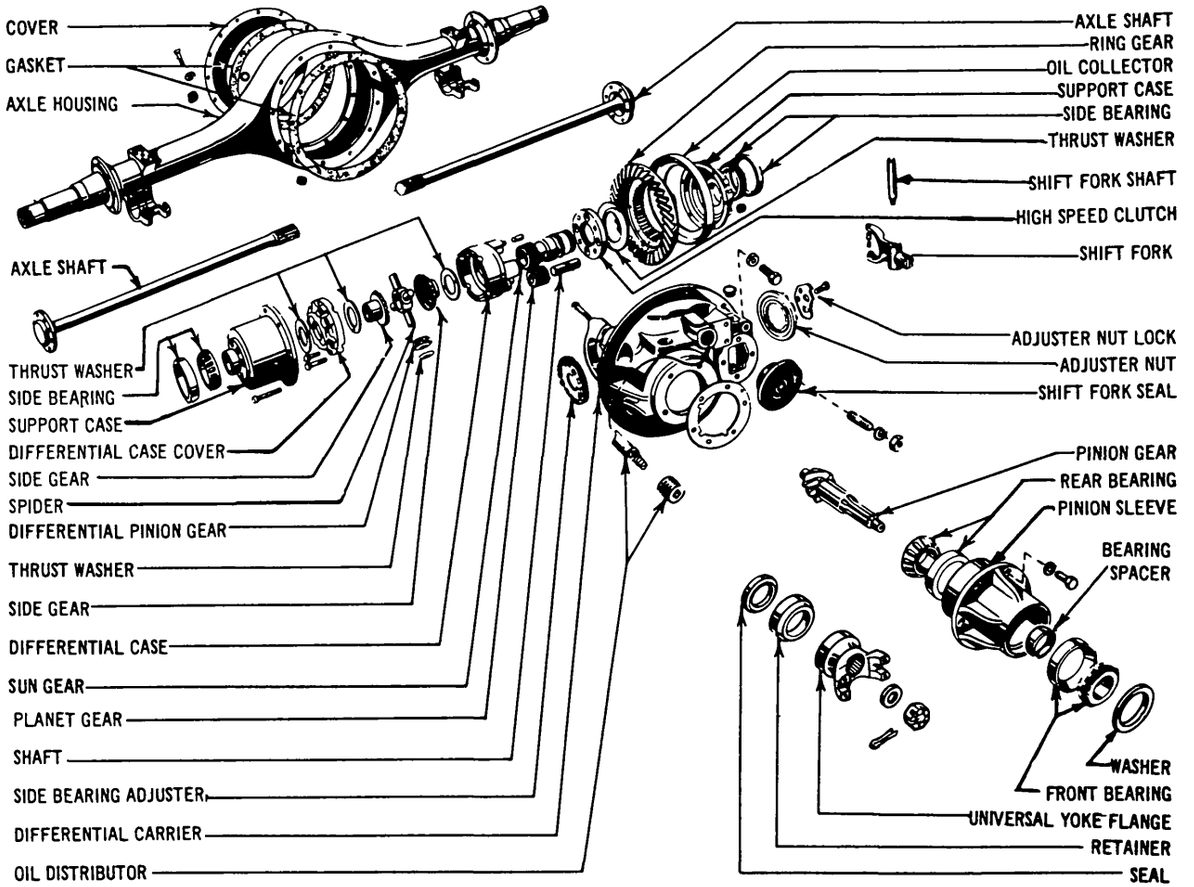
Differential Bearing Adjustment—When installing differential assembly in carrier, lubricate bearings with thin film of grease, install bearing cups and adjusters, hold adjuster away from threads in carrier until bearing cap bolts are started, then lower cap and adjuster into mesh with carrier threads. Make certain that adjuster properly meshed in both cap and carrier before tightening cap bolts. Turn left hand adjuster up until ring and pinion gears mesh loosely, tighten right hand adjuster up as tightly as possible, then back off adjuster one notch. This setting will give correct bearing pre-load. After checking ring and pinion gear backlash, tighten both bearing cap bolts very tight, secure bolts with lockwire, install adjuster locks.

Ring Gear Backlash Adjustment: Back off the right hand differential bearing adjusting nut and turn up left hand nut until backlash between gears is .004-.018" (measured at gear teeth). Paint gears to check mesh, adjust ring gear position for correct lengthwise contact, adjust pinion position for correct contact on tooth. Then adjust bearings.

TWO-SPEED CONTROL UNIT

VACUUM CONTROL UNIT OPERATION: High Speed Range—When the control knob on dash is pulled out, control lever is pulled downward causing control valve and seat to make an air tight seal and creating an opening through control valve body that is entirely sealed off from any air leaks Since check valve ball is spring-loaded, ball immediately seats itself if vacuum draw drops below compression strength of spring With ball seated, system is vacuum tight (This condition exists when system is under vacuum and throttle is held wide open) Air is drawn from the front side of diaphragm of the axle shift diaphragm assembly by manifold vacuum Atmospheric pressure behind the diaphragm causes it to move forward compressing push-rod spring The pushrod, attached to the diaphragm, actuates clutch shaft lever of axle through clevis and pin A speedometer adapter and diaphragm assembly mounted on rear of speedometer head compensates for variations in speed of drive shaft between high and low speed range of axle

Low Speed Range—When control knob on dash is pushed in, control lever is pulled upward lifting plunger off valve seat and air enters system through an air filter Disc on bottom of plunger fills bore of check valve body and seals off passage of air to intake manifold When system is filled with air, pressure on both sides of shift diaphragm is balanced and push-rod spring exerts enough pressure from its compressed position to shift axle into low range



ELECTRIC CONTROL UNIT OPERATION: High Speed Range—With control button on gear shift lever in upper position, current is supplied to the motor in the rear axle shift unit, causing motor to rotate in a clockwise direction and move drive screw assembly nut toward bottom of screw When nut has traveled far enough to wind the torsion spring, a contact bumper on the nut breaks electrical connection on automatic switch and stops the motor The nut is held at the end of its travel by a ball screw detent spring mounted on front cover As nut is moved downward, a spring winding lever, which pivots on a pin in the nut, winds the torsion spring The axle is ready to shift into high range as soon as the load on the rear axle gears is relieved The torsion spring is assembled in the unit under 50 to 80 lbs pressure When spring is wound, the tension is increased to 90 to 150 lbs. This additional pressure is used to shift the axle. When shift is completed, the ends of the spring come together, leaving the original tension in the spring This preload tension holds the axle in either range.

Low Speed Range—When button is placed in the down position, current is supplied to opposite field of motor and to speedometer adapter (adapter is mounted on speedometer and compensates for variation in speed of drive shaft between high and low ranges of the axle). Motor rotates in opposite direction (counter-clockwise) to that of high range operation, causing the drive screw assembly nut to travel toward top of screw Torsion spring is wound for a shift to low range which is accomplished in the same manner as for high range.

Electric Control Unit Lubrication—Change oil in unit every 10,000 miles using SAE 10W engine oil

VACUUM CONTROL UNIT OVERHAUL: Vacuum Control & Check Valve Removal—Remove cotter pin secur-

CONTINUED ON NEXT PAGE

1953-55 FORD TRUCK TWO-SPEED REAR AXLE

FORD TRUCK TWO-SPEED CONTROL UNIT (C nt.)

ing control wire to control lever. Loosen lockscrew, remove control wire and conduit from valve body. Disconnect vacuum line from check valve body, disconnect vacuum line. Remove control valve from mounting bracket. Remove speedometer adapter line from valve.

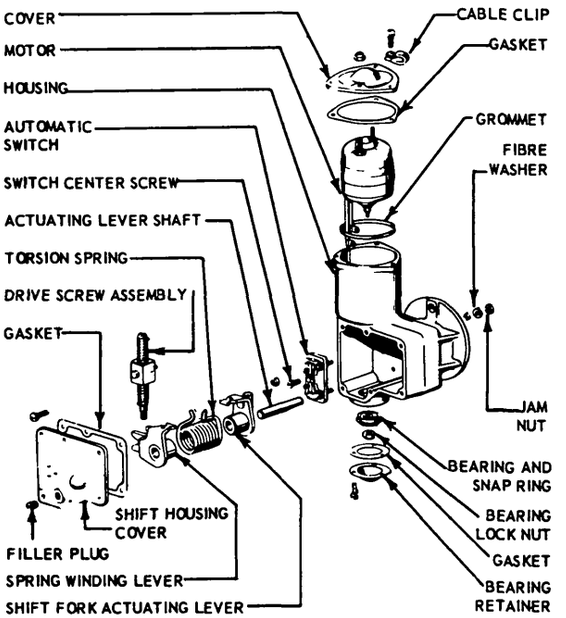
Disass mbly—Remove cotter pins from control lever, remove lever. Remove snap ring, plunger, screen, and plunger seal. Remove check valve body from control valve body, then remove check valve ball, seat, spring, and spring retainer. Remove control valve air filter cover from control valve body. Remove filter element and screen.

Insp ction & Parts R placement—Clean check valve ball seat, inspect seat for wear or deterioration. Test tension of check valve ball spring (spring should be just strong enough to hold ball up against ball seat). Clean and inspect control valve plunger seat. Clean air filter element in cleaning solvent, then allow element to dry before installation. Bores of control valve body and valve seats must be free of dirt before valve seats are installed.

Reass mbly—Place check valve ball seat in control valve body bore, chamfered side down. Lay ball on seat, then position spring seat on ball. Position check valve body over spring, thread body carefully into control valve body to prevent cocking of spring. Place control valve plunger seal in control valve body, chamfered side down. Then proceed, reversing removal procedure. With control lever in high range there should be a slight preload on lever spring. Lever spring can be bent slightly to increase preload.

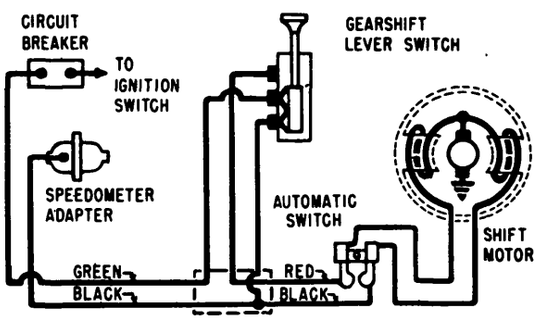
Installati n—Reverse removal procedure.

Axle Shift Diaphragm Assembly Removal: Loosen hose clamp, then disconnect hose from assembly. Remove cotter pin and clevis, shift rod boot and snap ring which retains diaphragm assembly.



Installati n—To install, reverse removal procedure, check over-travel of hole in shift rod in relation to hole in clutch shaft. Travel of shift rod should exceed travel of clutch shaft by approximately a half hole in both high and low range.

Speed m ter Adapt r & Diaphragm Assembly: Replace diaphragm if it fails to shift adapter to high range. Replace spring if diaphragm fails to shift adapter into low range.



ELECTRIC CONTROL UNIT OVERHAUL: *(NOTE—Speedometer adapter, circuit breaker, and control switch cannot be repaired and must be replaced if failur occurs).*

R moval: Disconnect one of the battery cables. Remove two shift housing to carrier stud nuts and lockwashers and remove unit from carrier.

Disassembly: Remove front cover and drain the lubricant. Turn drive screw until nut is in the center of the screw *(CAUTION—This is important to avoid damage to drive nut contact bumper).* Pull shaft out of tension spring assembly and remove assembly from housing. Remove screws and lockwashers which attach drive screw bearing cover to housing, then remove cover and gasket. Push down on screw assembly until the bearing is forced out of housing. Remove bearing retainer nut and bearing (hold shaft with a screwdriver inserted in drive slot). Remove locknuts from automatic switch terminals and remove motor wires from terminals. Remove motor cover screws and remove motor, cover, and gasket from housing. Remove jam nuts and fibre washers from terminals at rear of housing. Remove automatic switch center screw and lift switch out of housing. Mount torsion spring and lever assembly in a vise. Turn spring winding lever clockwise, and pull outward to disengage spring from lever.

1953-55 FORD 2-SPEED AXLE SHIFT ASSY.

1953-55 SHIFT CONTROL WIRING DIAGRAM

Inspection: Wash all parts except motor in cleaning solvent. Check all parts for signs of failure. Check automatic switch points for cleanliness and free movement. Make sure that points will close firmly under spring tension. Check operation of drive screw by rotating screw while holding nut. The screw must turn freely. When nut reaches end of screw, the screw should continue to turn but nut should not jam or run off end of screw. Turn screw in opposite direction and check operation at top end of screw. The fibre bumper in nut should be a tight press fit. Check stall torque of shift motor as follows: Place a wrench on rectangular drive of motor shaft. Hold wrench in one hand, hold motor itself in vise. Connect one motor wire to battery terminal and connect motor housing to other terminal. The wrench should tend to turn with a pull of about six inch pounds. Allow the wrench to turn very slowly, making sure that this torque is present for the full 360° turn of the wrench. *(NOTE—While testing the motor, do not allow it to overheat).* Check rubber diaphragm and make sure that spring clamp is in position in diaphragm groove and that it clamps diaphragm tightly around shift fork. Replace diaphragm if it is not in good condition or if it is not tight on shift fork.

Reassembly: Position rubber diaphragm on shift shaft (refer to lettering on face of diaphragm for correct position). If torsion spring assembly was disassembled, locate parts in the correct position and turn spring clockwise until end of spring is past the shift fork operating lever, then push lever inward until spring is locked in place. Position automatic switch in housing, then install switch attaching screw. Install fibre washers and jam nuts on the switch terminals at rear of housing. Place motor cover gasket on housing, then install motor and cover on housing. Install cover screws. Position motor wires on automatic switch terminals and install locknuts. Place drive screw assembly in housing and install drive screw bearing and bearing retainer nut. Tap bearing into seat in housing and install cover and gasket. Center drive screw nut on drive screw, making sure the contact bumper on nut is toward automatic switch. Position torsion spring assembly in housing and install shaft. Install housing cover and gasket and tighten attaching screws securely. Install lead wires on housing terminals with the **red wire on the bott m terminal.**

Installation: Position shift unit on carrier studs with the torsion spring swivel block installed in shift fork slot, then install nuts and lockwashers. Tighten nuts to 50-70 ft. lbs. Fill shift unit to level of filler plug with SAE 10W engine oil.

FORD TRUCK HYPOID "SPLIT HOUSING" TYPE

F-250, All Models (1953-Early 1955)

P-350, Parcel Delivery (1953-Early 1955)

►*NOTE:* "Ford, Lincoln, Mercury Hypoid (Integral Carrier)" Rear Axle used beginning Late 1955.

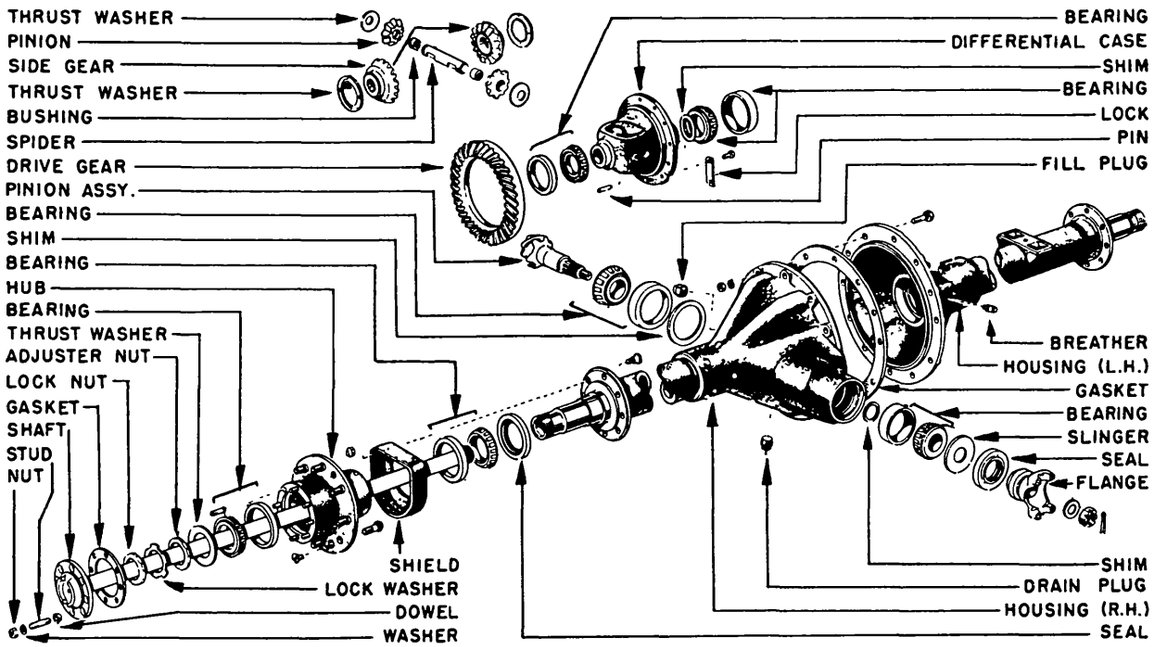
DESCRIPTION: Full-floating hypoid gear type with Hotchkiss drive. Axle housing is of split type, each half consisting of a steel tube riveted into a cast housing. Rear spring seats are welded to tops of axle housing tubes. Outer ends of tubes are machined for installation of wheel bearings and are threaded for installation of wheel bearing adjusting nuts. Flanges, forged integral with housing tubes, provide facilities for installation of brake carrier plates. Differential side bearing cups are pressed into machined bores in axle housing. Differential case is single piece type with two pinion gears.

REMOVAL OF AXLE: *See "Rear Axle" on Car Model pages.*

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: This work can be done without removing wheels and hubs, as follows:

Axle Shaft Removal—Drain lubricant from housing, remove axle shaft stud nuts and washers. Tap center of axle shaft flange to loosen tapered dowels, and remove the dowels. Remove axle shaft and gasket from housing.

Axle Shaft Installation—Install brake carrier plate, then hub and drum assembly, place new gasket on hub. Insert axle shaft in housing, lining up shaft splines with differential side gear splines. Install tapered dowels, lockwashers, and nuts on studs. Tighten nuts to 50-70 ft. lbs. torque.



Wheel Bearing Adjustment—Remove axle shaft (above), bearing locknut and washer. Tighten wheel bearing adjusting nut while rotating wheel back and forth, until a noticeable drag is felt, then back off adjusting nut ⅛ turn. Install bearing lock washer and locknut, and bend one tab of lock washer over adjusting nut and one tab over locknut. Install axle shafts.

OVERHAUL: Before disassembling axle, check drive gear backlash and record the reading for reference when reassembling axle. *See "Backlash Checking & Adjusting (below).*

Disassembly: Remove wheels, axle shafts (see "Axle Shaft Removal" above). Remove hub and drum assemblies and brake backing plates.

Differential Removal—Insert a piece of pipe slightly smaller than axle shaft splines, approximately two-thirds way through housing from the differential case side to prevent differential assembly from dropping. Remove nuts, washers, and bolts securing the two halves of axle housing together, and separate the axle housing. Remove differential assembly and pipe from housing. Remove differential side bearing cups from housing with Tool T53T-4222-A.

Differential Disassembly—Mark ring gear and differential case to insure reassembly in same position. Remove bolts and lock plate holding ring gear to differential case and remove the gear. Remove lock pin securing spider shaft in differential case with a long pin punch, then remove spider shaft, pinions, side gears and thrust washers. Remove differential side bearings with Tool T53T-4242-F (Be sure the side bearing cups are clamped in place over bearings when using the tool). Remove side bearing shims.

FORD TRUCK "SPLIT HOUSING" HYPOID AXLE

Drive Pinion Disassembly—Remove drive pinion shaft cotter pin. Hold universal joint with Tool T53T-4851-E, and remove nut and washer from drive pinion shaft. Remove flange from drive pinion shaft with Tool T53T-4851-A. Remove drive pinion from axle housing by rotating shaft while driving it from housing with a soft hammer. Remove drive pinion oil seal, oil slinger, and drive pinion outer bearing from housing. Remove outer bearing cup with Tool T53T-4621-A. Tap inner bearing cup and adjusting shims from axle housing with a soft drift. CAUTION—Measure and note thickness of shims found behind inner bearing cup. Remove the pinion bearing shims from pinion shaft, then press inner bearing from shaft with Tool T53T-4629-A.

Reassembly & Adjustment: Inspect gear teeth, bearings and bearing cups for signs of galling, pitting or wear, and replace any parts found to be defective. Clean all parts and blow dry with air.

Differential Reassembly—Lubricate all differential parts with gear lubricant, then position the thrust washers and pinion gears in case, and install differential side gears and differential spider. Install the lock pin that secures spider to differential case, and stake the lock pin in place. Align the marks (made at disassembly) on drive gear and differential case, then position drive gear on case. Be sure drive gear is properly seated, then install bolts and lock plates securing gear to case. Tighten bolts to 40-50 ft. lbs. torque. Press differential side gears on case with Tool T53T-4221-A, and arbor press. *(CAUTION—Do not install bearing shims at this time).* Install differential side bearing cups in each half of axle housing, using Tool T53T-4242-B (left side), and Tool T53T-4242-A (right side).

Differential Side Bearing Preload Adjustment—Position differential assembly in housing, using a piece of pipe to support assembly. Place new axle housing gasket on housing flange, then bring housing halves together. Install alternate housing bolts, washers, and nuts, and tighten bolts to 20-26 ft. lbs. Install a dial indicator on left-hand axle housing so that indicator stem enters access hole and contacts back face of drive gear. Push drive gear from side to side to check differential endplay. Rotate drive gear to several positions, and check endplay at each position. Remove differential from housing, and add shims behind side bearings necessary to bring differential preload within range .001-.005" (.003" preferred). *(NOTE*—Shim thickness should be equal to endplay plus .003".) Split shim pack equally and install shims behind both side bearings. Install differential in axle housing, and tighten alternate bolts to 20-26 ft. lbs. Install dial indicator stem against back face of drive gear. Rotate drive gear and recheck the runout. Maximum drive gear runout is .005".

Drive Pinion Assembly—Press the inner bearing on drive pinion shaft, using Tool 4615-A and arbor press.

Drive Pinion Installation—Position the original

CONTINUED ON NEXT PAGE

FORD TRUCK HYPOID "SPLIT HOUSING" (Cont.)

shims in axle housing, then install inner and outer bearing cups with Tool T53T-4616-A. Install shims on pinion shaft, then position pinion in axle housing. Install outer bearing on pinion shaft with Tool T53T-4261-A. Install universal joint flange with Tool T53T-4851-B. Hold flange with holding tool, then install flange nut and washers. Tighten nut to 200-250 ft. lbs. torque.

Pinion Bearing Preload Check—(With Differential Assembly Removed). Wrap a heavy twine several turns around shank of companion flange and attach scale Tool 6110-A. By pulling horizontally on scale check torque required to rotate assembly. If torque is not within 12 to 18 inch pounds, remove pinion shaft and add or remove shims from pinion shaft to bring torque within specified limits. Removing shims INCREASES torque, adding shims DECREASES torque. Reassemble pinion and recheck preload.

Differential Installation & Adjustment—Paint 12 drive gear teeth with red lead.. Insert pipe, used in axle disassembly, through housing half, then position differential assembly in housing. Install axle housing gasket, and bring both housing halves together. Install alternate bolts and nuts, then tighten bolts to 20-26 ft. lbs. torque. Install a dial indicator so contact arm rests against pinion shaft companion flange (on long side, opposite center of bolt hole) and check backlash between drive gear and drive pinion teeth. Rotate companion flange away from indicator until contact between gear teeth is felt. Set dial indicator at zero, rotate the flange against contact stem until all backlash is removed, then note reading on indicator. This reading will be exactly 1½ times the amount of backlash between gears. The correct lash is .008-.013" (dial indicator will read .012-.020"). If backlash is not within limits, add or remove shims behind pinion inner bearing cup until correct backlash is obtained.

Check Gear Tooth Contact—Insert axle shafts in housing. Hold axle shaft to impose a load on the gears, and turn universal joint flange several times in both directions to obtain tooth pattern. Disassemble axle and check tooth contact pattern (pattern should be fairly well centered on tooth, and slightly toward inner diameter, with ends of tooth not indicating a contact pattern). Add or remove shims from behind drive pinion inner bearing cup to correct depth for proper tooth pattern (CAUTION—Add or Remove the same amount of shims from pinion shaft outer bearing so pinion bearing preload will not change). When correct tooth pattern obtained, install remaining bolts, washers and nuts, and tighten nuts to 20-26 ft. lbs.

Drive Pinion Oil Seal Installation—Remove the universal joint flange after completing preload, ring gear tooth pattern, and backlash checks. Place oil slinger on pinion shaft, then install drive pinion oil seal with Tool T53T-4676-A. Install flange, washer and nut and tighten nut to 200-250 ft. lbs. torque. Install cotter pin.

FORD TRUCK HEAVY DUTY "SPLIT HOUSING" HYPOID

Ford Truck, F-6 Exc. School Bus (1950-52)
Ford Truck, F-350 Exc. Parcel Del. (1953-55)

DESCRIPTION: Hypoid gear type with full-floating axles and Hotchkiss drive, similar to SPIRAL BEVEL rear axle.

REMOVAL OF AXLE: *See "Rear Axle" on car model page.*

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: It is not necessary to remove wheels and hubs.

Axle Shafts—Remove axle shaft stud nuts and lock washers. Turn two shaft pulling bolts (located between stud hole) in evenly to loosen axle shaft from hub. Tap axle shaft in center of flange to loosen dowels and remove dowels. Pull shaft from housing. To install, place new gasket on hub and install axle shaft in housing, rotating axle to line up spline with splines in side gears. Install tapered dowels, lock washers and nuts on studs and tighten to 50-70 ft. lbs. (F-350), 84-93 ft. lbs. (F-6).

Wheel Bearing Adjustment—Remove axle shaft (above) bearing lock nut and lock washer. Tighten wheel bearing adjusting nut while rotating wheel back and forth, until a noticeable drag is felt. Back off adjusting nut ⅛ turn. Install bearing lock washer (NOTE—If adjusting nut is equipped with a dowel, make sure lock washer fits over dowel). Install bearing lock nut and tighten. If flange type lock washer is used, bend one flange over adjusting nut and one over lock nut. Install axle shafts.

Wheel Bearing Assembly—To disassemble, remove axle shaft, adjusting locknut, washer and adjusting nut. Remove wheel hub. Tap out inner bearing cone and grease retainer. Bearing races may be tapped out, using a brass drift. To re-assemble, install inner bearing race and bearing cone, install oil seal. Install outer race and bearing cone. Install axle on hub and adjust bearings (see above).

RING GEAR BACKLASH: .006-.012". Adjustment by shims behind bearing cups in axle housing.

OVERHAUL OF REAR AXLE ASSEMBLY:

Disassembly: Remove axle shafts and wheel hubs. Insert a length of pipe slightly smaller than axle shaft in left axle tube (facing front of truck) so as to engage differential case to prevent it dropping. Remove nuts and bolts from housing and separate it. Remove differential assembly, and pipe from housing.

Differential Disassembly—Mark differential case halves with a punch. Cut lock wires, remove nuts and separate case. Remove spider, pinions, side gears and thrust washers. Remove differential bearings using Tool 4221-K. Centerpunch rivet heads and drill through heads with a drill 1/32" smaller than rivet body. Press rivets out and remove ring gear. Using a suitable puller, remove bearing cups from each side of axle housing. *(CAUTION—Keep spacers found behind each cup together, and wire them to their respective axle housing half).*

Drive Pinion Cage Assembly Removal—Hold universal joint flange with Tool 4851, and remove nut and washer from pinion shaft. Use a suitable puller and remove universal joint flange. Remove drive pinion bearing cover and oil seal assembly. Remove drive pinion and cage assembly, using puller screws in holes provided in cage.

▷*CAUTION—Do not drive pinion from inner end as this will damage bearing lock ring groove.*

Drive Pinion and Cage Disassembly—Tap or press drive pinion from cage assembly. Remove outer bearing from cage and remove spacer or spacer combination from pinion. On F-350 Trucks, remove drive pinion rear bearing with Tool T53T-4242-F, then remove pilot bearing snap ring from inner end of drive pinion. Position pinion in press and remove pilot bearing. On F-6 Trucks, remove rear thrust bearing, then remove pilot bearing with Tool 4625-D and arbor press. Remove oil seal assembly from bearing cover. Remove bearing cups from cage assembly. *NOTE*—Tool T53T-4616-E can be used to remove outer cup on F-350 Trucks, then inner cup can be removed with a drift.

Reassembly of Rear Axle:

Drive Pinion Cage Reassembly—Press pilot bearing on end of pinion shaft, using a sleeve to apply pressure evenly to bearing inner race. Install snap ring and press into groove securely. Install bearing cups in bearing cage and press to seat them on cage shoulders. Lubricate bearings and cups with light oil and install rear bearing on pinion shank and insert drive pinion and bearing assembly in bearing cage. Install spacer or spacer combination on pinion shank and press front bearing firmly against spacer.

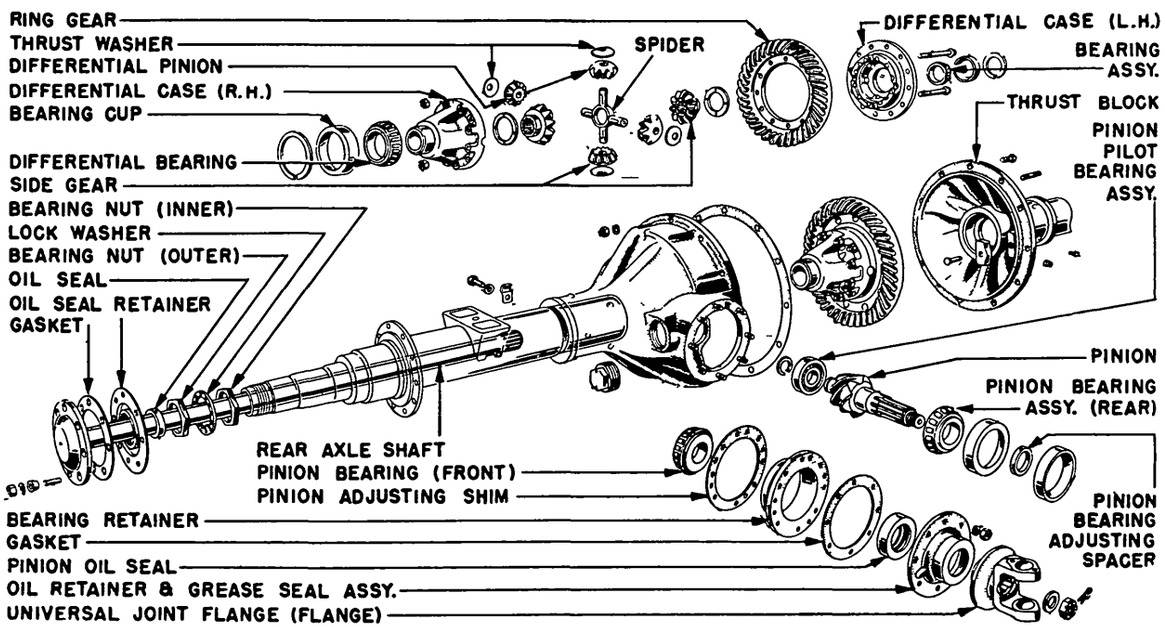
Drive Pinion Bearing Pre-Load Check—Install a sleeve on drive pinion shank that will apply pressure to pinion bearing inner race. Place pinion and cage assembly in a press and apply 25,000 lbs. pressure on the bearing. Wrap a soft wire around the cage and attach a pound-pull scale to wire. Pull on the scale on a horizontal line. It should require 12-18 inch lbs. to keep the cage rotating. If rotating torque is not between 12-18 inch lbs., install a thinner spacer to increase or a thicker spacer to decrease the pre-load. If a press is not available, the yoke may be installed and the pinion nut tightened to 300-400 ft. lbs., for checking the pre-load. After preload is checked and is satisfactory, install new oil seal in drive pinion bearing cover, using Tool 1175-D (F-6). Tool T53T-4676-B (F-350). *(NOTE—Soak new seal in oil at least one-half hour before installing).* Install drive pinion bearing cover, yoke, nut, and washer. Tighten nut to 300-400 ft. lbs. and install cotter pin.

Differential Reassembly—Position ring gear on case, making sure it is tight on case pilot. Install rivets and upset them cold. Head should be ⅛" larger than rivet hole, after forming. Formed head of rivet should be at least 1/16" smaller in diameter than performed head. Excess pressure will distort case and result in gear eccentricity. Lubricate all parts with gear lubricant. Position a thrust washer and side gear in ring gear half of differential case assembly. Place spider with the pinions and thrust washers in position on the side gear. Install remain-

CONTINUED ON NEXT PAGE

FORD TRUCK HEAVY DUTY "SPLIT HOUSING" (C ntinued)

ing side gear and thrust washer. Align marks on each half of case and place two halves together. Install the bolts and nuts and tighten to 80-110 ft. lbs. Lock nuts with lock wire. Install differential case bearings, using a press or suitable driver.



Differential Bearing Pre-Load Adjustment—Remove thrust block from housing. Install differential bearing cups and spacers in their original position in differential housing. *(CAUTION—Install spacers with chamfered edge toward machined surface in housing).* Insert pipe used in disassembly through the housing half. Place differential and gear assembly over the pipe and slide assembly into position in housing. Install new flange gasket and position the other half of housing half in place and secure the two halves together with 6 bolts evenly spaced. Install dial indicator on housing so that dial shaft extends through thrust block pin hole and contacts ring gear. Using two screw drivers, check differential assembly end play. Should be 0.000-0.005".

NOTE—Both the differential bearing pre-load and gear lash are controlled by selective spacers, available in .004" thickness, which are installed between bearing cups and axle housing halves).

It is necessary to separate the housing halves and remove the differential bearing cups each time spacer thickness is changed. The gear may be moved toward the pinion, to decrease gear lash, by decreasing spacer thickness in case half and increasing spacer thickness in cover half. Reversing this procedure will move gear away from pinion to increase gear lash. **(IMPORTANT**—Increase or decrease thickness of spacer used in COVER half of housing to obtain a free rotating gear with from .000-.005" end play. AFTER END PLAY HAS BEEN ESTABLISHED, add spacer to equal .008" **PLUS THE END PLAY).** After endplay has been established, separate axle housing and move differential assembly out on support far enough to permit installation of drive pinion and cage assembly. Install the thrust block.

Pinion Cage Installation—Position drive pinion and cage assembly on rear axle housing studs and tap cage into place with soft hammer. Install lock washers and stud nuts or capscrews. Tighten to 70-90 ft. lbs (F-6). 25-30 ft. lbs. (F-350).

Gear Backlash Check—After correct preload has been established, install six bolts evenly spaced in housing and tighten to 85-95 ft. lbs. Install a dial indicator so indicator shaft will rest on one side of universal joint yoke approximately 2" from centerline of pinion shaft. Check movement for backlash. The amount indicated at this point will be double the actual amount. Shift the spacer used in back of the differential bearing cups in axle housing, DECREASING the thickness of spacer used, on side TOWARD which gear is to be moved, and increasing the thickness of the opposite spacer EXACTLY the same amount as required to obtain a backlash of .006-.012" (dial will read .012-.024"). After correct backlash is obtained, install remaining housing bolts and tighten to 85-95 ft. lbs.

FORD TRUCK HEAVY DUTY "SPLIT HOUSING" HYPOID AXLE

FORD TRUCK HYPOID "BANJO HOUSING" TYPE

Ford Truck, 500 & 600 Series (1953-55)

►*NOTE—Different axle assemblies used for each series. Except for minor structural differences and variation in size of parts; the two axle assemblies are identical. The service procedures apply to both assemblies unless otherwise noted.*

DESCRIPTION: Full-floating, hypoid gear type with Banjo Type housing and Hotchkiss drive.

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: This work can be done without removing wheels and hubs, as follows:

Axle Shafts—Drain lubricant from housing, then remove axle shaft stud nuts and washers. Tap center of axle shaft flange to loosen tapered dowels, and remove the dowels. Remove axle shaft and gasket from housing. To install, place new gasket on hub and install axle shaft in housing, rotating axle to line up axle splines with splines in gear. Install tapered dowels, lock washers, and nuts on studs and tighten to 50-70 ft. lbs torque.

Wheel Bearing Adjustment—Remove axle shaft (above), bearing locknut and washer. Tighten wheel bearing adjusting nut while rotating wheel back and forth, until a noticeable drag is felt, then back off adjusting nut ⅛ turn. Install bearing lock washer and lock nut, and bend one tab of lock washer over adjusting nut and one tab over locknut. Install axle shafts.

►*OVERHAUL NOTE—Axle assemblies are different for the F-500 & F-600 Trucks, in parts sizes and structural variation.*

OVERHAUL (ALL 500 SERIES, 1953-54 600 SERIES): The following service procedures apply to both series trucks except where noted. *See "Overhaul (1955 600 Series)" for differences which apply to the later 600 Series Rear Axle.*

Disassembly: Remove wheels, axle shafts (see "Axle Shaft Removal" above). Remove hub and drum assemblies and brake backing plates.

Differential Carrier Removal—Support carrier assembly with a roller jack and remove carrier-to-housing nuts and lockwashers. Tighten the puller screws provided in carrier, until carrier is loosened from housing. Carefully withdraw carrier assembly from axle housing, then back off puller screws. Remove and discard axle housing gasket. Position carrier in transmission stand or on open end of oil drum, for further work.

Differential Carrier Disassembly—Loosen thrust block screw (used on Series F-500 only), then back out thrust screw to provide clearance between thrust block and ring gear, when differential is removed. Mark differential bearing caps and carrier legs to insure reassembly in same position. Remove the adjuster locks, bearing cap bolts and caps. Remove side bearing adjuster, then lift differential assembly out of carrier. Remove ring gear thrust block from carrier.

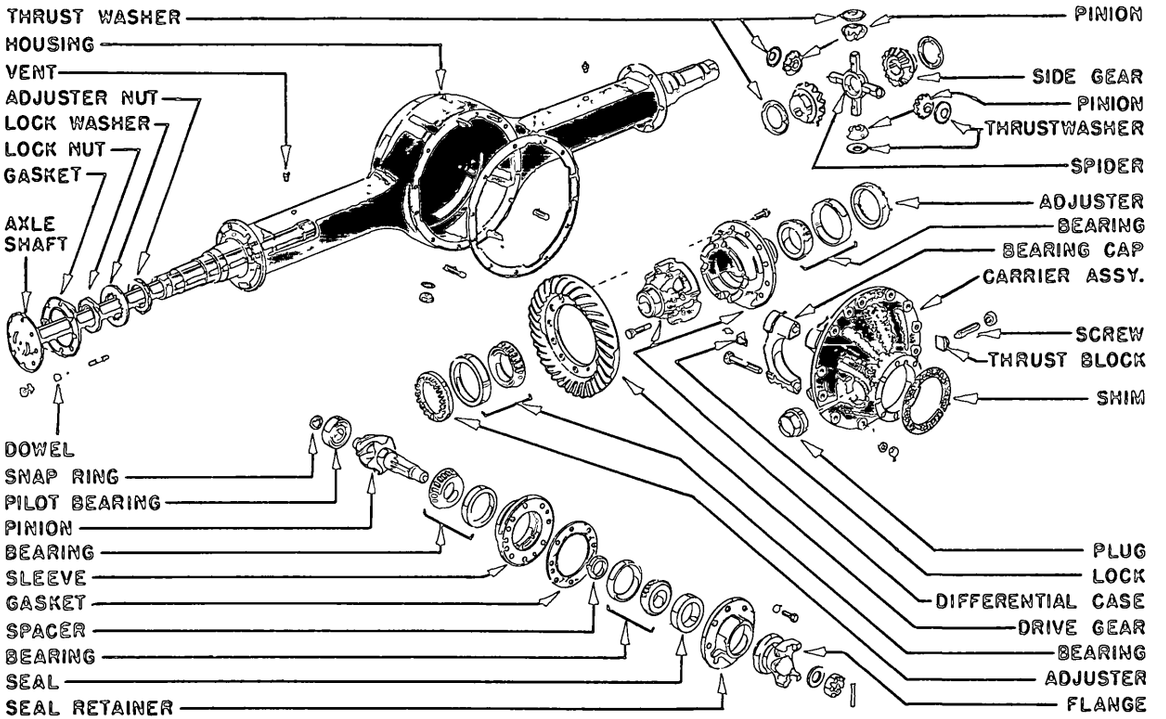
Differential Disassembly—Clamp assembly in a vise equipped with brass jaws, then remove differential side bearings. *(CAUTION—Make sure bearing cap is clamped tightly on bearing)* with Tool T53T-4242-F. Mark the differential case halves with a punch to insure aligning case when reassembling. Cut the

CONTINUED ON NEXT PAGE

FORD TRUCK HYPOID "BANJO HOUSING" (Cont.)

lock wires and remove differential case bolts and nuts (F-600), or cap screws (F-500). Separate case halves, using a brass hammer if necessary, then remove side gears, spider, pinions and thrust washers. Center punch the drive gear rivet heads and then drill through the rivet heads using a drill 1/32" smaller than rivet body. Press out the rivets, then tap drive gear off case with a soft hammer.

Drive Pinion Removal—Hold universal joint flange with Tool T53T-4851-E, then remove cotter pin, nut and washer from drive pinion shaft. Remove flange with Tool T53T-4851-A. Remove nuts or bolts and lockwashers attaching oil seal retainer and pinion bearing sleeve to differential carrier. Remove pinion and sleeve from carrier with a soft hammer.



Drive Pinion Disassembly—Remove pinion bearing sleeve shims noting quantity and thicknesses used. Remove oil seal retainer. Remove universal joint flange thrust washer (F-600). Remove front pinion bearing and spacer from sleeve. Tap or press drive pinion out of bearing sleeve. Press drive pinion rear bearing off shaft with Tool T53T-4242-F. Remove pilot bearing snap ring, then remove pilot bearing with Tool T53T-4625-A and arbor press. Remove pinion bearing cups from sleeve.

Reassembly & Adjustment: Inspect gear teeth, bearings and bearing cups for signs of galling, pitting or wear, and replace any parts found to be defective. Clean all parts and blow dry with air.

Drive Pinion Reassembly & Preload Adjustment—Press drive pinion pilot bearing on pinion, then install snap ring. Press pinion rear bearing on shaft until seated against back face of pinion gear. Press pinion bearing cups in sleeve, then insert drive pinion, and install pinion bearing spacer. Install front bearing in sleeve.

Preload Checking & Adjustment—Install a sleeve on the pinion shank that will apply pressure to pinion inner race. Place drive pinion and cage assembly in a press and apply 25,000 lbs., pressure on bearing. Wrap a soft wire around cage and attach a pound pull scale to wire. Pull on scale in a horizontal line and note pull required to keep cage rotating. If rotating torque is not between 12 to 18 inch lbs., install a thicker washer to decrease or thinner washer to increase the preload. (NOTE—If a press is not available, install the universal joint flange, tighten nut to 300-350 ft. lbs., then check the preload. After correct preload has been obtained, remove universal joint flange).

Installation in Carrier—Install a new oil seal in drive pinion bearing cover with Tool T53T-4676-B (F-500), or Tool T53T-4676-C (F-600). *(NOTE—Soak new oil seals in oil for one-half hour before installation).* Position the universal joint flange thrust washer (F-600 only), bearing cover, universal joint flange, washer and nut on drive pinion. Hold flange with holding tool and tighten nut to 300-350 ft. lbs. torque. Install cotter pin. Place the original pinion bearing shims on differential carrier, then place drive pinion and cage assembly in carrier. Tap assembly into place with soft hammer and install capscrews or nuts, and lockwashers. Tighten capscrews (F-500) to 25-30 ft. lbs., and tighten nuts (F-600) to 55-75 ft. lbs. torque.

FORD TRUCK "BANJO HOUSING" HYPOID AXLE

Differential Reassembly—Position drive gear on differential case, making sure that drive gear and differential case are clean, then rivet gear to case. Assemble pinions, side gears, spider, and thrust washers in drive gear half of differential case. Install other half of case, making sure the punch marks on case halves are aligned. Install differential case bolts and nuts (F-600) or capscrews (F-500). Tighten capscrews (F-500) to 45-50 ft. lbs., or nuts (F-600) to 95-105 ft. lbs. Install lock wires.

Differential Installation & Backlash Adjustment—Install thrust block screw in axle housing, then place thrust block on screw (F-500 only). Place side bearing cups over side bearings, then position differential assembly in carrier. Position bearing adjusters in carrier, making sure adjuster threads mesh with threads in carrier. Install bearing caps in their original position using alignment marks as guide. Tighten bearing cap bolts enough to hold adjusters snug but still permit rotation. Tighten adjusters hand tight against side bearing cups. Turn left hand adjuster until drive gear is loosely meshed with pinion gear. Mount a dial indicator so contact stem bears against back face of drive gear, then loosen right hand adjuster just enough to notice endplay on indicator. Tighten this adjuster until .000" endplay is obtained. Check drive gear runout. If runout exceeds .008" remove differential and check cause. TIGHTEN EACH ADJUSTER ONE NOTCH FROM .000" POSITION to preload differential bearings.

Backlash Adjustment—Mount dial indicator on carrier with contact stem of indicator bearing against face of one tooth on drive gear, then adjust drive gear to obtain .006-.012" backlash. To reduce the backlash, loosen right hand adjuster and tighten left hand adjuster the same number of notches. To increase, perform the same operation in reverse. Check pinion gear setting (below) and if correct, tighten bearing cap bolts to 80-100 ft. lbs. (F-500), or 120-140 ft. lbs. (F-600). Install adjuster locks, tighten lock bolts to 15-20 ft. lbs. torque, then install lock wires.

Pinion Gear Setting—Check gear tooth contact pattern by coating a number of ring gear teeth with red lead, and rotating the pinion shaft back and forth while maintaining a slight pressure on ring gear. Pressure pattern should be uniform and centered slightly toward inner side of tooth center. If adjustment is necessary, pinion position can be changed by varying thickness of shim pack between pinion cage and carrier.

Thrust Pad Adjustment (F-500)—Tighten thrust block screw until thrust block just touches drive gear. Back off screw at least 1/6 turn but not more than 1/4 turn to provide proper clearance between block and drive gear. Tighten thrust block lock screw while holding screw in this position.

CONTINUED ON NEXT PAGE

FORD TRUCK HYPOID "BANJO HOUSING" (Cont.)

Differential Carrier Installation—Place a new carrier-to-housing gasket on axle housing studs, making sure puller bolt holes in gasket are aligned with holes in housing. Place differential carrier on roller jack, then roll assembly into position. Start carrier into housing with four nuts evenly spaced. Tighten nuts alternately to draw carrier squarely into housing. Install remaining nuts and lockwashers and tighten nuts to 55-75 ft. lbs. torque.

OVERHAUL (1955 600 SERIES): Procedures for overhaul are the same as for All 500 Series and 1953-54 600 Series Rear Axles except as noted below:

Disassembly: Differential Carrier Removal—Remove rear axle housing cover and gasket, then remove differential carrier from housing.

Differential Dissassembly—Differential case halves are held together by capscrews.

Drive Pinion Disassembly—Grind peened portion off of drive pinion, then press pinion out of pilot bearing. Remove pinion bearing cup from sleeve.

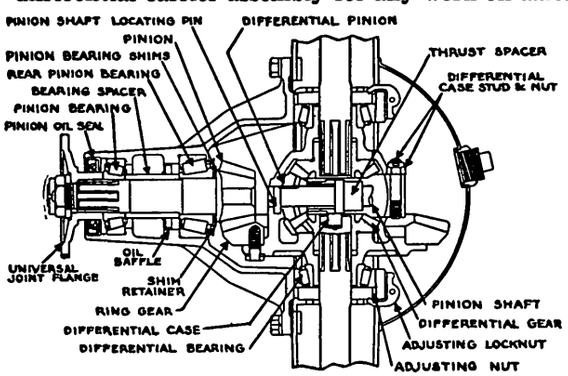
Reassembly & Adjustment: Drive Pinion Reassembly & Preload Adjustment—Press pilot bearing on drive pinion, then peen or stake end of drive pinion to secure pilot bearing in place.

Preload Checking & Adjustment—Rotating torque should be 18-25 in. lbs.

Installation in carrier—Install new felt grease seal with Tool T53T-4676-C. Make certain that gasket groove in face of pinion sleeve flange is clean, then install a new cork gasket, which has been soaked in water, in the groove. Tighten capscrews to 25-30 ft. lbs. Tighten nuts to 85-95 ft. lbs.

Differential Reassembly—Tighten differential case capscrews to 50-70 ft. lbs.

Differential Installation & Backlash Adjustment—Runout should not exceed .006".



Backlash Adjustment—Tighten bearing cap bolts to 160-175 ft. lbs.

Differential Carrier Installation—Install new cover gasket and cover with capscrews and new lockwashers. Torque capscrews to 50-70 ft. lbs.

HUDSON SPIRAL BEVEL

Six & Eight, All Models (1946-47)

DESCRIPTION: Spiral bevel, semi-floating type. Rear cover welded in place requiring removal of differential carrier assembly for any work on axle.

REMOVAL OF AXLE: *See "Rear Axle" on car model page.*

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: Check and adjust bearings whenever axle shaft is replaced.

Axle Shaft Replacement. Remove rear wheels, axle shaft nut and washer, use wheel puller to remove hub and brake drum assembly (do not use knock-out type puller). Take off 4 nuts on wheel bearing adjusting cap, remove cap and bearing adjusting shims, use puller J-352 to remove shaft and bearing assembly. Use bearing remover to remove bearing cone and rollers from shaft, and special tool to re-install bearing.

Oil Seals—Use oil seal replacer tool J-353-1 to install new oil seal in bearing adjusting cap. Use tool HM-555 to remove old seal from axle housing, and use driver J-353-2 to install new seal assembly.

Wheel Bearing Adjustment Note—When installing axle shaft (above), adjust end play by installing correct shim thickness between bearing adjusting cap and backing plate so that shaft endplay is .002-.004". Adjustment should be made equally at both wheels.

Axle Shaft Thrust Button Renewal. Thrust button consists of hardened steel plug in inner end of axle shaft. To remove button, grind end flush with shaft, center punch button and drill through center with 11/32" drill, tap hole with 3/8-16 tap, screw in 3/8-16 capscrew, place head of screw in vise and tap end of shaft with soft hammer to remove button. Drive new button into place in shaft.

OVERHAUL: Disassembly. Mark differential bearing caps and adjusting nut positions (to facilitate reassembly), remove bearing caps and lift out ring gear and differential assembly. Use special puller J-354-A to remove differential bearing cones from differential case hubs making certain that puller fingers installed in notches in case so that they engage bearing cone. Remove bolts and lockwashers to remove ring gear. To disassemble differential gears, remove cotter pins and nuts and separate right and left halves of differential case. When reassembling differential gears, select thrust washers of correct thickness so that gears have no appreciable endplay when installed (it should be possible to turn gears by hand by grasping axle shafts). Install thrust washers with smooth side toward gears and rough side toward case.

Pinion Bearing Assembly:—To disassemble pinion and bearings from carrier, remove nut and washer on end of shaft, pull rear universal joint companion flange using puller J-456, withdraw pinion, spacer, and shims through rear of carrier. Use tool J-489 to remove oil seal from carrier, lift out front bearing cone, use tool HM-63 to remove bearing cups from carrier bore. Use tool J-1301 to remove rear bearing cone from pinion shaft. When reassembling, seat bearing cups in carrier with tool J-270-H, insert front bearing cone, install new oil seal with replacer tool J-353-1 (see Note below), install pinion, spacer and adjusting shims (see Bearing Adjustment and Pinion Setting below), install companion flange and tighten nut with torque wrench to 200 ft. lbs. while holding flange with special tool J-789.

Oil Seal Note—Two types used (with concave or flat outer surface). Both types installed in same manner but clearance must be maintained between edge of dust shield on companion flange and oil seal (will cause noise if there is contact at this point).

Pinion Bearing Adjustment—Re-install same pinion bearing adjustment shims between bearing spacer and front bearing cone, tighten pinion shaft nut securely with rear universal joint flange in place, check bearing adjustment. It should be just possible to turn pinion shaft with one hand. Add thin shim if bearings too tight. Pinion bearing endplay should be .000-.001".

Pinion Setting:—When reassembling pinion install same shim thickness between pinion and rear bearing cone to retain correct pinion position. Adjust pinion by adding or removing shims at this point NOTE—Standard pinion setting shim pack thickness is .006" (all models).

Differential Bearing Adjustment:—To set up bearings when installing differential carrier, tighten differential bearing cap capscrews finger tight, turn left hand adjusting nut in until all play eliminated between pinion and ring gear, then tighten right hand adjusting nut securely. Set up dial indicator to check gear backlash, back off left hand adjusting nut one half notch and tighten right hand nut equal amount until gear backlash is .0005-.0035". Tighten bearing capscrews securely on left hand adjusting nut, turn right hand adjusting nut in one additional notch to secure correct bearing pre-load of .009" bearing tension. Tighten right hand bearing capscrews securely and install locks on both nuts.

Ring & Pinion Gear Adjustment: Paint gears to check gear mesh. Pinion position controlled by shims between pinion and rear bearing cone. Backlash should be .0005-.003". Adjusted by backing off one differential bearing adjusting nut and tightening opposite nut equally. See Pinion Setting and Differential Bearing Adjustment above.

Ring Gear Replacement:—With gear removed, runout of gear mounting flange on differential case should not exceed .002". When installing gear, see that gear and case are clean and smooth and not nicked or burred. Use lockwashers on all gear mounting screws and tighten all screws uniformly

1948-52 HUDSON HYPOID

Six & Eight, All Models (1948-52) See Production Change (following).

▷*1952 REAR AXLE PRODUCTION CHANGE: Late 1952 Cars with "Dual Range Hydra-Matic Drive" use a different axle. See "Spicer Rear Axle".*

▷REAR AXLE IDENTIFICATION: Differential case part number and axle ratio indicated by marking on right front side of carrier flange:

Model	Axle Ratio	Marking
1948-52	4 1/10-1	1-10
1948-52	4 5/9-1	5-9
1950	3 9/11-1	①9-11
1951-52	3 7/12-1	①7-12

①—See Differential Case Assembly Caution (following):

▷DIFFERENTIAL CASE ASSEMBLY CAUTION 3 9/11-1 & 3 7/12-1 RATIO REAR AXLES)—Ring gear mounting flange on these carriers is machined to .062" greater depth (to allow for greater pinion diameter on these axles) and this deeper machined carrier must be used for these two ratios only. There is a ⅛"x 1/32" chamfer on outer corner of ring gear mounting face (chamfer not found on first units).

▷PINION OIL SEAL CHANGE: Several types have been used and must be installed as unit assemblies with correct type Dirt Shield & Universal Joint Flange. See Pinion Oil Seal data.

DESCRIPTION: New semi-floating, hypoid gear, Hotchkiss drive type with separate differential carrier assembly. Carrier assembly should be removed for all work.

AXLE SHAFT REPLACEMENT: Remove rear wheel, use puller to remove wheel hub and brake drum. Take off nuts on bearing adjusting cap studs, remove cap and oil seal assembly, remove bearing shims. Pull axle shaft and bearing assembly out of housing. Use bearing remover to remove bearing cone and rollers from shaft, and special tool to reinstall bearing. Adjust bearings when re-installing

Wheel Bearing Adjustment: Shaft endplay should be .001-.004". Adjust endplay by installing correct shim thickness under bearing adjusting cap (shims furnished .003", .005", .015" thick) when replacing axle shaft. Adjust endplay equally at both wheel bearings to maintain centered position of spacer block on differential pinion shaft

REAR AXLE DISASSEMBLY & OVERHAUL: With carrier assembly removed from housing, mark both bearing caps and adjusting nuts to insure reassembly in same relative positions. Remove bearing capscrews, lift off bearing caps, remove adjusting nuts, lift differential assembly out of carrier. To remove drive pinion, remove nut on pinion shaft at universal joint flange, pull flange, remove pinion, rear bearing cone and rollers, and bearing spacer out through rear of carrier (CAUTION—Do not lose bearing shims located on shaft between spacer and front bearing cone). Remove front oil seal, lift out front bearing cone and roller assembly. Use special tools to remove bearing cups from carrier. Use puller to remove rear bearing cone and roller assembly from pinion shaft (CAUTION—Do not lose pinion adjusting shims located on shaft behind rear bearing cone)

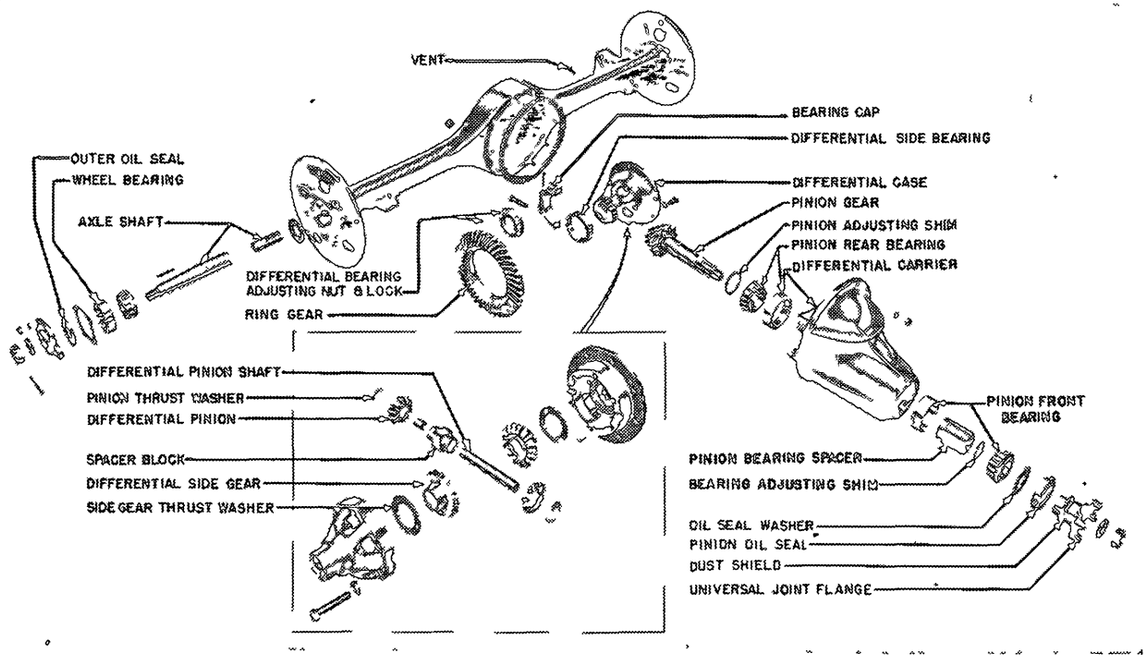
Pinion Bearing Assembly: Use special tools to seat pinion bearing cups in carrier bore. Insert bearing adjusting shims (see Pinion Bearing Adjustment below), front bearing cone and roller assembly, install oil washer and oil seal (see below). Place pinion shims on shaft (see Pinion Setting below), install rear pinion bearing cone and roller assembly using special tool to seat cone against shims, place bearing spacer on shaft, insert assembly in carrier. Install universal joint flange (with dirt shield on hub), tighten pinion shaft nut to 200 ft. lbs.

▷Pinion Oil Seal Installation—*CAUTION—Several types used.* Each type seal designed to be used with special design Dirt Shield (& Universal Joint Companion Flange) and parts should be matched when installed as follows:

Oil Seal Part No.	Dirt Shield & Flange No.
300312	161012 or 301817
301959①	301817 or 300308
303843	303842

①—This seal can be used with new type 303842 Dirt Shield & Flange but is not recommended (will not provide improved sealing of new 303843 Oil Seal).

Pinion Setting: Pinion position and gear mesh controlled by shims between pinion and rear bearing cone. When re-installing pinions, make certain that same number and thickness of shims (furnished .002", .003" thick), installed at this point as were removed when axle disassembled. Adjust pinion to obtain proper tooth contact by adding or removing shims at this point.



Pinion Bearing Adjustment: Bearing pre-load controlled by shims between spacer on shaft and front bearing cone. When re-installing pinion and bearings, make certain that same number and thickness of shims (furnished .002", .003", .004" thick) installed at this point as were removed when axle disassembled. Bearing resistance torque 27-32 in. lbs. (torque required to rotate pinion shaft).

Differential Assembly: To dismantle assembly, remove ring gear capscrews, press off ring gear, take out capscrews and separate differential case halves, lift out differential side gears, pinions, thrust washers, shaft, and thrust block. Use special puller to remove side bearing cone and rollers. When reassembling, see that ring gear seat on case is clean and free from burrs, use internal-tooth lockwashers on mounting screws, tighten screws evenly to 50 foot lbs. torque. Install brass thrust washer behind each differential pinion, see that locating pin in shaft engages hole in case and that thrust block in place on center of shaft. Install bakelite thrust washer behind each side gear (these washers control backlash and are furnished .031", .036", .041", .046", .051", .056" thick for selective fit). Use special driver to install differential side bearing cone and rollers.

▷NOTE—Ring gear should be heated in water to approx. 200°F. to facilitate installation.

Differential Bearing Adjustment & Ring Gear Backlash: When installing differential assembly in carrier, install adjusting nuts and bearing caps according to previous markings, tighten bearing capscrews finger tight. Turn left hand adjusting nut in until all backlash between ring and pinion gears is taken up, then tighten right hand adjusting nut tight. Set up dial indicator to check backlash, back off left hand adjusting nut and tighten right hand nut equally until correct backlash of .004-.006" is secured. Tighten left hand bearing cap screws to 55-65 ft. lbs. Turn right hand adjusting nut in one full notch to provide necessary .008-.012" spread for correct bearing pre-load, tighten bearing cap screws to 55-65 ft. lbs., install adjusting nut locks.

Carrier Assembly Installation: Tighten carrier to axle housing nuts to 35-40 ft. lbs.

1948-52 HUDSON HYPOID REAR AXLE

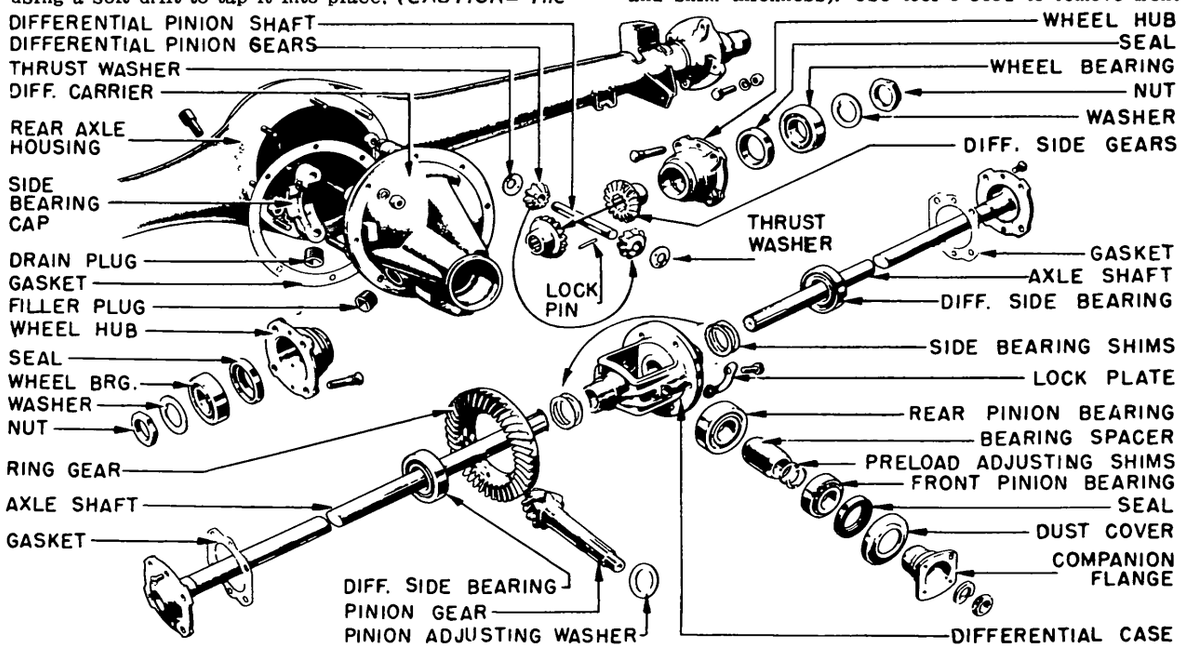
METROPOLITAN (NASH & HUDSON) HYPOID

Metr p litan, Nash & Huds n Mod ls (1954-55)

DESCRIPTION: Three-Quarter floating, hypoid gear, Hotchkiss drive, with separate differential carrier.

REMOVAL OF AXLE: *Carrier assembly or complete axle assembly can be removed as follows:*

Carrier Assembly–Raise rear end of car, drain axle housing and remove axle shafts (see Axle Shaft Removal). Disconnect propeller shaft at rear universal companion flange and remove shaft. Remove nuts attaching carrier to housing and remove carrier.



Axle Assembly–Disconnect brake cable at balance lever and brake hose at "tee" fitting. Disconnect propeller shaft at rear universal joint companion flange and remove shaft. Disconnect rear springs by removing "U" bolts at spring seats and remove assembly from beneath car.

AXLE SHAFT REMOVAL: Raise car, drain rear axle, and remove the wheel. Release hand brake and make certain the linings are not binding on drum. Remove drum locating screw and tap drum off hub. Remove axle shaft retaining screw (counter-sunk screw between axle flange studs), and pull axle from housing.

REAR WHEEL HUB (Removal): With wheel, drum, and axle shaft removed, bend up the lockwasher tabs locking nut in position and remove nut. Remove hub with Puller J-1644-B and Thrust Block J-1644-3. The hub, ball bearing, and seal will come off as an assembly. Tap bearing and seal out of hub using a soft drift.

Installation–Install a new oil seal into position in hub with seal lip toward bearing, then install the bearing using a soft drift to tap it into place. *(CAUTION– The face of b aring outer race should protrude .001-.004" beyond face of hub with rear wheel hub gasket in place when bearing is seated in hub. This insures that bearing is correctly placed between shoulder abutment in hub and the flange of the axle shaft).* Pack bearing and hub with wheel bearing lubricant before assembling to axle housing. Install hub assembly on axle housing with tool J-2995 (Transmission Clutch Shaft Snap Ring Installer).

DISASSEMBLY (Carrier Removed From Axle Housing): Remove differential side bearings, noting that cap and housing half of bearing seat are marked with numerals to indicate correct location at reassembly. Lift differential case from carrier. Use a suitable bearing puller installed so that it pulls on inner bearing race (case is recessed to provide puller clearance). As each bearing is removed, measure the thickness of shims found between bearing and case. The thickness of these shims is determined at the factory for a .002" bearing preload and must not be changed. Mark the ring gear and case to insure assembly in the same location and tap ring gear from case with a brass drift, after removing the capscrews and lock plates. With a 1/8" diameter drift, 3" long, drive out the pinion shaft lockpin, and drive out pinion shaft. Roll differential pinions and thrust washers around on the side gears until they can be removed from case, then remove side gears. Use tool J-1412 (Companion Flange Puller) and remove flange from pinion shaft. Tap pinion shaft lightly to free front bearing cone and remove bearing. Remove pinion shaft and rear bearing as an assembly from rear of housing (note shims and spacer location and shim thickness). Use tool J-5691 to remove front bearing cup, and tool J-5690 to remove rear cup. Remove pinion rear bearing with tool J-358-1 and plate J-5550, pressing bearing off pinion in an arbor press. Remove adjusting washer found between bearing and gear.

METR P LITAN HYPOID REAR AXLE ASSEMBLY

REASSEMBLY: Before reassembling, inspect all parts for wear, nicks, burrs, and cracks. Replace defective or damaged parts.

Differential Case Reassembly: Install side gears in bores of case. Install the thrust washers behind differential pinion gears and mesh the gears with pinion gears so the holes are opposite and in line with each other. Roll the gears around until gear holes are aligned with holes in differential case and install pinion on the pinion shaft with the lock pin hole in line with lock pin hole in differential. Install ring gear on case, aligning the marks made at disassembly. Make sure that face of gear and face of case are clean and that there are no nicks or burrs on either that would prevent gear seating on case. Install attaching capscrews and lock plates, tightening screws evenly in a diagonal pattern to 28-30 ft. lbs. torque. Check ring gear runout before locking the capscrews with the lock plates.

Ring Gear Run-out Check–Place differential case in a set of "vee" blocks or in carrier (with side bearings installed) and check runout with a dial indicator in in position against face of gear. Runout should not exceed .002". If greater, remove gear from case and check face of case. If this runout exceeds .002", replace differential case. If runout is indicated in the ring gear, replace ring gear and pinion as a set.

Side Bearing Installation–Replace original shim pack under their respective bearings (as noted at disassembly), and install side bearings with tool J-2995, making sure that side of bearings marked "Thrust" is toward outside of case. *CAUTION–The shim pack behind th side bearings is predetermined at th factory to provide a .002" preload and it is v ry important that th total shim pack not be changed. Adjustment of shims from one side to the other for ring gear backlash can b made as indicated in "Backlash Adjustment" b low.*

Pinion Shaft Reassembly & Installati n: Install pinion bearing cups in carrier housing as follows: Center rear cup in bore and install tool J-5559-10, install front cup and install tool J-5559-11. These tools will seat in inner angles of cups. Insert tool J-5559 through the cup and tool assembly and draw cups down into bores until cups are seated on shoulders in bore. Check to make sure that cups are properly seated. (If new ring gear & pinion is being installed, see "Pinion Depth Adjustment" below), proceed as follows: Install pinion depth adjusting washer on pinion shaft next to gear (use the same washer as removed or a new one of the same thickness). Install bearing with large diameter toward gear, pressing it into place with tool J-1416. Make sure it is tight against washer and gear. Install pinion shaft shim pack (controls pinion bearing preload), and spacer on pinion shaft and install the assembly in housing. Install front bearing tapping it into place. Install companion flange with tool J-1375 (do not install oil seal at this time). Check pinion bearing preload (see below) and adjust as necessary. Remove pinion shaft

CONTINUED ON NEXT PAGE

METROPOLITAN (NASH & HUDSON) HYPOID (Continued)

nut and install oil seal, then install lock washer and nut and tighten nut to 140-150 ft. lbs. torque.

Pinion Depth Adjustment: (Without Nash Tool J-2499)—Note the inspection marks on the old and new piston gears and measure the thickness of the old depth adjustment washer (located between rear bearing and pinion gear). Install a new depth washer of correct thickness to compensate for any differences between inspection marks on old and new pinion gear. As an example: If old pinion is marked "minus 2", and the newgear is marked "plus 2", there is a difference of .004" in the two pinion gears. Therefore, the new depth adjustment washer must be .004" thicker than the old one. Depth adjustment washers are furnished in sizes from .116" to .130" in .002" variations.

Pinion Depth Adjustment: (With Nash Tool J-2499)—Place rear pinion bearing cone in cup. Press the cone and revolve it to set the rollers. Bolt gauge plate over bearing so that it does not touch housing at any point (the bolt runs down through bearing and is secured at forward end of housing with a cross-piece and thumb screw). Install dial indicator to tool J-2499, with indicator button on gauge pin. Set dial indicator to "zero" under tension. Install tool with correct size adapters squarely seated in the side bearing bores in housing. Swing gauge point across plate until the highest reading is obtained. This reading subtracted from the constant of .140" will give the standard adjustment washer thickness for that housing. Using this figure, add or subtract according to the marking on the pinion to determine correct adjustment washer. For example: If a gauge reading of .014" obtained, subtracting this figure from .140" will give a standard of .126". This means using a standard "O" pinion, an adjusting washer of .126" would be required. However, if a pinion marking reads "minus 2", the .002" must be subtracted from the .126" which would mean an adjusting washer of .124" is required.

Pinion Bearing Preload Adjustment: With pinion shaft assembly installed (including preload adjusting shim pack and spacer found at disassembly), install companion flange and pinion nut and tighten nut to 140-150 ft. lbs. (do not install seal). Place carrier assembly in in a vertical position and using a socket wrench to fit the pinion nut and a "tee" handle, measure the amount of pull required to rotate the pinion by attaching a spring scale to "tee" handle at a point 4" from center of pinion shaft. Note the reading on the spring scale as the pinion starts to move, and multiply this reading by four to determine the inch pounds required to turn shaft. The specified bearing preload is 12 to 14 inch pounds *(NOTE—This setting supersedes the previous setting of 3 to 4 inch pounds).* Adjust the preload by removing or inserting shims between pinion bearing spacer and the front pinion bearing.

Differential Case Installation in Carrier: Install differential case assembly in carrier bearing seats and install the bearing caps (note that caps are stamped on one side, and when installing, this stamp should be on same side as corresponding stamp on leg of carrier housing bearing seat). Tighten bearing cap stud nut to 50-55 ft. lbs. torque.

Ring Gear & Pinion Backlash Adjustment: *(CAUTION—Gear backlash should be .005" to .008". The recommended backlash for each individual ring gear and pinion set is etched on the back face of the ring gear).* Measure the backlash with a dial indicator mounted so the indicator button is against a tooth of the ring gear. Rock the ring gear with the pinion held stationary and note the amount of movement. Adjust the backlash by moving one or more shims located behind side bearings, from one side to the other *(CAUTION—Do not change thickness of TOTAL bearing shim pack as predetermined at factory to provide .002" bearing preload).*

Carrier Assembly Installation: Reverse the removal procedure and torque the stud nuts to 30 ft. lbs.

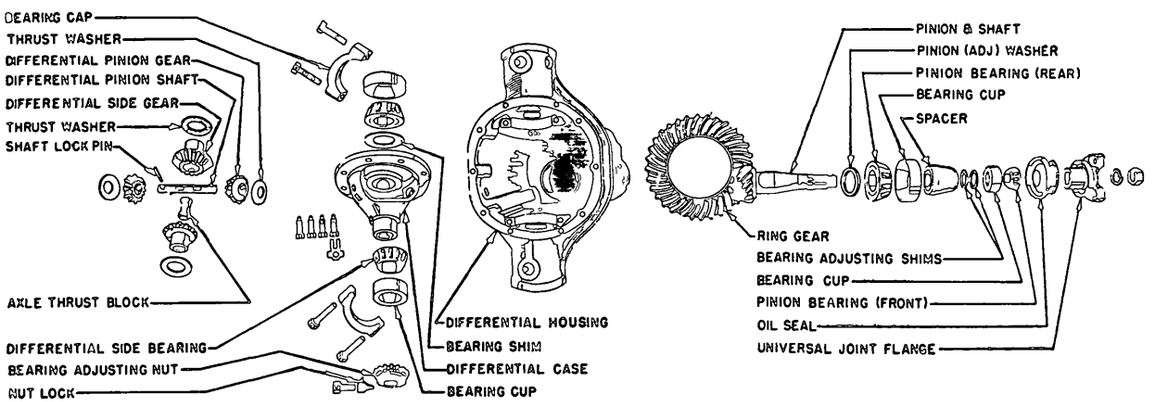
1946-48 NASH AMBASSADOR HYPOID

Nash Ambassador Six. All Models (1946-48)

▷REAR AXLE IDENTIFICATION TAG: Ring & pinion gear ratio stamped on tag attached to axle by one of differential housing cover bolts.

▷*CAUTION—Tag should be kept with axle parts and reinstalled when axle reassembled. Install new tag when gear ratios changed (tag furnished with gears).*

DESCRIPTION: Hypoid gear, semi-floating type with Hotchkiss drive. Pinion and shaft mounted on taper roller bearings seated directly in housing with spacer on shaft between bearing cones. Shims for bearing adjustment located between spacer and front bearing cone, washer for pinion setting adjustment between pinion and rear bearing cone. Differential assembly mounted on taper roller bearings seated directly in housing with adjusting nut at right hand bearing cap only (shims installed between left bearing cup and housing for backlash adjustment).



REMOVAL OF AXLE: *See "Rear Axle" on car model page.*

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: To remove axle shaft after the wheel and hub removed, take off nuts on bearing retainer (rear brake support plate), remove oil seal, retainer plate, bearing adjusting shims, then pull axle shaft and bearing assembly. When installing shaft, add or remove shims between retainer plate and axle housing flange to secure desired axle shaft endplay of .002-.004". When installing shafts, bearing cup should be allowed to project slightly so that cup will be properly located by brake support plate as it is tightened in place. NOTE—Cars are assembled at factory with .046" shim thickness between right axle tube and brake support plate, and sufficient shim thickness on left side for desired axle shaft endplay of .002-.004". This allows endplay adjustment to be made at each wheel.

OVERHAUL: Disassembly. With axle shafts out, remove rear housing cover, mark adjusting nut on right hand differential side bearing to insure replacing in same position, back adjusting nut off, remove bearing cap bolts and bearing caps, lift differential assembly out. To remove pinion, remove nut on end of pinion shaft, pull universal joint flange using puller J-1412. Remove pinion shaft oil seal (discard seal and install new seal when reassembling axle). Tap end of pinion shaft with soft hammer to loosen front bearing cone, remove bearing cone and roller assembly, remove shims located behind bearing cone, note number and thickness of these shims which control bearing adjustment. Remove pinion and rear bearing assembly through rear of housing. Use long drift to drive pinion bearing cups from housing (recess provided behind each cup for this purpose). Use pinion bearing tool J-2245 to remove rear bearing from pinion shaft, note number and thickness of washer or shims on shaft behind bearing which control pinion setting (gear mesh). To remove differential side bearing cone and roller assemblies, use special puller J-2497 being careful that puller does not contact roller cage or damage shims in back of left hand bearing (these shims control ring and pinion gear backlash).

Pinion Bearing Assembly:—Bearing adjustment controlled by shims located on pinion shaft between spacer and forward bearing cone. When installing pinion, install correct washer and shim pack for

CONTINUED ON NEXT PAGE

NASH HYPOID GEAR AXLE (HOTCHKISS DRIVE)

1946-48 NASH AMBASSADOR HYPOID (Cont.)

correct pinion mesh (see Pinion Setting below) on shaft against pinion, install rear bearing cone and bearing spacer. Install sufficient shims on shaft in front of spacer to insure positive endplay of shaft when installed in housing, install front bearing cone, universal joint companion flange, or special tool (splined sleeve) and tighten nut on shaft securely. Then check bearing adjustment as directed below. NOTE—Do not install oil seal until after bearing adjustment has been made.

Pinion Bearing Adjustment: Use a dial indicator to check pinion shaft endplay with companion flange nut securely tightened (oscillate shaft in both directions while applying end pressure to insure bearings seated). Disassemble pinion shaft and remove shims from between spacer and front bearing cone equal to the observed endplay **plus .003"** to insure correct bearing pre-load or set (.003" tight).

Pinion Bearing Pre-Load Adjustment with Tool J-2496: With pinion installed in axle housing (make certain that spacer and bearing adjusting shims in place on shaft between bearing cones), install tool on end of shaft in place of universal joint flange, tighten pinion shaft nut securely. Attach spring scale to exact center of tool handle (will provide 6" arm), check torque required to turn pinion shaft. Desired torque is 15-18 in. lbs. (spring scale reading x 6) for .003" bearing pre-load. If less than 15 in. lbs., **remove** shims from between spacer and front bearing cone; if more than 18 in. lbs., **add** shims at this point. When bearing adjustment completed, install new oil seal using Tool J-1556, install universal joint companion flange using Tool J-1375, tighten pinion shaft nut to 105-110 ft. lbs.

Pinion Setting Without Gauge—If new pinion being installed and pinion setting gauge not available, note washer and shim thickness used for old pinion, secure standard washer thickness for this housing by adding (if pinion marked +), subtracting (if pinion marked —) shims equal to figure following this plus or minus mark on the old pinion, finally correct this standard washer thickness in accordance with new pinion marking as directed under Pinion Setting above.

Pinion Setting using Rear Axle Drive Pinion Gauge No. J-2499: With rear pinion bearing cup installed in housing, place bearing cone and roller assembly in cup, press in and revolve bearing cone so that rollers are properly seated. Bolt special gauge plate on bearing cone (thread bolt through housing and secure in place with cross-piece and thumbnut at forward end), make certain **that gauge plate does not contact housing** at any point. Mount dial indicator on tool with indicator button on top of gauge pin, set dial indicator at "0" with tension on gauge pin. Install tool in housing with **larger** diameter of adapter rings seated in side bearing seats (install adapters on tool with larger diameter rings outward). Swing gauge point across gauge plate and note highest reading of dial indicator, **subtract this** on end), add (if pinion marked —), or subtract (if **reading from .140"** and resulting figure will be washer thickness required for a standard "0" pinion. If pinion is not standard (marked by — or + figure pinion marked +) from the standard washer thickness an amount equal in thousandths to the figure following this — or + sign.

Differential Bearing Assembly: Use special puller J-2497 to remove bearing cone and roller assemblies from differential case. Note number and thickness of shims located behind left hand bearing cone (these shims control ring and pinion gear backlash). When installing bearings, make certain that same number and thickness of shims installed behind left hand bearing as were removed (place thickest shims against case), do not install any shims behind right hand bearing.

Differential Gear Assembly—To disassemble the differential gear assembly, drive out pin in differential pinion shaft, remove shaft, axle shaft thrust block, pinions, side gears and thrust washers. When reassembling, make certain that thrust washers installed in back of each side gear and pinion and that thrust block is installed on pinion shaft (this block transmits thrust from one shaft to the other).

►*CAUTION*—Always use new thrust washers for side gears and pinions. Install washers with oil pocket (pitted side) toward gears.

Differential Bearing Adjustment:—With lock on right hand bearing adjusting nut removed, and bearing cap loosened so that adjusting nut can be turned, turn adjusting nut up until all bearing endplay is just removed and notch on nut is in line with lock on bearing cap, then tighten adjusting nut **additional 1-2 notches** so that correct bearing pre-load of .004-.006" is secured. Tighten bearing cap screws to 105-110 ft. lbs., install adjusting nut lock. Recheck ring and pinion gear backlash.

Ring & Pinion Gear Adjustment: Gear mesh should be correct if pinion setting properly made (see above). Check gear tooth contact by painting gears. Check backlash as follows:

Ring Gear Backlash Adjustment—Check backlash with dial indicator at several points around ring gear. If backlash not within limits of .004-.006", dismantle axle, remove left hand differential side bearing, add or remove shims on hub behind bearing (add shims to decrease backlash, remove shims to increase backlash), reassemble axle, readjust differential bearings.

HUDSON & NASH REAR SUSPENSION

Nash "600", All Series (1946-49)
Nash Statesman (1950-55)
Nash Ambassador (1949-55)
Hudson Wasp & Hornet (1955)

►*1946-48 AMBASSADOR & 1950-55 RAMBLER NOTE:* Rear suspension on these models is conventional type with leaf type springs and Hotchkiss drive.

DESCRIPTION: Special coil spring type with springs insulated by rubber cushions at top (in body) and at lower end (at spring seat on axle housing). Direct acting shock absorbers are mounted within springs and Stabilizer is used to maintain alignment.

REMOVAL OF SPRING & SHOCK ABSORBER: Lift rear of body until all weight removed from springs, remove two nuts on shock absorber bolts at rear axle. Lift rear of body sufficiently to free shock absorber bolts from axle housing, remove lower spring saddle. Swing spring, shock absorber, and lower spring seat to one side, lower spring and lift out. To remove shock absorber after spring removed, remove nuts and rubber grommets on upper mounting stud within body, lower shock absorber and remove from below.

INSTALLATION OF SPRING & SHOCK ABSORBER: Install grommets and nuts on upper end of shock absorber in body, assemble bolts, bushings and spacer on lower end of shock absorber. Install upper rubber cushion on spring by placing projection or tab on cushion between stationary end coil of spring and first movable coil and rotating cushion until flat end of stationary coil is tight against shoulder of tapered projection on spring (CAUTION—positioning necessary to prevent contact between first closed coils of spring in operation). Install lower spring cushion similarly.

SPRINGS: Springs are ground flat at upper and lower ends. Same type springs used on all models.

Rear Spring Specifications

	Free Height	Load Height
1946-49 All (Std.)	16¾"	① 9 13/16"
1950-51 Statsmn.(Std.)	16¾"	① 9 13/16"
1950-51 Amb. (Std.)	17 7/8"	① 10 9/16"
1952-54 All (Std.)	17 7/8"	① 10 9/16"
1955 All Models (Standard)		
Less Wheel Carrier	17 7/8"	① 10 9/16"
With Wheel Carrier	17 7/8"	② 10 7/16"

1955 Heavy Duty	16 3/4" min.	① 11 1/4"

①—With load of 870 lbs. ± 25 lbs.
②—With load of 940 lbs. ± 25 lbs.

►*NOTE*—When heavy duty rear springs are installed, heavy duty shock absorbers must be installed in both front and rear.

1946-54 NASH HYPOID

Nash "600" Series (1946-49)
Nash Rambler & Statesman (1950-54)
Nash Ambassador (1949-54)

►**REAR AXLE IDENTIFICATION TAG:** Ring and pinion gear ratio stamped on tag attached to axle housing by one differential housing cover bolt.

►***CAUTION—Tag should be kept with axle parts and re-installed when axle reassembled. Install new tag (furnished with gear sets) when axle ratios changed.***

►CHANGES, CAUTIONS, CORRECTIONS

►*1952-53 RAMBLER AXLE HOUSING ASSEMBLY REPLACEMENT CAUTION*—Rear Axle Housing, Part No. 3113924 is being supplied for service replacement for all cars (Std. O.D. & Hydra-Matic), and Rear Axle Assemblies, Part Nos. 3112932 and 3114542 (Std. & O.D. Equipped cars) on cars built after Serial Nos. Kenosha D-99819 and El Segundo DC-7584. When installing above parts it may be necessary to remove shock mounting stud boss to provide room for shock absorber.

►*1953 STATESMAN PROPELLER SHAFT COUPLING PRODUCTION CHANGE—"Slip-Type" coupling replaces "Lock-nut Type" formerly used. New type coupling can be used on all Series 40 cars (1941-53).*

►**1951 AMBASSADOR DIFFERENTIAL SIDE BEARING ADJUSTMENT PRODUCTION CHANGE:** Effective with car serial No. R-601152 (11-39 ratio), R-601349 (9-40 ratio) and R-606549 (10-41 ratio) side bearing adjusting nut has been eliminated. Adjustment is now made in same manner as Statesman & Rambler Rear Axles.

►**1950-51 PINION SHAFT PRODUCTION CHANGE:** Effective with following car serial Nos. Statesman K-376736 (8-35 ratio), K-380141 (8-39 ratio), Ambassador R-607425 (11-39 ratio), R-610875 (9-40 ratio), and R-619089 (10-41 ratio), a new type pinion gear is used. Pinion bearing spacer has been eliminated. *See "Pinion Bearing Preload Adjustment"*

►**1950 REAR AXLE VENT PRODUCTION CHANGE:** Rear axle is now vented by a .067" diameter hole located on rear side of rear axle tube. Previous vent was under rear spring seat. ***Where there is evidence of water entering previous type axle, seal the hole with body sealer around spring locating pin, drill a new hole in rear side of tube approx 8⅞" from brake backing plate. Use No. 51 drill.***

►**1950 DIFFERENTIAL CAP SCREW LOCK WIRES ELIMINATED:** Wires have been replaced by shakeproof lock washers.

►**1951 HYDRA-MATIC CARS PROPELLER SHAFT:** Beginning with 1951 production a solid one-piece shaft is used and the center-bearing is eliminated.

DESCRIPTION: Semi-floating, hypoid gear, Torque Tube Drive with Coil Springs (All Models except Rambler), Hotchkiss Drive with Semi-elliptical springs (Rambler).

Universal Joint Spring ("600" & Statesman)—Coil spring backed by welded plug in the forward end of universal joint so that spring engages end of transmission driveshaft and assures correct location of universal joint. This spring must be in place when universal joint and propeller shaft assembly is installed.

AXLE REMOVAL: *See "Rear Axle" on car model page.*

PROPELLER SHAFT (RAMBLER): **Removal**—Loosen coupling nut on rear end of rear universal joint yoke, use soft hammer to tap universal joint and propeller shaft off pinion shaft.

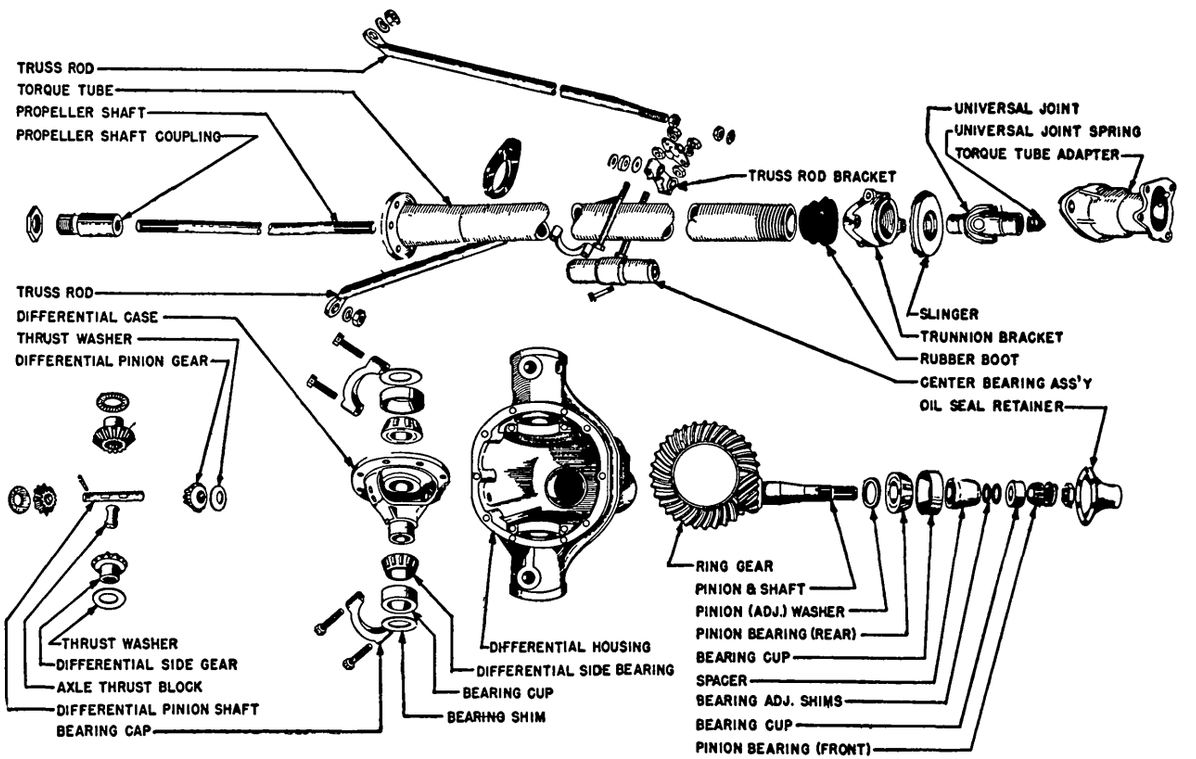
Installation Caution—Make certain that universal joint yoke lined up with pinion shaft when tapping yoke on shaft, tighten coupling nut securely.

►*RAMBLER 108" WHEELBASE MODEL PROPELLER SHAFT REMOVAL & DISASSEMBLY:* **(Removal)**—Remove propeller shaft coupling nut from coupling and tap coupling off pinion shaft with a soft hammer. Remove nuts from propeller shaft center bearing retainer studs and disconnect cross member from support brackets at side rail. Remove cross member and propeller shafts from car.

TORQUE TUBE & PROPELLER SHAFT (EXCEPT RAMBLER): These units not same design on all models.

"600" & Statesman—(Exc. Statesman with Overdrive & Hydra-Matic)—Torque tube drive type with rear end of propeller shaft connected to drive pinion ("600" & 1950-Early 1953 Statesman) by coupling and nut, and by a "Slip-Type" coupling (Late 1953). A single propeller shaft bearing (Bushing Assembly on 1941-48 "600") is used.

Statesman & 1949 "600"—(Overdrive Trans.)—Same as for synchro-mesh cars except that **two propeller shaft bearings used.**



Statesman (Hydra-Matic)—Torque tube drive type with rear end of propeller shaft connected to drive pinion by flange type coupling (same as Ambassador). No propeller shaft center bearing used.

Ambassador (All Models)—Torque tube drive with propeller shaft connected to drive pinion by flange type coupling. Single propeller shaft center bearing (Exc. Hydra-Matic Drive Cars). No bearing used with Hydra-Matic Drive.

►**Center Bearing Lubrication Note**—Center bearing on 1949-53 models is prelubricated and does not require servicing. 1941-48 "600" Models have a bushing assembly requiring lubrication every 5000 miles as follows: Take out locating screw at top side of upper clamp on torque tube at front end of truss rods, fill with light engine oil to overflowing in screw hole, replace screw and wire in place. ***CAUTION—Do not turn propeller shaft or rear wheels with bearing locating screw removed (bearing assembly will move out of place).***

Removal: (All Models)—Disconnect truss rods at center bracket ("600" & Statesman); center bracket and axle housing (Ambassador). Pry universal joint off forward end of propeller shaft (joint is light press fit). Disconnect torque tube from rear

CONTINUED ON NEXT PAGE

NASH "600" HYPOID GEAR AXLE (TORQUE TUBE DRIVE)

1946-54 NASH HYPOID (C nt.)

axle housing, move tube forward to expose shaft coupling, loosen coupling nut or remove bolts from coupling flange, and lift off torque tube and propeller shaft.

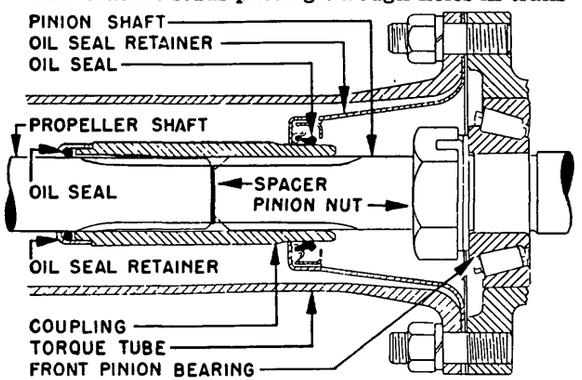
Propeller Shaft Center Bearing (Not used On All Models): Prelubricated type ball bearing retained on propeller shaft by snap ring on each side and rubber mounted in torque tube. To remove bearing take out snap ring, drive bearing off **toward front end** of shaft (forward end of shaft .003" undersize to facilitate removal & installation). Install new bearing in same manner and see that new snap rings properly seated to hold bearing in position.

Propeller Shaft Coupling Installation ("600" & Statesman "Coupling & Nut Type"): When assembling propeller shaft to pinion shaft, align both shafts and **support propeller shaft for its full length to maintain this alignment** while coupling nut is being tightened. Tighten coupling nut to 250-300 ft. lbs. torque.

►*1953 STATESMAN PROPELLER SHAFT COUPLING PRODUCTION CHANGE—A new "Slip-Type" coupling is used on Synchro-mesh or Overdrive equipped cars (See Illustration).*

►**1946-54 "600" & Statesman Propeller Shaft Coupling Service Replacement**—New type coupling can be used for service replacement on these cars (see Installation procedure below and note the Replacement Caution).

Propeller Shaft Coupling Installation (All "600" & Statesman Models with "Slip-Type" Coupling): Install propeller shaft oil seal Part No. 3138146, on propeller shaft. Butt the propeller shaft at forward end against a wood block and drive the coupling Part No. 3138142 on propeller shaft with a lead or soft face hammer. Tap retainer and oil seal on coupling (CAUTION—Do not install seal and retainer on coupling prior to its installation on propeller shaft as seal will be damaged). Coupling must be driven on propeller shaft to the shoulder or splined area inside coupling. Install Spacer, Part No. 3138466. Install torque tube rear oil seal Part No. 3138166, and retainer Part No. 3138144. Propeller shaft with coupling can now be installed on pinion shaft. Lubricate ground surface on coupling and torque tube rear oil seal with rear axle lubricant. DO NOT CRIMP LIP OF SEAL.



►*SLIP TYPE COUPLING REPLACEMENT CAUTION (EARLIER MODELS)—If pinion shaft spline is slightly worn, DO NOT REPLACE ORIGINAL COUPLING WITH "SLIP-TYPE" COUPLING.*

Torque Tube Trunnion Bracket ("600" & Statesman): On front end of torque tube and must be properly installed and adjusted when rear axle installed on car as follows:

Trunnion Bracket Adjustment—With axle completely assembled (rear end of propeller shaft against pinion shaft, torque tube assembled on housing), position trunnion bracket on torque tube so that front end of propeller shaft projects ⅛" to ¼" beyond the face of trunnion bracket. After bracket properly positioned, adjust clampscrew on underside of bracket to remove all excess clearance between threads on bracket and tube without setting up excessive friction. Bracket must be free to move on threaded tube. Lock clampscrew nut with cotter pin. Rubber boot must be installed behind bracket to protect threads on tube from road dirt. Threaded parts require no lubrication except at time of assembly. Lubricate these parts sparingly.

►*CAUTION—If propeller shaft extends less than ⅛" beyond face of trunnion bracket, universal joint slinger may rub on bracket. If shaft extends more than ¼", effectiveness of slinger will be reduced.*

Trunnion Bracket Installation on Car: After bracket position adjusted (above), torque tube and rear axle assembly can be assembled to transmission as follows: Thread 2 special trunnion bracket studs (with tapered ends to rear) on trunnion bracket and lock with nuts and lock washers. Assemble plain stamped steel retainer, rubber cushion block (with small extension to front), steel retainer with pilot flange over extension on rubber block, on each stud. Install torque tube and rear axle assembly with trunnion bracket studs passing through holes in transmission (or overdrive) rear bearing retainer. Assemble steel retainer with pilot flange to rear, rubber block with extension to rear, and plain steel retainer on front end of studs. Tighten retainer nuts on studs until rubber cushions held under slight tension. Lock nuts with 'palnuts'.

STATESMAN "SLIP TYPE" PROPELLER SHAFT COUPLING

REAR AXLE OVERHAUL: With torque tube and propeller shaft removed (see above), use stand to support axle and proceed as follows:

Disassembly: On Ambassador models (1949 through Early 1950), one differential adjusting nut is used (right hand side), and adjusting nut should be backed off before differential assembly is removed. On other models no adjusting nut is provided and the differential assembly is positioned in axle housing by shims between differential bearing cup and housing at each side. To disassemble differential, mark bearing caps to insure correct reassembly, remove bearing caps, pry differential assembly out using care not to damage bearings or shims. When reassembling, place bearing cups and shims in position on bearings, tilt bearing cups slightly so that they enter seat in housing, force assembly into place in housing which will cause bearing cups to straighten on bearing rollers. If shims project, tap shims into place, install bearing cups and tighten bolts securely.

Pinion Bearing Disassembly: Before pinion shaft can be removed, propeller shaft must be disconnected by loosening coupling nut on rear end of shaft. Then remove the oil seal from housing, bend back lip of pinion nut locking plate, loosen nut. On Ambassador models, remove nut on forward end of pinion shaft at coupling flange, pull coupling flange from shaft, lift off oil seal (held in place by torque tube flange).

Pinion Disassembly—Tap on pinion shaft with soft hammer to loosen front bearing cone, remove bearing cone and roller assembly, remove shims located behind bearing cone, **note number and thickness of these shims** which control bearing adjustment. Remove pinion and rear bearing assembly through rear of housing. Use long drift to drive pinion bearing cups from housing (recess provided behind each cup for this purpose). Use pinion bearing tool J-2244 (600 & Statesman), tool J-2245 (all Amb. models) to remove rear bearing from pinion shaft, **note number and thickness of washer or shims on shaft behind bearing** which control pinion setting (gear mesh). To remove differential side bearing cone and roller assemblies, use special puller J-2497 being careful that puller does not contact roller cage or damage shims in back of left hand bearing (these shims control ring and pinion gear backlash).

Pinion Bearing Reassembly: Assemble each model as follows:

Rambler—Install pinion, shims, and rear bearing) through rear of housing, then install bearing adjusting shims (same thickness as were removed when axle disassembled) and front bearing on forward end of shaft. Install bearing washer and pinion nut but **do not install oil seal,** tighten pinion nut to 90-95 ft. lbs. Check and adjust bearing pre-load. After bearing adjustment completed, lock pinion nut to prevent loosening, install oil seal (use installer J-4485).

All Models except Rambler—Bearing adjustment controlled by shims on the pinion shaft between spacer and forward cone (A production change in late 1950 eliminated the spacer. Shims are placed between front bearing and shoulder on pinion shaft). When installing pinion, install correct washer and shim pack for correct pinion mesh (see Pinion Setting below) on shaft against pinion, install rear bearing cone and bearing spacer. Install sufficient shims on shaft in front of spacer (or against shoulder) to insure positive endplay of shaft when installed in housing, install front bearing cone, shaft coupling flange (Ambassador) or special tool (splined sleeve) and tighten nut on shaft securely. Then check bearing adjustment as directed below. NOTE—Do not install oil seal until adjustment has been made.

Pinion Bearing Pre-load Adjustment:

Rambler Bearing Pre-load—Pre-load controlled by shims on pinion shaft behind front bearing cone. use **two** shims only, varying thickness of each shim to secure total thickness of..106" to .138" for correct .003" tight bearing adjustment and 12-14 in. lbs. pre-load. If pre-load less than 12 in. lbs., decrease shim thickness. If pre-load greater than 14 in. lbs., increase shim thickness.

►**Bearing Adjusting Shim Note**—These shims furnished in following thicknesses (combination of two shims provide range of .106" to .138" in .001" steps): .053", .054", .056", .058", .059", .063", .064", .066", .068", .069".

All Models exc. Rambler Bearing Pre-load (Tool J-2496: With pinion installed in axle housing (make certain that spacer and bearing adjusting shims in place on shaft between bearing cones), install tool on end of shaft in place of the coupling flange,

CONTINUED ON NEXT PA E

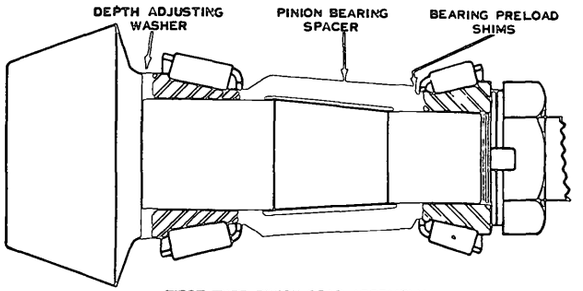
1946-54 NASH HYPOID (Cont.)

tighten pinion shaft nut securely. Attach spring scale to exact center of tool handle (will provide 6" arm), check torque required to turn pinion shaft. See table below for desired torque reading. If less than lower figure, remove shims from between spacer and front bearing cone, if greater than higher figure, add shims at this same point. When bearing adjustment completed, install new oil seal, install coupling flange (Ambassador), see that pinion nut tightened to 105-110 ft. lbs.

Pinion Bearing Pre-load

Model	Pinion Shaft Turning Torque
Rambler & Statesman	12-14 in. lbs.
Ambassador (Early type)	15-18 in. lbs.
Ambassador (Late type)	15-20 in. lbs.

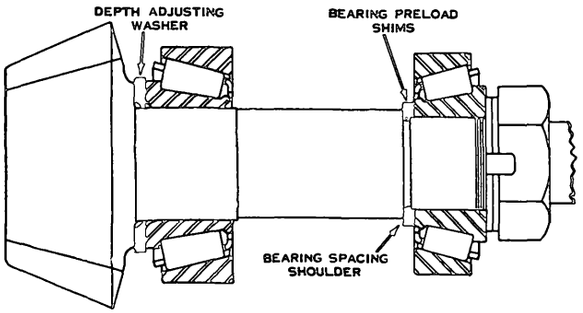
Pinion Setting: Pinion depth and consequent ring and pinion gear mesh is controlled by spacer washer or shims installed on pinion shaft between rear bearing cone and pinion. Must be adjusted when new gears or other parts installed.



Pinion Setting without Gauge—If new pinion being installed and pinion setting gauge not available, note washer and shim thickness used for old pinion, secure standard washer thickness for this housing by adding (if pinion marked +), subtracting (if pinion marked —) shims equal to figure following this plus or minus mark on the old pinion, finally correct this standard washer thickness in accordance with new pinion marking as directed under Pinion Setting above.

Pinion Setting using Rear Axle Drive Pinion Gauge No. J-2499: With rear pinion bearing cup installed in housing, place bearing cone and roller assembly in cup, press in and revolve bearing cone so that rollers are properly seated. Bolt special gauge plate on bearing cone (thread bolt through housing and secure in place with cross-piece and thumbnut at forward end), make certain that gauge plate does not contact housing at any point. Mount dial indicator on tool with indicator button on top of gauge pin, set dial indicator at Zero with tension on gauge pin. Install tool in axle housing with larger diameter of adapter rings seated in side bearing seats (install adapters on tool with larger diameter rings outward for Ambassador, small diameter outward for 600). Swing gauge point across gauge plate and note highest reading of dial indicator, subtract this reading from .140" and resulting figure will be washer thickness required for a standard "0" pinion. If pinion is not standard (marked by — or + figure on end), add (if pinion marked —), or subtract (if pinion marked +) from the standard washer thickness an amount equal in thousandths to the figure following this — or + sign.

Differential Disassembly: Use Puller Tool J-2497 to remove bearing cone and roller assemblies from differential case. Note number and thickness of shims located behind each bearing cone. These shims control ring and pinion gear backlash and differential bearing preload. Remove capscrews attaching ring gear to differential case (be sure and mark ring gear and case to retain same location when reassembled). Using a brass drift, tap ring gear from case. (CAUTION—Do not chisel or wedge ring gear from case). Use a 3/16" diameter drift at least 3" long to drive out the lock pin holding differential pinion shaft in place. Pinion shaft can then be removed, and the thrust block can then be dropped out through differential side gear. Roll differential pinion gears around on side gears until they can be lifted out through holes in case, then lift out side gears and thrust washers.



Inspection: Clean all parts and blow dry with air. Check gears for worn, cracked, chipped, or scuffed teeth. Check thrust washers and oil seal surfaces for wear or roughness, and check bearings for roughness or wear. Replace defective parts.

Differential Reassembly: Install thrust washers on side gears, with oil pocket toward gear, and install

FIRST TYPE PINION GEAR ASSEMBLY

NASH PINION GEAR ASSEMBLY
(EARLY TYPE WITH SPACER)

NASH PINION GEAR ASSEMBLY
(LATE TYPE WITHOUT SPACER)

gears in bores of differential case. Install thrust washers behind differential pinion gears and mesh gears with side gears so the holes are opposite and in line with each other. Roll gears around until gear holes are aligned with differential pinion shaft hole in case. Install pinion gear shaft with the lock pin hole in line with the lock pin hole in differential case. Before pressing differential pinion shaft in place, install the thrust block through side gear, aligning hole in block with differential pinion shaft. Press differential pinion shaft in place and measure the clearance between differential side gear and case. This clearance should not be more than .010" (side gears should not fit tight enough to require more than 8 ft. lbs. to turn differential gears). Check by installing on axle shaft and using a torque wrench to turn shaft. Drive lock pin in place. Press differential side bearings on case using Tool J-2104 (Ambassador); J-2100 (Statesman).

▷1951 AMBASSADOR DIFFERENTIAL SIDE BEARING ADJUSTMENT PRODUCTION CHANGE—Effective with car serial No. R-601152 (11-39 ratio), R-601349 (9-40 ratio) and R-606549 (10-41 ratio) side bearing adjusting nut has been eliminated. Adjustment is now made in same manner as Statesman & '600' rear axles.

Differential Bearing Adjustment (600, Statesman 1941 & Later, Ambassador 1950 & Later): See Note. Bearing pre-load should be .004-.006" and this is controlled by shims between the side bearing cups and axle housing at each side. To determine shim thickness, install carrier in housing with one .075" shim at each side, check endplay. If endplay noted, install next thicker shim on each side and recheck. With endplay just taken up, install .005" thicker shim on right hand side which will provide correct bearing pre-load of .004-.006". Tighten bearing cap screws to 55-60 ft. lbs. Check ring gear backlash with a dial indicator, finally check gear mesh by painting gear teeth with red lead and rotating gears.

Differential Bearing Adjusting Shim Note—These shims furnished in thicknesses of .075", .080", .085", .090", .095".

Differential Bearing Adjustment (Ambassador, Before Early 1950): Install differential assembly in housing (with correct shims in place between left hand bearing and case), install bearing caps and tighten screws to point where they just grip lock washers (right hand bearing cap must not prevent turning of adjusting nut), turn adjusting nut up until all bearing endplay has just been removed and notch on nut is in line with adjusting nut lock, then tighten adjusting nut 1-2 notches additional to provide correct bearing pre-load of .004-.006". Tighten bearing capscrews to 105-110 ft. lbs. and install adjusting nut lock.

Ring & Pinion Gear Adjustment: Gear mesh should be correct if pinion setting properly made (see above). Check gear mesh after all adjustments made by painting 8-10 teeth of ring gear with red lead and rotating gears by hand (turn pinion shaft with wrench while supplying drag on ring gear with the hand). Check backlash and adjust as follows:

Ring Gear Backlash Adjustment—Should be .004-.006". Measure with dial indicator. Adjust by adding or removing shims located between left hand differential bearing cup and housing ('600', Statesman and Late 1950 & Later Ambassador), and between bearing cone and case (Ambassador before Late 1950). On cars without adjusting nut, total shim thickness must not be changed and any shim change on left hand side must be offset by corresponding shim change on right hand side (to maintain bearing pre-load).

▷*CAUTION—Total shim thickness must not be changed when adjusting backlash (will disturb bearing adjustment).*

1955 HUDSON & NASH HYPOID

Hudson Wasp (1955)
Hudson Hornet (1955)
Nash Statesman (1955)
Nash Ambassador (1955)
Rambler (1955)

►*REAR AXLE ASSEMBLY NOTE: The assemblies used on all series cars are similar and overhaul procedures are the same except where noted.*

►*HUDSON HORNET V8 & NASH AMBASSADOR V8 PROPELLER DRIVE SHAFT NOISE CORRECTION & PRODUCTION CHANGE:* A noise developing at 58-62 MPH under light throttle pressure, either pull or coast (similar to rear axle gear noise) may be caused by drive shaft and can be corrected by installing a two piece shaft, Part No. 3145400. The later two-piece shaft replaced the former one-piece shaft in production at Car Serial V-8235 (Nash), Y-5887 (Hudson).

DESCRIPTION: Semi-floating, hypoid gear type with torque tube drive and coil springs (exc. Rambler). Hotchkiss drive and semi-eliptical springs (Rambler).

AXLE ASSEMBLY REMOVAL (Exc. Rambler): Raise and support rear of body. Disconnect hand brake cable at bellcrank and hand cable brake housing at bracket. Disconnect torque tube from transmission, rear brake hose at bracket on body floor pan, rear springs and shock absorbers from the axle tube, and the rear axle stabilizer bar at axle tube. Roll axle free from under car and disconnect truss rods, torque tube and propeller shaft from rear axle assembly.

AXLE ASSEMBLY REMOVAL (Rambler): Raise and support rear of body. Remove rear wheels and hubs, then disconnect and remove hand brake cables from brake assemblies. Remove propeller shaft using Coupling Nut Wrenches J-4486 (the coupling nut dust shield will serve as a puller to partially remove propeller shaft from rear axle pinion). Disconnect rear shocks, rear brake line on body floor pan, and rear springs from body. Remove axle and springs from under car as an assembly.

AXLE SHAFT: Removal—Remove wheel and with Rear Hub Puller J-1644-B or J-736-B attached to rear wheel hub, remove hub from axle *(CAUTION—Do not use "knock-out" type axle pullers).* Check axle shaft endplay using Endplay Checking Tool J-2092 and note endplay for use at reassembly. Remove capscrews attaching brake support plate to axle tube. Slide oil seal, support plate and shims off axle (the oil seal on Rambler Models is located between support plate and axle tube). Measure shims with a micrometer to determine amount to be used at reassembly. Attach Axle Shaft Puller J-2498-A to axle and pull shaft out of housing. Slip bearing cup off axle and press bearing cone off axle shaft.

Installation: Press axle shaft bearing onto axle shaft with small diameter of cone toward outer tapered end of shaft using Replacer J-2995. Soak new inner axle oil seal in light engine oil and install seal using Replacer J-2539. Install axle shaft, indexing splined end with differential side gears *(NOTE—Hornet & Ambassador right hand axle shaft is 1½" longer than left hand shaft).* Install outer bearing cup using Replacer J-1433-1. Install original shims onto axle with the drain holes aligned with hole in axle tube (if endplay was checked at time of disassembly and required correction, adjust the shim pack as necessary for correct axle shaft endplay of .002-.004"). Install brake support plate, spacer and oil seal (Rambler oil seal is installed behind brake support plate). Tighten support plate bolts to 50-55 ft. lbs. (Hornet & Ambassador), 30-35 lbs. (Other Series). Check and adjust axle shaft endplay (see below). Inspect wheel hub key for a snug fit in keyway of shaft and hub. *(NOTE—*On Rambler, install wheel hubs after axle assembly installed in car). Slide hub onto axle shaft aligning the keyways. Install key and press hub onto shaft. Key must be flush with hub. Install thrust washer and axle nut and tighten to 180-190 ft. lbs. (Hornet & Ambassador), 160-165 ft. lbs. (Other Series). Install cotter pins.

TORQUE TUBE & PROPELLER SHAFT (Exc. Wasp & Statesman with Standard & Overdrive Transmission): Removal—Raise and support rear end of body. Disconnect hand brake cable at equalizer and remove hand brake bellcrank assembly from torque tube. Disconnect rear stabilizer bar at rear axle tube. Remove truss rods at axle tubes and at center bracket on torque tube. Disconnect torque tube from transmission adapter and move axle assembly and tube to the rear to disengage propeller shaft from transmission. Disconnect rear of torque tube from rear axle housing and move tube forward sufficiently to expose coupling. Disconnect coupling flange and remove torque tube and propeller shaft. Remove pinion flange with Puller J-2984.

Installation—Reverse removal procedure and note the following: On Hornet & Ambassador use new locks on companion flange nut. On Wasp, support pinion from the rear while pressing on companion flange. Tighten flange nuts to 30-35 ft. lbs.

TORQUE TUBE & PROPELLER SHAFT (Wasp & Statesman with Standard & Overdrive Transmission): Removal—Raise and support rear end of body. Disconnect hand brake cable at equalizer and remove hand brake bellcrank assembly from torque tube. Disconnect rear stabilizer bar at rear axle tube. Disconnect truss rods at center bracket. Disconnect trunnion bracket from the adapter by removing rear nuts from dowel studs. Move torque tube and rear axle to rear to clear studs. Disconnect torque tube from rear axle housing and move tube forward. The coupling is a slip fit on the pinion shaft and a press fit on the propeller shaft. Slide coupling off pinion shaft. Place propeller shaft in a vise and drive coupling off shaft with a lead hammer.

Installation—Reverse removal procedure and note the following: Install propeller shaft oil seal and retainer on propeller shaft. Butt propeller shaft at forward end against a wood block and drive the coupling on the shaft with a lead hammer. *(CAUTION—*Do not install the seal and retainer on the coupling prior to its installation on the propeller shaft). Coupling must be driven on shaft to the shoulder on the splined area inside coupling. Install the spacer. Lubricate the ground surface on the coupling and the torque tube rear oil seal with rear axle lubricant. The propeller shaft with coupling can now be installed on pinion shaft (do not crimp lip of oil seal). Make sure that the torque tube seal contacts coupling on the ground surface of coupling.

PROPELLER SHAFT (Rambler 100" Wheelbase & 108" Wheelbase with Hydramatic): Removal—Raise and support rear of body at the side sills and the rear axle at center of housing. Loosen propeller shaft coupling using Propeller Shaft Coupling Wrenches J-4486. Disconnect rear shocks at the axle tubes, hand brake cable at adjusting yoke, and rear brake hose clip from body floor pan. Remove rear spring front bracket attaching nuts and lower the rear axle, continuing to support the body, thus lowering rear spring front brackets from the floor pan. Move axle assembly to the rear sliding propeller shaft yoke of transmission main shaft splines. Remove propeller shaft from pinion shaft.

Installation—To permit correct location of propeller shaft when assembling on the car, slide shaft onto transmission main shaft until it is bottomed. Mark propeller shaft front yoke adjacent to the oil seal and remove shaft. Install propeller shaft on rear axle pinion shaft. Move rear axle assembly to rear and slide the front universal joint yoke onto transmission main shaft. Loosen rear spring front eye bolt and tilt front bracket so that rear holes are aligned with studs in floor pan. Raise rear axle assembly aligning rear spring front bracket with studs, and tighten. Reinstall brake hose clip, hand brake cable, and rear shocks. Permit rear axle assembly to hang freely, the shocks fully extended, and move the shaft to the front or rear to locate the mark on the propeller shaft 5/32" to rear of transmission oil seal. Tighten propeller shaft coupling nut to 300 ft. lbs.

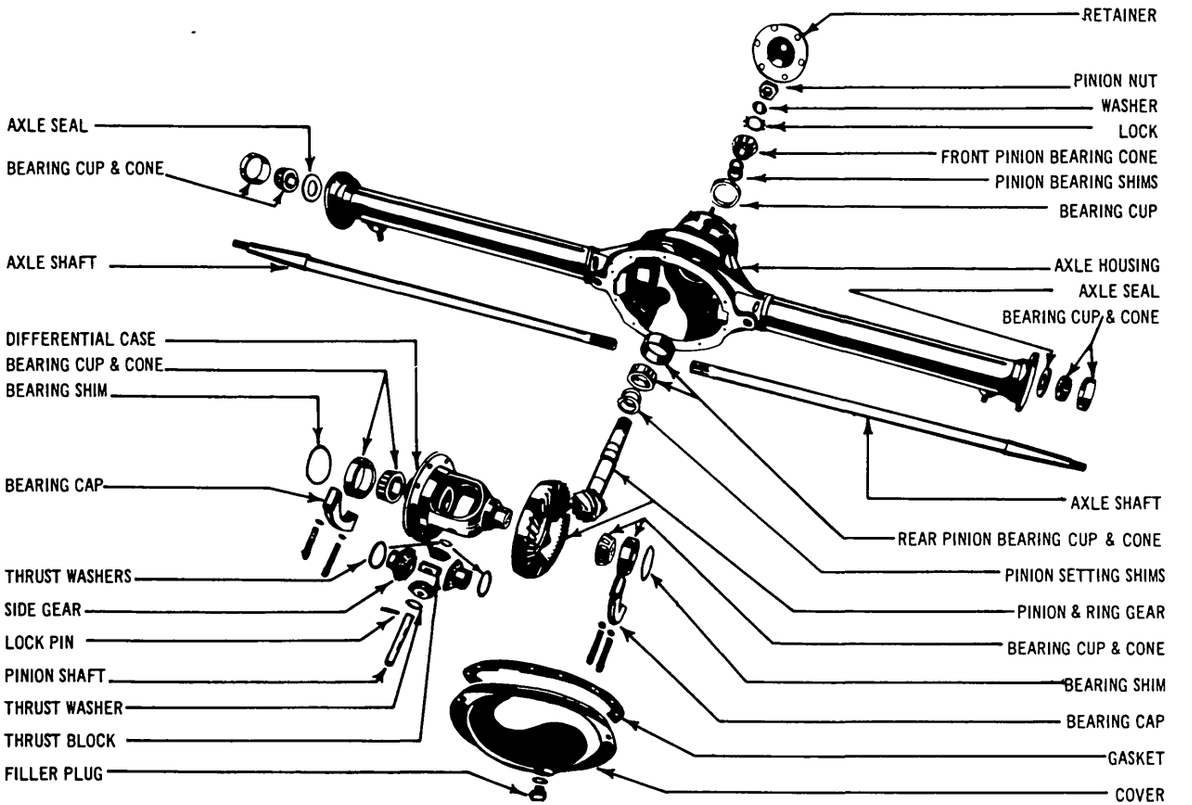
PROPELLER SHAFT (Rambler 108" Wheelbase with Standard & Overdrive Transmission): Removal—Remove propeller shaft coupling nut from coupling and tap coupling off pinion shaft splines with a soft faced hammer. Remove nuts from propeller shaft center bearing retainer studs. Disconnect crossmember from support brackets at side sills and remove crossmember. Remove assembly from car. Place propeller shaft in a vise and turn back propeller shaft bearing lock to allow propeller shaft center locknut to be removed. The rear shaft can now be removed by sliding the splined slip joint from front propeller shaft, (the locknut will remain on splined slip joint). Remove felt washer and felt washer retainers, and remove the nut. Remove propeller shaft center bearing spacer, cover, center bearing and retainer, bearing cover, and dust shield. Remove center bearing from retainer with a brass drift.

Installation—Reverse removal procedure and note the following: Yokes of universal joints must be in alignment when installed.

TORQUE TUBE TRUNNION BRACKET ADJUSTMENT (Wasp & Statesman): Tighten trunnion bracket clampscrew enough to remove excess clearance without setting up friction and so trunnion bracket is free to move on torque tube. When rear end of propeller shaft is against pinion shaft and torque tube is secured to axle housing, the front end of the propeller shaft must protrude from 1/8" to 1/4" beyond front face of trunnion bracket (except Hydra-Matic Drive models). On Hydra-Matic Drive models, adjust trunnion bracket so forward edge of dust shield is in alignment with centerline of universal joint bearing cups. Connect bracket bolts to transmission adapter.

CONTINUED ON NEXT PAGE

1955 HUDSON & NASH (Cont.)



REAR AXLE OVERHAUL: With rear axle assembly removed from car and with axle shafts removed, proceed as follows:

Diff rential Removal & Disassembly: Remove cover bolts (note ratio tag on one of bolts which should be retained for installation after overhaul), mark differential side bearing caps with a center punch to assure correct reassembly, and remove bearing caps from housing. With a pry bar inserted from each side of differential case adjacent to pinions, pry against housing and lift case assembly out. *(CAUTION–*Take care to prevent damage to bearings and shims). Tie side bearing shims to their respective bearing caps and cups to prevent misplacement. Install Bearing Puller J-2497 on bearings in such a manner as to leave rollers free, and remove bearings from case. Remove capscrews attaching ring gear to differential case, and using a brass drift, tap ring gear from case. *(CAUTION–Do not chisel or wedge the ring gear from case).* Use a 3/16" diameter drift at least 3" long to drive out the lock pin holding differential pinion shaft in place. Drive out pinion shaft, dropping the thrust block out through differential side gear. Roll differential pinion gears around on side gears until they can be lifted out through holes in case, then lift out side gears and thrust washers.

Insp cti n–Inspect all parts for distortion, cracks, and excessive wear. Inspect all bearing surfaces for nicks and burrs and dress down small nicks or burrs with a smooth file or stone. Check fit of differential pinion shaft in case. Shaft should be a press fit to .010" loose. Inspect fit of differential side gears in differential case bore. This clearance should not exceed .007". Clearance between side gear and case should be .000" to .008" with .004" preferred. Where differential assembly is a tight fit, it will be acceptable if not more than 8 ft. lbs. of torque applied to either side gear will rotate the internal gears. If gears need replacement, pinion and side gears should be replaced as a set. Inspect ring gear and if tooth pattern indicates pinion and ring gear have not been meshing correctly, replace both gears. Inspect ring gear attaching bolts for elongation and replace any bolts that are defective.

Pini n Shaft R moval & Disassembly: Remove companion flange or coupling from pinion shaft (see "Torque Tube & Propeller Shaft" above). Tap end of pinion shaft slightly with a fibre hammer to free front bearing cone from pinion shaft and remove bearing. Retain shim located between bearing and shoulder on pinion shaft (this shim controls bearing preload) and tag it for use at reassembly. Remove pinion and shaft assembly from rear of housing. Drive bearing cups out of rear axle housing using a drift inserted in recess in housing. Keep cups square in the bore to prevent damaging bores. Remove rear bearing from pinion shaft using Pinion Bearing Remover J-2245-A (Hornet & Ambassadore), J-2244 (Wasp, Statesman & Rambler) and an arbor press. Remove pinion bearing adjusting washer located between bearing and pinion gear. Tag and retain this washer for use at reassembly (washer is used to adjust pinion depth in housing).

Insp cti n–Check to see that ring gear and pinion are matched sets (numbers or marks are etched in rear face of pinion gear and the edge of ring gear). Inspect oil seal surface for wear or roughness and pinion splines for damage caused by worn or loose coupling. Inspect pinion gear teeth. Inspect bearings, cones, cups and rollers for excessive wear, overheating, or scoring. If replacement required replace bearing cone and cup.

HUDSON & NASH HYPOID REAR AXLE

Differential Reassembly & Side Bearing Adjustment: Install new thrust washers on side gears with oil pockets on washer toward gear, and install gears in bores of differential case. Install new thrust washers behind differential pinion gears and mesh gears with side gears so holes are opposite and in line with each other. Roll gears around until gear holes are aligned with differential pinion shaft holes in case. Install pinion gear shaft with the lock pin hole in line with lock pin hole in case, partially into case. Install thrust block through side gear, aligning hole in block with pinion shaft. Press pinion shaft into place and measure clearance between differential side gear and case. This clearance should not exceed .008". (see "Differential Inspection" above to check tightness of side gears). Drive lock pin into place to secure pinion shaft. Press differential side bearings into place on case using Side Bearing Replacer J-2646 (Hornet & Ambassador), J-5364 and handle J-875-5 (Other models). Place bearing cup over each side bearing and install differential case assembly in axle housing (ring gear not installed on case and drive pinion not installed in housing). Install a .070" shim (Hornet & Ambassador), .075" shim (Other Series) on each side between bearing cup and housing. Test assembly for side play by rotating it, and install progressively greater shims to eliminate all side play. Hornet & Ambassador Series shims are available in thicknesses from .070" to .100" in .002" increments. Other Series are available in thicknesses from .075" to .098' in .002" increments. *(NOTE–*If additional thickness of shims is required to eliminate side play on Hornet & Ambassador, thin shims .003", .005", or .010" may be installed between bearing cone and differential case. For other series, use Hornet & Ambassador pinion depth adjusting shims in the same manner). When side play is eliminated, a slight bearing drag is noted. Install respective bearing caps and tighten cap bolts to 105-110 ft. lbs., (Hornet & Ambassador), 55-60 ft. lbs., (Other Models). Recheck differential for excessive bearing drag. Attach a dial indicator to axle housing and check ring gear face of differential case for runout. Runout should not exceed .002'. Remove

CONTINUED ON NEXT PAGE

1955 HUDSON & NASH (C nt.)

case from housing, **retaining shims used to liminate side play.** Install ring gear on differential case and bolt gear to case with capscrews and new locks. If necessary, two 3/8"-24X1" capscrews installed in opposite holes may be used as guides to pull gear into position. Tighten capscrews to 50-55 ft. lbs. and install locks.

Pinion Shaft Reassembly & Installation: Install rear bearing cup in axle housing with Installer J-2533 (Hornet & Wasp), J-5367 (Other Series). Install front bearing cup with Installer J-2531 (Hornet & Ambassador), J-2532 (Other Series), being careful to drive all bearing cups straight into clean bores. Slide proper depth washer and new shims that have been selected (if old pinion and ring gear being reinstalled, use same washer and shims pack found under rear bearing at time of removal. If a new pinion and ring gear or new bearings being installed, adjust pinion depth as indicated below. *See "Pinion Setting").* Use bearing Installer J-2995 (Wasp, Statesman, Rambler) and press bearing tight against washer and gear. On Hornet & Ambassador, a piece of steel tubing 1 11/16" I.D. about 8" long may be used to install pinion gear assembly in housing. Install same thickness of shims as removed and install front bearing. If adjusting washer thickness was changed, add the necessary shims to compensate for the change. On Hornet & Ambassador use pinion holding and spacer tool J-2496 and install spacer in place of the companion flange. Tighten pinion nut to 125-150 ft. lbs. On other series, install pinion nut, thrust washer, and lockwasher. Tighten nut to 90-100 ft. lbs. Adjust pinion bearing preload as indicated below.

Pinion Bearing Preload: Install Pinion Holding Tool & Spacer J-2496 on pinion shaft. Attach a spring scale to center of handle and pull tool in a circular motion. Note reading on scale and multiply it by six to determine the inch pounds of torque required to rotate pinion shaft *(NOTE*—For a more accurate reading, turn axle up so pulling effort is on a horizontal plane). Pinion bearing preload is 15-18 inch pounds (Hornet & Ambassador), 12-14 inch pounds (Other Series). If preload is too high, **increase** shim thickness behind front bearing. If too low, **decrease shim thickness.** Complete installation as indicated below.

Hornet & Ambassador—Remove spacer tool and install a new oil seal. Install companion flange using Tool J-1375. Install lockwasher and pinion nut and tighten to 125-150 ft. lbs.

Wasp, Statesman & Rambler (Exc. Wasp with Hydra-Matic)— Install lockwasher next to bearing then the plain washer and nut. Tighten nut to 90-100 ft. lbs. Install pinion oil seal on Wasp and Statesman. Use Tool J-4485 to install pinion oil seal on Rambler.

Wasp (With Hydra-Matic)—Press pinion shaft companion flange onto pinion shaft while supporting shaft from the rear to prevent damage to bearings or axle housing.

►*PINION BEARING PRELOAD ADJUSTING SHIM NOTE:* A thickness range of .106" to .138" in .001" increments can be obtained by using a combination of two of the following size shims which are supplied for service installation. .053", .054", .056", .058", .059", .063", .064", .066", .068", .069".

Pinion Setting (With Pinion Setting Gauge J-2499): Place rear pinion bearing cone in bearing cup and revolve it using a little pressure to "set" the rollers. Bolt gauge plate over bearing cone so that it does not touch housing at any point (the bolt runs down through housing and is secured at pinion end). Attach a dial indicator to tool. With indicator button on top of the gauge pin, set dial indicator, under tension, to zero. Install tool with adapter squarely seated in side bearing bores in housing (Large diameter of adapter is used for Hornet & Ambassador, and small diameter is used for other models). Swing gauge point across plate until highest reading is obtained. This reading subtracted from a constant of .140" will give the standard adjusting washer thickness for that particular housing. Using this figure, add or subtract according to marking on pinion to determine correct adjusting washer thickness. For example: When gauge point is moved across plate and a reading of .015" is obtained, subtracting this figure from the constant of .140" will give a standard of .125". That means, using a standard "O" pinion, and adjusting washer of .125" thickness would be required. However, if pinion marking read -3 (meaning that it is .003" away from ring gear) it would be necessary to **add** this .003" to the standard. Thus the adjusting washer and shim combination would be .128".

Pinion Setting (Without Pinion Setting Gauge): Note pinion marking on old pinion and new pinion gears and measure the thickness of the old depth washer and shims. Compensate for the difference in the old and new pinion markings and correct the depth washer and shim thickness. As an example: If old pinion is marked +2 and the new pinion is marked -3, there is a difference of .005" (indicating new pinion .005" further away from ring gear than old pinion). If old washer is .123", the new washer and shim pack must be .128". In In this case use a .125" washer and a .003" shim.

Ring Gear & Pinion Backlash Adjustment: Install differential assembly in housing using the shims selected to remove side play (see above). Tighten bearing caps to 105-110 ft. lbs. (Hornet & Ambassador), 55-60 ft. lbs. (Other Series). Attach a dial indicator to housing with the button contacting drive side of a tooth on ring gear and at right angles to it. "Rock" the ring gear and note dial reading. The backlash should be .002-.006" (.004" preferred). To increase backlash, install a thinner shim on ring gear side and a thicker shim on opposite side. To decrease backlash, reverse the procedure. *(CAUTION—Total thickness of shim pack must not be changed from those selected to remove all sideplay).*

Differential Side Bearing Preload: Increase shim pack (selected to remove sideplay) by adding a .004" to .008" thicker shim. These additional shims can be installed on one side only, or divided equally and installed on both sides.

Differential Assembly Installation: Assemble side bearing cups and shims on side bearings (make sure that bearing cups completely cover rollers of side bearings). Lower assembly into axle housing until bottom edge of bearing cups and shims are started in bearing bore. Keep differential assembly square in housing and push it down as far as possible. Using a soft hammer, tap outer edge of bearing cups until seated in housing *(CAUTION—Do not distort shims by hammering them into housing).* Install bearing caps and tighten to 105-110 ft. lbs. (Hornet & Ambassador), 55-60 ft. lbs. (Other Series). Recheck ring gear and pinion backlash and correct as necessary. Coat eight or ten teeth of ring gear with red lead in oil and check tooth contact pattern. *See "Hypoid Gear Adjustment" in Manual.* Install axle shafts, *see "Axle Shafts" above.*

AXLE ASSEMBLY INSTALLATION: *See "Torque Tube & Propeller Shaft" and "Axle Assembly Removal" above and reverse the removal procedures outlined.*

OLDSMOBILE HYPOID

Six & Eight, All Models (1947-55)

►CHANGES, CAUTIONS, CORRECTIONS

►*1953 PINION BEARING SPACER PRODUCTION CHANGE:* A new spacer that cannot become "cocked" during installation is used in production, replacing the former type. Later type spacer **cannot** be used for service replacement of first type spacer.

►*1953 & LATER PEDESTAL CAP SPREADING GAUGE CAUTION:* 1953 and Later Rear Axle Assemblies require a new gauge, Tool J-5340. DO NOT USE GAUGE SUPPLIED FOR PREVIOUS MODELS.

►*1949 & LATER "PILOTED" DIFFERENTIAL CARRIERS & AXLE HOUSINGS—(All Eight Cyl. Models & Six Cyl. Models using 3.9-1 ratio Rear Axle Assemblies)* —Except for machined pilot surfaces on pedestal caps, all differential carrier assemblies are alike, and the piloted carriers will fit into non-piloted housings, however, **non-piloted carriers cannot be installed in piloted housings** because of interference between housing supports and the non-machined pedestal caps. *CAUTION*—Only housings with welded supports and carriers with machined pedestal caps can be used on all eight cylinder models and on 6 cylinder models with 3.9-1 rear axle ratios.

►***CARRIER & HOUSING INSTALLATION CAUTION: On all cars with "Piloted" type carrier and housing, special differential side bearing adjustment and carrier installation procedure required. See data below.***

►**PINION BEARING PRE-LOAD CAUTION: Pinion bearing pre-load must be adjusted whenever universal joint companion flange nut on pinion shaft loosened (pre-load controlled by this nut and will be disturbed when nut loosened for any reason).**

►**DIFFERENTIAL GEAR THRUST WASHER CHANGE (Installation of 1950 Washers on previous cars): New Parco-lubricated metal thrustwashers as used on 1950 cars should be installed to replace previous type fiber washers whenever axles being rebuilt. These new washers furnished Standard & Oversize as Part No. 513714 (Side Gear Washer), No. 500517 (Pinion Washer).**

►**PINION BEARING SPACER SERVICE REPLACE-**

CONTINUED N NEXT PAGE

OLDSMOBILE HYPOID (Cont.)

MENT—Two piece type spacer furnished for service replacement. Two piece spacer consists of spacer & collar, and is installed with collar toward front pinion bearing.

AXLE IDENTIFICATION (1947-49): Number stamped on upper surface of differential carrier (1947); on under side of carrier housing at right horizontal bottom rib (beginning 1948) indicates ratio (number of teeth in ring & pinion gear) as follows: 39:10 (3.9-1 ratio), 40:11 (3.64-1 ratio), 41:9 (4.56-1 ratio), 41:10 (4.1-1 ratio), 41:12 (3.42-1 ratio), 42:13 (3.23-1 ratio), 43:10 (4.3-1 ratio).

1950-55—Rear axle ratios and date of manufacture stamped on underside of differential housing. First digit designates ratio (see table below), second digit designates month ("A" for January, "B" for February, etc.). Last digit is year ("0"—1950 etc.).

Code	Ratio	Code	Ratio
0	3.07-1 (40-13)	4	3.90-1 (39-10)
1	5.55-1 (41-9)	6	3.64-1 (40-11)
2	4.30-1 (43-10)	8	3.42-1 (41-12)
3	4.10-1 (41-10)	9	3.23-1 (42-13)

Piloted Axle Housing Identification—Housing with pedestal cap supports (welded on inner face of carrier mounting flange on each side) must only be used with special piloted carrier (with machined bearing caps).

DESCRIPTION: Semi-floating hypoid gear type of same design used on previous models except for new adjustable pinion bearing mounting:

Pinion Shaft & Bearings—Pinion mounted on taper roller bearings (front and rear) and bearings are adjustable by tightening universal joint companion flange nut (see Servicing data below). Front and rear bearing cups are seated against shoulders in carrier housing and a compressible spacer is used on the pinion shaft between the bearing cones. Pinion position is adjusted by means of shims between rear bearing cup and carrier (standard shim thickness changed from previous models).

▷1949-50 Axle Design Changes

Carrier Assembly Mounting Capscrews—Increased to 7/16" (were 3/8") and must be tightened to torque of 40-45 ft.lbs. NOTE—New gasket, No. 556042, with larger bolt holes must be used.

Pedestal Bearing Cap Screw Lockwashers—NO lockwashers used beginning 1949 (to insure more permanent setting of capscrews). Screws should be tightened to 70-75 ft. lbs. torque.

▷1953 Axle Design Changes—Axle assembly has heavier construction than previous type and adjustment specifications are different.

REMOVAL OF AXLE: *See Rear Axle on car model page.*

PINION SHAFT OIL SEAL RENEWAL (Without Disassembly of Rear Axle): Mark pinion shaft nut before loosening it and retighten to exact same position after oil seal installed (see oil seal data below). This will avoid necessity of resetting the pinion bearing pre-load. If new companion flange being installed, see Pinion Bearing Pre-load Adjustment Oil Seal Installation—Always install new oil seal (old seal will be damaged by removal). Lubricate seal leather with oil and coat outer diameter of seal with Permatex No. 3 or similar sealer, tap seal in place in housing bore using Driver J-5395.

AXLE SHAFT REPLACEMENT: Wheel bearings not adjustable (ball bearings). Replace shafts as follows:

Axle Shaft Removal—Remove wheel and brake drum, remove nuts from four bolts attaching brake backing plate on axle housing, use puller J-492 to withdraw axle shaft and bearing assembly.

▷*CAUTION—Use care not to dislodge backing plate which will damage brake line, or to drag shaft on oil seal which will damage or distort seal.*

Wheel Bearing Note—New wheel bearings are built with .012-.015" endplay between balls and races and should not be rejected unless endplay is greater than .020" or there is definite roughness between ball and race.

Wheel Bearings & Oil Seal. Bearings are shielded type (lubricated at factory) and pressed on axle shaft against shoulder at wheel end of shaft. Remove bearings only when new bearings installed (see Bearing Collar Note below). To remove, use tool J-947-2 (to prevent bursting of race), and plate J-947-1 and press bearing off shaft in arbor press. Install new bearings in same manner using tool J-947-3 and plate J-947-1 to insure pressure being applied to inner race only. Before installing shaft, make certain that double feather edge of leather oil seal is in good condition or install new seal (See Installation Note below). Coat outer rim of seal with Permatex or white lead to prevent oil leaks between seal and housing.

Bearing Collar Note—On all models, collar is installed on shaft behind bearing. Collar must be split with chisel before bearing removed. After new bearing installed, press new collar on shaft firmly against bearing with tapered end toward bearing.

Rear Axle Shaft Oil Seal Installation—Install seal using Tool J-5818 to insure seal being driven in squarely and to proper depth. *NOTE*—An adapter is provided with this tool for use on 1954 and earlier rear axle shaft oil seal installation.

▷IMPORTANT SERVICE CAUTION: Pinion bearing pre-load is controlled by universal joint companion flange nut on pinion shaft and bearing adjustment will be disturbed when this nut is loosened. Pinion bearings must be adjusted each time companion flange nut is disturbed.

DISASSEMBLY: With rear axle removed from car, remove axle shaft, take out mounting screws and remove carrier assembly. Disassemble carrier assembly as follows: Mark differential bearing caps and adjusting nuts to insure reassembling parts in same relative positions and to same settings. Remove the differential bearing caps and adjuster nuts, lift differential case and ring gear assembly out. Remove universal joint companion flange nut (use holding tool J-2933 and 1" socket wrench 1947-52, tool J-5293 and 1¼" socket wrench 1953 and later), pull companion flange with tool J-962 (and adapter J-5294 1953 and later) taking care that pinion does not fall out. Remove the pinion through rear of the carrier using care not to damage shaft threads or oil seal (if pinion does not slide out, tap pinion out with a soft hammer, or press pinion out in an arbor press), lift compressible spacer and shim from pinion shaft. (NOTE—On some cars, a shim .037-.045" thick may be found between spacer and front bearing cone, this shim must be re-installed if same spacer used when axle reassembled). Remove oil seal, lift front bearing cone and roller assembly out. Press front and rear bearing cups out of housing in an arbor press (use Front Pinion Bearing Race Remover J-2938 & Removable Handle J-2940; Rear Pinion Bearing Race Remover J-2936 & Removable Handle J-2940). Lift pinion adjusting shims out of housing (located behind rear bearing cup). To dismantle differential gears, remove locking screw, slide pinion shaft out, lift out gears, pinions, and thrust washers.

REASSEMBLY: Re-install and adjust parts as follows:

Pinion Bearing Assembly: Pinion bearing cups are press fit in housing. Rear pinion bearing cone is press fit on pinion shaft, front bearing cone is light press fit to close sliding fit on shaft. Replace bearings if rough when rotated with hand pressure. Use J-2934 Pinion Bearing Removing Plates and J-358-1 Holder in an arbor press to remove rear bearing cone and roller assembly, J-2935 Installing Plate and same holder to install new bearing (bearing must seat solidly against shoulder on shaft). Install correct pinion adjusting shim pack (see Pinion Setting data below) against shoulder of rear bearing bore in carrier, press rear bearing cup in place using J-2937 Rear Pinion Bearing Outer Race Installer and J-2940 Handle, then install front bearing cup using J-2939 Front Pinion Bearing Outer Rate Installer and J-2940 Handle. Place compressible spacer (and shim—see note below) or new type two-piece spacer (see Spacer Note below) on the pinion shaft, insert pinion in carrier, install front bearing cone and roller assembly (use arbor press if bearing is press fit). Install oil seal (oil the seal leather and outer diameter of seal with Permatex No. 3 or similar compound, tap seal in place using Bearing Installing Plate J-2935 to protect seal), install companion flange, oil the pinion shaft threads and face of the nut, turn nut on shaft loosely, then adjust bearing pre-load by tightening nut (below).

Pinion Bearing Preload Adjustment: Use J-2933 Companion Flange Holding Tool on flange, tighten nut on pinion shaft until bearing endplay is taken up (companion flange is felt to contact spacer) then tighten nut slowly (not more than 1/6 turns at a time), turning pinion shaft frequently to seat bearing rollers, and check bearing preload by measuring the pull required to turn the pinion shaft in inch-lbs., (use torque indicating wrench or spring scale, J-544-A attached to companion flange holding tool). Tighten nut only until correct bearing preload is secured as listed below After completing preload adjustment, secure the nut by staking end of pinion into nut recesses

Pinion Bearing Pre-load Setting
(1947-52 Models)

Pinion Bearings	Bearing Pre-load
New Bearings	27-37 in. lbs.
Old Bearings①	15-20 in lbs.

1953-55 Models

New Bearings	24-32 in. lbs.
Old Bearings①	15-20 in lbs.

①—After several thousand miles usage.

▷*CAUTION*—Do not exceed maximum preload specification when adjusting pinion. If this maximum figure exceeded by tightening nut excessively, disassemble axle and install new spacer.

▷Two-Piece Pinion Bearing Spacer Installation—1947-52 Models—Place compressible inner spacer (Part No. 510424, outer spacer (Part No 510425) and shims, if used, over pinion shaft Keeping pinion assembly in a vertical position, place assembly in carrier and slide front bearing over pinion shaft.

1953-55 Models—Place compressible inner spacer (Part No. 516760, outer spacer (Part No. 510425) and shim, if used over pinion shaft. If pinion shaft

CONTINUED ON NEXT PAGE

OLDSMOBILE HYPOID (C nt.)

is a sliding fit in front bearing, turn carrier in a horizontal position, then place pinion assembly into position in carrier and slide front bearing over pinion shaft.

All Models—If pinion shaft is a press fit in front bearing, use an arbor press to install the bearing. Use small end of a discarded compressible spacer as a tool to press bearing onto shaft while supporting pinion gear.

►**Pinion Bearing Spacer Shim Note**—A shim (.037" to .045" thick) is used between spacer and front bearing cone on some axles. This **shim must be reinstalled** if same spacer is re-used (discard shim if new spacer used). A new spacer must be used when: 1) New Ring Gear & Pinion set installed, 2) Any part of either pinion bearing is changed, 3) New Carrier casting installed, or 4) Pinion adjusting shim thickness increased.

Pinion Setting: Standard shim thickness for each carrier is indicated by mark on carrier flange as follows: D5—.015", D4—.014", D3—.013", D2—.012", D1—.011", 0 (Std.)—.010", S1—.009", S2—.008", S3—.007", S4—.006", S5—.005", (NOTE—"D" indicates carrier deeper, "S" that carrier shallower than standard). To this standard shim thickness (which is correct for all standard or unmarked pinions), add additional shims (when pinion marked +) or subtract shims (when pinion marked —) equal in amount to the figure following this + or — mark on end of the pinion (figures indicate shim thickness in thousandths). This total shim thickness will correctly position pinion for proper mesh with ring gear and shims should be installed in carrier ahead of rear pinion bearing cup. Shims are furnished in sizes listed below and should be used in combination for required thickness.

Shim Thickness	Part No.	Identification Color
.002"	509263	Plain
.003"	509264	①Blue
.004"	509265	②Copper
.005"	509266	Plain
.010"	509267	Plain

①—Or plain color with **one** punched hole.
②—Or plain color with **two** punched holes.

Differential Bearing Assembly: Bearing cones must be a heavy press fit on differential case hubs. Replace bearings if loose or if bearing feels rough when rotated by hand. Use T-278-R Differential Side Bearing Remover to remove old bearing roller and cone assemblies. J-941 Replacer to install new bearings. When reassembling axle, place ring gear and differential assembly in carrier so that backlash between ring gear and pinion is just taken up, place bearing adjusting nuts squarely against bearing cups, install bearing caps and tighten capscrews lightly (make certain that adjusting nut threads not crossed), then check differential bearing adjustment (below). If no new parts being installed, tighten bearing nuts to original position (as marked before disassembly).

Differential Bearing Adjustment: ***CAUTION—On "Piloted" type carriers, Pedestal Cap Clearance must also be checked and adjusted.***

Bearing Adjustment—With differential assembly installed in carrier, tighten bearing cap screws (CAUTION—no lockwashers used with these screws) so that adjusting nuts can just be turned, turn nuts in to original markings, or if not marked proceed as follows: Back off right hand nut 4 turns, tighten left hand nut until all backlash removed from ring and pinion gear, then back this left hand nut off 4 turns to position where slot in nut lines up with screw hole for lock. Tighten right hand adjusting nut slowly until bearing race just starts to turn with nut, tighten nut **additional 2-4 notches** for correct bearing pre-load and see that slot in nut lines up with screw hole for lock. Tighten all bearing cap screws to 70-75 ft.lbs. Check gear backlash with a dial indicator. If backlash is not .003-.006" (1947-52), .004-.006" (1953 & Later), adjust by backing off one of the adjusting nuts and tightening the opposite nut an exactly equal amount to avoid disturbing bearing pre-load. Check pedestal spread (see below) and if clearance not correct, adjust right hand adjusting nut one notch at a time (loosen or tighten as necessary), repeating check each time until correct clearance is secured. **Adjusting nut must not be tightened less than 2. or more than 4 notches.** On "Piloted" Carriers, check pedestal cap clearance as follows:

Pedestal Cap Clearance (All "Piloted" Carriers): After differential bearing adjustment completed and with bearing capscrews correctly tightened to 70-75 ft. lbs., install special ring gauge, Tool BT-23 (1949-52), J-5340 (Later), over pedestal caps so that it rests on machined surface at outer side of each cap, measure clearance between gauge and opposite cap with a feeler gauge. Clearance at this point must be .008" (1949-52), .004-.012" (Later). Correct this clearance by adjusting differential bearings (above).

►*NOTE*—If correct bearing clearance cannot be secured within range of bearing adjusting nut, loosen bearing capscrews and tap bearing caps lightly in or out with a hammer.

►*CAUTION*—Bearing caps must be loosened to allow adjusting nuts to be turned and must always be tightened to 70-75 ft. lbs. before checking clearance.

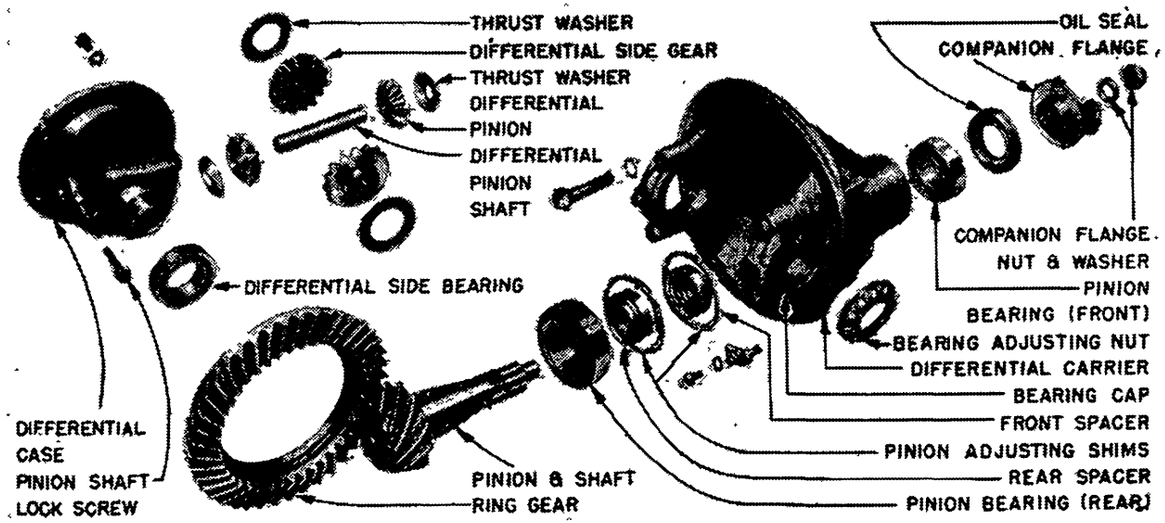
Piloted Carrier Installation in Axle Housing:

►***CAUTION—Piloted carriers must be installed as follows due to close fit between carrier pedestal caps and support plates in housing.***

1—Carefully clean mounting face of carrier and housing, install new gasket (No. 556042).

2—Install three pilot studs, Tool BT-24, in two bottom holes and one top hole of housing.

►***1953 NOTE—Pilot studs not necessary on this axle assembly. Pedestal bearing caps will seat down onto carrier pedestals with proper alignment of threads if adjusting nuts are properly seated, threads not crossed, or pedestal caps interchanged.***



3—Install carrier over pilot studs. Use four 7/16"—20x1½" capscrews (install two on each side of housing) to draw carrier into place in housing.

4—Remove pilot studs, install six regular 7/16"x1" carrier mounting capscrews, then remove temporary screws and install four regular capscrews in these holes.

5—Tighten all mounting screws evenly to 70-75 ft. lbs.

Ring & Pinion Gear Backlash Adjustment: Backlash should be .003-.006" (1947-52), .004-.006" (Later). Adjust by backing off one differential bearing adjusting nut and tightening opposite nut exactly and equal amount to avoid disturbing differential bearing adjustment. See Pinion Setting and Differential Bearing Adjustment Data

NOTE—Bearing adjusting nut locks can be bent slightly, if necessary, to engage slot in nut if nut not exactly aligned with lock after backlash and bearing adjustment correctly set.

OLDSMOBILE HYPOID AXLE (WITH TWO-PIECE PINION SPACER)

OLDSMOBILE REAR SUSPENSION (COIL SPRING TYPE)

Six & Eight, All Models (1946-50)
Eight, Series 88 (1951)

DESCRIPTION: Coil spring type with support arms (used with Hotchkiss Drive Rear Axle).

Spring & Support Arm Axle Mounting—Mounting consists of an insulator bracket on the axle housing, insulators installed in upper and lower faces of bracket, insulator cups on outer ends of insulators, and spacer extending through entire assembly. This assembly is clamped between spring mounting plate (top) and support arm (bottom) by two bolts. Lower end of coil spring is clamped on this top spring mounting plate by the rear bolt (bolt threads into lower spring clamp).

Coil Springs—Springs have small curled ends and may be installed with either end up unless one end coil has straight portion (this end must be installed at top). See Spring Installation.

Shock Absorbers—Shock absorbers now mounted on brake backing plates and linked to frame.

SUSPENSION UNIT REMOVAL & INSTALLATION:

Spring Removal: Disconnect hydraulic brake hose at axle, disconnect propeller shaft at rear universal joint and remove, disconnect shock absorber arms from links. Remove upper spring bolt and axle housing rear insulator bolt (this bolt threads into lower spring clamp and anchors lower end of spring). Raise car to remove weight from spring, remove spring and upper insulator washer. CAUTION—Although rear springs can be removed by raising rear end of car until flexible brake connection is just taut (without disconnecting brake line), this method not recommended.

Spring Installation:—Spring must be installed with curled end of small diameter end coil at bottom (if both ends curled, spring may be installed either end up—some springs may have straight end which must be installed at top). Install spring with curled end of coil to rear and 1/16" to right of center-line through support arm. With spring in position, install insulator washer on top of spring and spring clamps in upper and lower end coils (lower clamp has grommet nut, upper clamp does not have nut which is located in frame side rail). Turn clamps so that they grip end coils snugly (clamps are cam shaped—assembly will be facilitated if clamps taped to spring). Line up holes in clamp and frame, lower car slightly to hold spring in place, install upper clamp bolt, thread rear insulator bolt up through insulator assembly and in to lower spring clamp, tighten both clamp bolts securely. CAUTION—See that spring clamps are seated snugly in springs and that spring does not ride on raised portion of mounting plate.

Axle Housing Insulators & Bolts:—See 'Spring & Support Arm Axle Mounting' description above for insulator assembly details. Upper and lower insulator halves are different sizes (upper half is longer) and must not be interchanged. Insulators are marked by words 'upper' and 'lower' molded in the rubber. Front axle housing insulator bolt is 5⅜" long with right hand thread and should be installed with hexagon head at top. Rear bolt is 6" long with left hand thread and should be installed with hexagon head at bottom (bolt threads into lower spring clamp—no separate nut used).

CAUTION—Both insulator bolts should be tightened uniformly. Do not tighten bolts singly.

Support Arms:—To remove support arms, proceed as directed for spring removal above (do not disturb spring upper clamp bolt), removing both axle housing insulator bolts, push lower end of coil spring out of the way and remove insulators, plates, and cups. Free forward end of support arm from frame and remove arm. Install arm in same manner.

Track Bar:—Mounted on rubber bushings at each end. To remove bar, remove nut on stud at axle end, pry forward on arm to loosen serrated bolt, disconnect bar from frame cross-member bracket, rotate plate on frame end of track bar and remove bar.

REAR SPRINGS: May be identified by color mark (daub of paint) or Part Number stamped on outside of one end coil.

CAUTION—Part No. may be at top or bottom of spring and may not be visible with spring installed on car (remove spring to check number).

1946-48 Rear Spring Specifications

Car Model	Part No.	Color Mark
66, 68 Sdns. & Convt.	417920	Grey
66, 68 Club Sdn. & Convt.	417866	Yellow & Rust
66, 68 Sta. Wgn.	1310399	Red
76, 78 (All)	415472	Green & Yellow
98 Club Sedan	415472	Green & Yellow
98 (Others)	416401	Green & Grey

1949 Rear Spring Specifications

Car Model	Part Number	Color Mark

1946-52 PACKARD HYPOID

Six & Eight, All Models (1946-52)

▷CHANGES, CAUTIONS, CORRECTIONS

▷PINION BEARING PRE-LOAD CHANGE—30-35 in. lb. pinion bearing pre-load supersedes previous specifications. See Pinion Bearing Pre-load.

▷REAR AXLE OIL SEAL LEAKAGE CORRECTION: *When replacing axle shaft oil seals to correct complaints of oil or grease on rear brake linings, check the following points:*

▷Axle Housing Vent—*Must be kept open to prevent pressure building up in housing and forcing lubricant out.* Vent consists of drilled hole through screw attaching brake line tube junction on left side of axle housing.

▷Brake Support Plate Drain Holes—*Must be kept open to prevent oil or grease passing oil seal from being thrown on brake lining.*

▷Excessive Shaft Endplay—*Will cause seal wear and lubricant leakage.* Check and adjust endplay to .004-.007". When installing shaft, do not allow shaft to hang or drag on oil seal which may scuff seal or distort retainer.

▷Oil Seal Installation Cautions—Before installing new seal, check old seal for proper contact on shaft and leakage around outer rim, check shaft for roughness at seal bearing surface. If inner edge (lip) of seal has not been in contact with shaft due to extending too far into housing, shim out new seal by installing special spacer (can be made by cutting a single coil from a horn ring spring) in housing back of seal. To correct oil leakage around rim of seal, apply light film of gasket paste in housing bore before installing seal.
CAUTION—Apply gasket paste only at point where seal contacts housing and use sparingly.

▷PINION BEARING SPACER CAUTION (Some 2103, 2106, 2126 Cars): On these cars with rear axle carrier marked by two "8s" stamped in 1½" square pad on top of carrier, special 1/16" spacer used between pinion rear bearing cup and bearing cup shoulder in carrier. This spacer must always be used with these marked carriers.

▷*CAUTION—Rear axle will be noisy due to incorrect ring and pinion gear mesh if spacer omitted.*

DESCRIPTION: Hypoid gear, semi-floating type with Hotchkiss drive.

REMOVAL OF AXLE: *See "Rear Axle" on car model page.*

AXLE SHAFT REPLACEMENT & WHEEL BEARING ADJUSTMENT: See Oil Seal Leakage Correction above when replacing axle shafts. Use care not to damage oil seal.

Axle Shaft Replacement. To remove axle shaft, remove wheel, take off axle shaft nut and washer, remove hub and brake drum assembly (use puller), disconnect brake line, take out nuts in backing plate, remove seal guard, gasket, retainer, oil seal, backing plate, and bearing adjusting shims. Use puller J-2552 to remove axle shaft and bearing.

▷*CAUTION—Support weight of shaft while it is being withdrawn. Do not allow shaft to drag on inner oil seal (will damage or distort seal and cause oil leaks).*

Wheel Bearing Adjustment. Endplay up to .050" can be taken up by removing shims between backing plate and axle housing flange on one side. If endplay greater than .050", remove shims at both wheels equally for desired endplay of .004-.007".

CONTINUED ON NEXT PAGE

1946-52 PACKARD HYPOID (Continued)

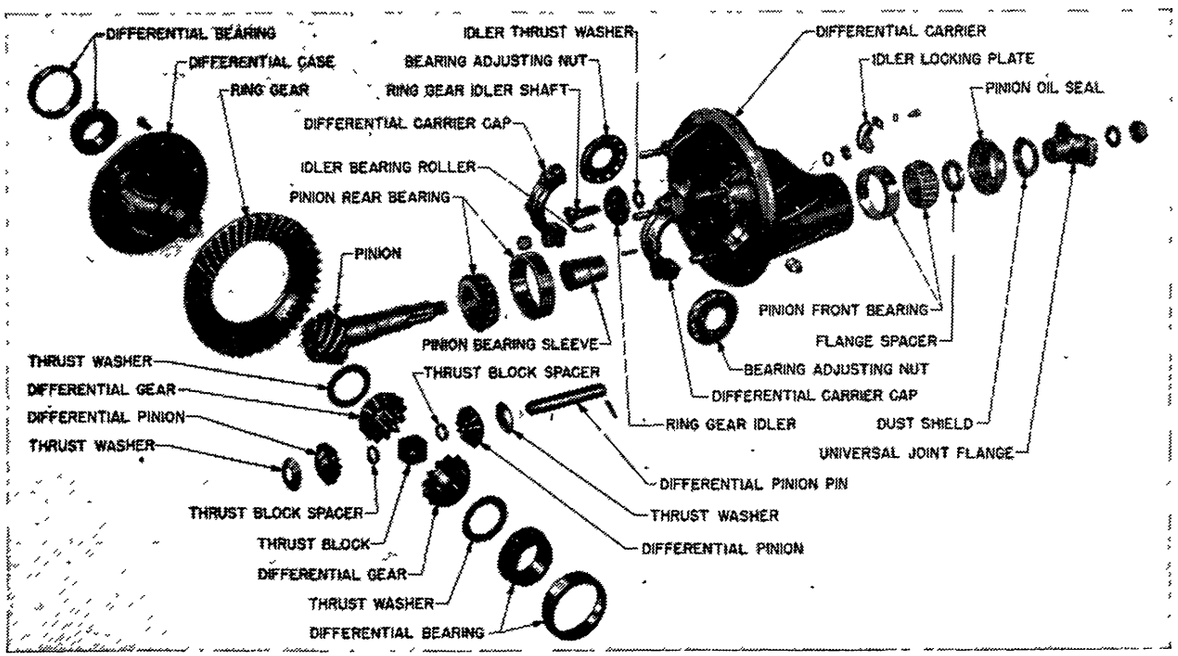
NOTE—These shims furnished in thicknesses of .005", .007", .020".

DISASSEMBLY & OVERHAUL: With carrier assembly removed from axle housing, mark both bearing caps, adjusting nuts and pedestals to insure correct reassembly. Remove adjusting nut locks, loosen bearing cap stud nuts, back off adjusting nuts, remove bearing caps, lift out differential assembly. Remove nut on end of pinion shaft, use puller J-2576 to remove universal joint flange from shaft. Use a soft hammer to drive pinion, rear bearing, and sleeve out through rear of carrier. Remove pinion shaft oil seal, lift out front bearing cone and roller assembly. Do not remove pinion bearing cups from carrier unless replacement is required (CAUTION—If rear bearing cup removed, see Pinion Bearing Spacer Caution above for spacer used on some axles). If pinion rear bearing being replaced, use Adapter Plate J-2574 to press bearing off in arbor press.

Pinion Bearing Assembly (1946 & Later): Press or tap pinion bearing cups in place in carrier bore (CAUTION—See Pinion Bearing Spacer Caution note above for spacer used on some axles). Press rear bearing cone and roller assembly on pinion shaft until tight against shoulder on shaft. Insert pinion in carrier, install spacer and front bearing cone and roller assembly on shaft. Install universal joint flange spacer (separate spacer used on some models only), lubricate new pinion bearing oil seal with engine oil, tap seal in place. Coat shaft splines with Lubriplate, install universal joint flange, dust shield, flange washer, and nut. Adjust bearings by tightening nut as follows:

Pinion Setting: Pinion position is not adjustable.

Pinion Bearing Pre-load: 30-35 in. lbs. turning torque to rotate pinion shaft only (ring gear out of carrier). Check pre-load and adjust bearings as follows:



CAUTION—This 30-35 in. lbs. pre-loud supersedes earlier specifications and it is recommended that pre-load be set at upper limit of 35 in. lbs. to compensate for any slight drop-off after car returned to service.

Pinion Bearing Pre-load Adjustment—With pinion completely assembled in carrier, but with ring gear out, tighten nut on end of pinion shaft finger tight. With torque wrench and adapter J-2571-B and socket J-2571-A check amount of torque required to rotate pinion. **This indicates the amount of drag caused by pinion shaft oil seal, and must be subtracted from final torque reading.** Tighten universal joint flange nut until corrected torque of 30-35 in. lbs. (final torque reading **minus** oil seal drag) is obtained.

Collapsible Pinion Bearing Sleeve—If new sleeve being used, collapse sleeve first by tightening nut until torque required to turn nut suddenly falls off. Then check pinion pre-load (see above).

Pinion Staking Note—Replace flat type nut with Hug-Lock (staking not required). If flat type must be used, stake in two places.

Differential Gear Assembly:—Differential side gear endplay should be .002-.005". Adjust by installing thrust washer of correct thickness between side gear and differential case. These washers furnished in various thicknesses as follows: .031" (No. 330797), .036" (324583), .041" (324584), .046" (324585). When assembling differential gears, make certain that thrust block and spacers (spacer on each side of block) installed on differential pinion pin between pinions. Lock the pinion pin in place by installing lockpin through hole in case and stake the edge of the hole to prevent pin working out in service.

1947-52 PACKARD HYPOID REAR AXLE

Differential Bearing Assembly: Use puller TR-278R to remove side bearings from case. Bearing cones should be .001-.002" tight (if new bearing loose, replace case). Adjust bearings after assembly installed in carrier as follows:

Differential Bearing Adjustment—Bearings should be pre-loaded so that "spread" of bearing support pedestals of .010-.012" is secured. To make this adjustment, free adjusting nut locks. Loosen bearing cap nuts slightly to free adjusting nuts, make certain that there is some backlash between ring gear and pinion and clearance between ring gear and support roller (when used). Then back off right hand bearing adjusting nut until ring gear and differential assembly is loose in its bearings. Use accurate caliper and set caliper so that it will just slide over differential carrier with one leg resting on machined boss (adjusting nut lock pin boss) on each side of carrier **with .010" feeler between boss and caliper on one side.** Remove feeler, tighten right hand adjusting nut until caliper will just slide in place with the feeler removed (pedestals will have 'spread' this .010"). Correct pedestal spread should be .010-.012". After bearings adjusted and ring gear backlash checked (below), tighten bearing cap stud nuts to 65-70 ft. lbs. or bearing cap screws to 55-60 ft. lbs. and install adjusting nut locks. Adjust ring gear support roller clearance.

Ring Gear Support Roller Adjustment (Some Models only)—After adjusting ring gear backlash and differential bearing pre-load, adjust ring gear support roller by loosening lockscrew on roller stud sector plate and turning roller stud so that clearance between roller and back face of ring gear is .005". Make certain that sector plate and lockscrew are tight after making adjustment.

►***CAUTION—Rotate ring gear and make certain that mounting screw lock wires do not interfere with support roller.***

Ring Gear Backlash Adjustment: Backlash should be .004-.006". Adjust by backing off one bearing adjusting nut and tightening opposite nut exactly same number of notches to avoid disturbing bearing adjustment. NOTE—Backing off one nut and tightening opposite nut **one notch each** will change backlash approximately .004".

Ring Gear Replacement: When installing new gear, see that back face of gear and mounting face on differential case are clean and free from burrs. Check ring gear flange and pilot run-out on case which must not exceed .001". Install ring gear mounting screws, tighten screws evenly to 50-55 ft. lbs. (3/8"-24 screws), 70-80 ft. lbs. (7/16"-20 screws). Secure the mounting screws in pairs with lock wire through screw heads (CAUTION—see that lock wire does not interfere with support roller). Check ring gear for run-out after assembly mounted in carrier. Run-out at back face of ring gear must not exceed .004".

Lateral Stabilizer Installation (Clipper Models). The stabilizer must be installed in such a position that the air dome on the shock absorber (at one end of the stabilizer) is upward. Shock absorber rod guide and seal assembly (at piston rod end of shock absorber cylinder) must be turned so that wrench slots are at 45° to the air dome so air vent groove in guide will be at uppermost point in cylinder.

1953-55 PACKARD HYPOID

All Models (1953-55)

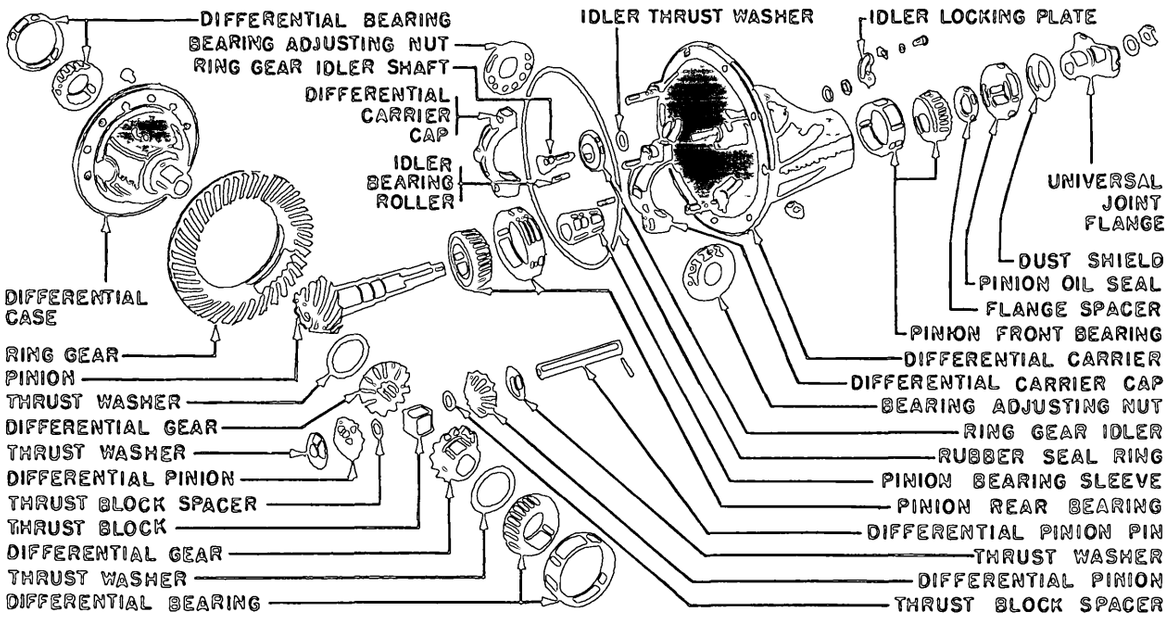
▷*REAR AXLE ASSEMBLY NOTE: Axle similar in design to previous types, but with heavier construction. Housing is heavier, bearings are larger, and axle shafts are larger.*

▷*PINION BEARING PRE-LOAD CAUTION: Adjustment procedure and settings changed. See OVERHAUL data below.*

DESCRIPTION: Hypoid gear, semi-floating type with Hotchkiss drive.

REMOVAL OF AXLE: *See "Rear Axle" on Car Model page.*

AXLE SHAFT REPLACEMENT & ENDPLAY ADJUSTMENT: Raise car and place stand under each side of frame near rear spring front hanger. Remove rear wheel from hub and drum, then raise rear axle housing and place stands under housing near outer end. Remove hub and drum assembly using puller J-4153 (*CAUTION—Do not use "knock-off" type puller*). Disconnect hydraulic brake line from wheel cylinder. Remove brake support attaching nuts and lock washers. Remove seal guard, gasket, retainer, oil seal, brake support, and axle shaft bearing adjusting shims. Remove axle shaft and bearing using puller J-2552. *CAUTION*—Be careful that the axle shaft splines do not damage inner seal. To install axle, reverse the removal procedure. Adjust endplay by installing Tool J-2560, then with axle shaft forced in toward differential, turn long adjusting screw to bear aaginst backing plate, and then pull shaft outward. Check with feeler gauge to determine clearance which should be .004-.007". Add or remove shims at backing plate to obtain specified clearance.



OVERHAUL: Carrier can be removed from rear axle housing without removing axle assembly from car.

Carrier Removal: Remove axle shafts (see above), and disconnect propeller shaft at rear universal joint by removing screws and lock plates (On Ultramatic Drive cars, the universal joint is disconnected by removing bearings and cross from yoke). Prop propeller shaft up against floor with block of wood under it at "X" member. Drain lubricant from housing, and clean area around carrier gasket, then remove carrier and gasket from axle housing.

Carrier Disassembly: Securely clamp carrier flange in a soft jawed vise. Measure differential case run-out and replace if run-out exceeds .004". Mark carrier side bearing caps, bearing adjusting nuts, and pedestals with punch marks to insure correct installation. Remove carrier bearing capscrews. Hold ring gear and differential case in place with one hand and lightly tap bearing caps loose with hammer. Lift off differential case bearings, bearing cups, adjusting nuts and caps. (CAUTION—Bearing cap, bearing cup, and adjusting nut should be kept together until reassembly.)

Differential Disassembly: Remove ring gear attaching cap screws, tap the outside of ring gear with a soft hammer and loosen it. Remove ring gear from case. Drive out the differential pinion shaft lock pin, using a pin punch and hammer. Drive out pinion shaft. Remove differential pinions, pinion thrust washers, axle shaft thrust block, and spacers, differential side gears and thrust washers. Differential side bearings may be removed if necessary, using Tool J-3250, and adapter plate J-3250-4.

Pinion Shaft Removal: Remove universal joint flange nut using socket wrench J-5512, while holding flange from turning with Tool J-2659. Drive universal joint flange from shaft using a soft hammer. Drive out pinion, sleeve, and rear bearing using a soft hammer, then drive out pinion oil seal and front bearing in the same manner. Drive out front bearing cups from housing using Tool J-872-5, and Tools J-3235-A (front bearing cup), or J-5521 (rear bearing cup). Remove pinion rear bearing using Plate Holder J-2574 and Remover P-5508 in arbor press.

PACKARD HYPOID REAR AXLE

Pinion Shaft Installation: Install pinion bearing cups using Tool J-872-5 and Tools J-3230-A (rear cup), J-5506 (front cup). Press the pinion rear bearing onto pinion shaft until inner race is tight against shoulder. Install the pinion shaft collapsible spacer on shaft with large diameter of spacer toward rear bearing, then install assembly in carrier. Lubricate and install front bearing and tap into place on shaft. Lubricate pinion oil seal and install it in carrier using Tool J-3244. Coat splines of shaft with oil and install universal joint flange or yoke, dust shield, washer, and a new nut.

Pinion Bearing Preload Adjustment: (With carrier assembly out of car and with differential assembly removed)—Lock universal joint flange in vise and tighten flange nut with socket wrench J-5512 and a long handle wrench until only a slight amount of endplay can be felt in pinion shaft. *(NOTE—If a new collapsible sleeve is being used, a great amount of turning effort on the wrench will be required to buckle the sleeve).* Using a preload indicator wrench and adapter Tool J-2571-B and socket J-5512, notice the amount of torque required to rotate the pinion. This indicates the amount of drag caused by pinion seal. After seal drag torque is obtained, continue tightening the flange nut until pinion bearing preload is correct, the torque reading on the preload indicating wrench will read 2½ to 3 ft. lbs. PLUS the amount of torque that was required to overcome the oil seal drag (above). *(For example, if the oil seal drag was 2 ft. lbs., the reading on the indicating wrench should be 4½ to 5 ft. lbs.).*

Pinion Bearing Preload Adjustment: (With carrier and axle assembly in car)—Raise rear of car so that wheels are off floor. Be sure rear brakes are not dragging (it may be necessary to loosen rear wheel brake adjustments). Disconnect rear universal joint from pinion flange. Loosen the pinion flange nut (with Tool J-5512) and tap pinion shaft lightly to insure removing all preload on bearings. With preload indicating wrench and socket (J-5512), measure the amount of torque required to turn pinion shaft, differential, and rear wheels (rotate pinion shaft a few turns before taking torque reading). While holding universal joint flange with a large wrench, or applying the brakes, tighten pinion shaft nut until preload of 15 ft. lbs. is obtained, PLUS the amount of torque required to overcome drag of rear wheels, differential and pinion shaft (above). While pinion bearings are under the 15 ft. lbs. preload, strike the differential carrier a couple of sharp blows directly over front and rear bearing cups with a brass hammer. *(CAUTION*—Do not operate car at this high pinion bearing preload). Loosen pinion shaft nut until pinion shaft turns free, then retighten nut to obtain 2½ to 3 ft. lbs. torque on pinion bearings PLUS the amount required to overcome drag of rear wheels, differential and pinion shaft (above). Connect rear universal joint to pinion flange, and adjust the rear brakes.

Differential Reassembly: Install differential side bearings using Tool J-5507 and Handle J-872-5. Install differential side gear thrust washers on hubs of

CONTINUED ON NEXT PAGE

1953-55 PACKARD HYPOID (Continued)

side gears, sticking them in place with cup grease. Install differential side gears and thrust washers in case. Coat cupped side of differential pinion thrust washers with grease and stick them to outer end of pinions, then place pinions in mesh with side gears, opposite each other, and rotate the side gears with the pinions until bore in pinions line up with pin bore in differential case. Start pinion pin into differential case so lockpin hole will line up with lockpin hole in case. As the pinion pin is pushed into case, install the thrust washer. Push pinion pin all the way in until lockpin hole registers with hole in case. (CAUTION—Measure the endplay of each side gear with feeler gauge placed between gear and thrust washer. If endplay not within .0015-.003" replace thrust washers with washers of correct thickness which are furnished in the following sizes: .031", .036", .041" & .046"). When correct endplay is obtained, and pinion pin installed, drive in the lockpin and stake edge of lockpin hole in case. Install ring gear on differential case and tighten capscrews evenly to 50-55 ft. lbs. Lubricate differential side bearings and place cups on bearings. Install differential assembly in carrier and install side bearing adjusting nuts and turn it in to make sure it is threading properly. Install bearing caps, lining them up with marks made at disassembly. Tighten capscrews enough to hold adjusting nuts in place and allow them to be turned. Temporarily adjust ring gear to pinion lash to approx. .010".

Differential Bearing Preload & Backlash Adjustment: Bearing preload is determined by measuring spread of carriers with a large outside caliper and a .010" feeler gauge. Back off side bearing adjusting nut on ring gear side one full turn so a little endplay can be felt in differential case. Place caliper and .010" feeler gauge against boss on pedestal cap and adjust caliper so jaw contacts pedestal boss on other side of differential case, to determine distance from outside of one pedestal to outside of other pedestal. Lock jaws of caliper in place so they will not be disturbed. Tighten the side bearing adjusting nut on ring gear side one full turn (previously backed off). Tighten adjusting nut opposite from ring gear side until caliper jaws will just contact both pedestal cap bosses **without** feeler gauge. (CAUTION—recheck pedestal spread).

Backlash Adjustment—Mount a dial indicator on carrier flange with indicator contact resting on face of ring gear tooth. Backlash should be .004-.008". By turning BOTH side bearing adjusting nuts in the same direction, ring gear can be moved toward or away from ring gear without disturbing side bearing preload. (NOTE—Moving both side bearing adjusting nuts in the same direction ONE NOTCH changes backlash .004"). Tighten side bearing cap bolts, recheck backlash.

Carrier Installation: Install new carrier sealing ring holding it in place with heavy grease. Install plastic seals on carrier studs and install carrier in axle housing. Tighten all carrier nuts to 35-40 ft. lbs.

Pedestal Set Screw Adjustment—(PRODUCTION CHANGE NOTE—Two set screws on early type; one set screw on ring gear side, later type). Tighten set screws in rear of axle housing to 2 ft. lbs. (Early type—two set screws). 2 to 3 ft. lbs. (Later type—one set screw). Hold screw with Allen wrench and tighten locknut.

PONTIAC HYPOID

Six & Eight, All Models (1947-55)

►CHANGES, CAUTIONS, CORRECTIONS

►**PINION BEARING PRE-LOAD CAUTION: Pinion bearing pre-load must be adjusted** whenever universal joint companion flange nut on pinion shaft loosened (pre-load controlled by this nut and will be disturbed whenever nut loosened for any reason). See Pinion Bearing Pre-load data.

►**1952 & LATER DIFFERENTIAL CASE ASSEMBLY CAUTION (3.08-1 RATIO)**—New and larger differential case and carrier assembly required with this ratio. NOT INTERCHANGEABLE WITH OTHER RATIOS.

►**1952 REAR AXLE SHAFT TEMPORARY PRODUCTION CHANGE**—A modified axle shaft having an oil reservoir built into the outer bearing retainer (does not have axle housing oil deflector or brake drum oil deflector) was used for a short period during production. This axle can be identified by the spring nuts on two opposite wheel studs. If axle shaft is to be replaced, the regular service axle shaft and components should be used.

►**1952 RING GEAR BOLT PRODUCTION CHANGE**—Bolts now being used in production do not require lock washers. Machined area around bolt holes has been increased for use of a socket wrench. New style bolts should be tightened to 55-60 ft. lbs. torque. When using old style bolts for replacement, lock washers must be used, and bolts tightened to 35-40 ft. lbs. torque.

►**REPLACEMENT AXLE SHAFT CAUTION**—Axle shafts are covered with a protective coating of rust inhibiting grease. This grease must be completely removed before shaft installed in car (particularly between axle flange and oil guard flange) to prevent grease melting and running out on brakes.

►*1955 SPACER PRODUCTION CHANGE:* Early production differential have a two-piece spacer which fits over pinion stem and bears against inner races of pinion bearings. Late production differentials have a one-piece spacer which fits over pinion stem and bears against a shoulder on drive pinion and inner race of front bearing. **New spacer is not serviced. Ue new two-piece spacer for replacement of one-piece or two-piece spacer.**

AXLE IDENTIFICATION: Color identification markings are found on end of axle shaft and code number is stamped on pad on differential carrier.

Ratio	Code Number	Color
3.08-1 (40-13)	0	Yellow
5.55-1 (41-9)	1	
4.3-1 (43-10)	2	White
4.1-1 (41-10)	3	Green
3.90-1 (39-10)	4	Red
3.64-1 (40-11)	6	Blue
3.42-1 (41-12)	8	Aluminum
3.23-1 (42 13). . . .	9	Brown

DESCRIPTION: New hypoid gear, semi-floating type. Design similar to axle used on previous models except for new pinion bearing assembly and other points listed below.

Differential Side Gears & Pinions—Gears are new type with "crowned" teeth to insure tooth bearing at center. Gears and pinions are interchangeable with previous type in complete sets only (individual gears and pinions must not be interchanged).

REMOVAL OF AXLE: *See "Rear Axle" on car model page.*

AXLE SHAFT REPLACEMENT: Wheel bearings not adjustable (ball bearings). Replace shafts as follows:

Axle Shaft Replacement. Wheel mounting flange integral with axle shaft. Bearings are special shielded type (lubricated at factory) pressed on axle shaft and held by retainer collar pressed on shaft. To remove shaft, remove wheel and brake drum, remove nuts from four bolts holding backing plate on housing, withdraw axle shaft (use puller J-942) taking care not to drag shaft on oil seal or to dislodge backing plate which will damage brake line. New bearings must be installed whenever removed from shaft. To remove bearings, use chisel to split retainer, press bearing off using special tool J-947 on outer race (pressure exerted on outer race which may burst if tool not used). Use same tool to install new bearing (pressure on inner race only) and retainer, pressing bearing on shaft against shoulder. Install shaft with left hand wheel studs on left hand side of car, shaft with right hand studs on right side of car. To renew oil seal, use tool J-943 to remove seal assembly, lubricate new seal with oil and coat outside rim of retainer with Permatex, use J-5818 to install seal assembly. *NOTE*—Adapter is furnished with tool for use in installing seals on 1954 and earlier rear axle shaft oil seals.

►***CAUTION—Use care not to dislodge backing plate which will damage brake line, or to drag shaft on oil seal which will damage or distort seal.***

►**IMPORTANT SERVICE CAUTION:** Pinion bearing pre-load is controlled by universal joint companion flange nut on pinion shaft and bearing adjustment will be disturbed when this nut is loosened. **Pinion bearings must be adjusted each time companion flange nut is disturbed.**

DISASSEMBLY: With rear axle removed from car, remove axle shaft, take out mounting screws and remove carrier assembly. Disassemble carrier assembly as follows: Mark differential bearing caps and adjusting nuts to insure reassembling parts in same relative positions and to same settings. Remove the differential bearing caps and adjuster nuts, lift differential case and ring gear assembly out. Remove universal joint companion flange nut (use holding tool J-2933 and 1" socket wrench), pull companion flange (tool J962) taking care that pinion does not fall out. Remove pinion through rear of carrier using care not to damage pinion shaft threads or oil seal (if pinion does not slide out, tap pinion out with a soft hammer, or press pinion out in an arbor press), lift compressible spacer and shim from pinion shaft (NOTE—On some cars, a shim .037-.045" thick may be found between spacer and front bearing cone, this **shim must be re-installed** if same spacer used when axle reassembled). Remove oil seal, lift front bearing cone and roller assembly out. Press front and rear bearing cups out of housing in an arbor press (use Front Pinion Bearing Race Remover J-2938 & Removable Handle J-2940; Rear Pinion Bearing Race Remover J-2936 & Removable Handle J-2940). Lift pinion adjusting shims out of housing

CONTINUED ON NEXT PAGE

PONTIAC HYPOID (Cont.)

(located behind rear bearing cup). To dismantle differential gears, remove locking screw, slide pinion shaft out, lift out gears, pinions, and thrust washers.

REASSEMBLY: Re-install and adjust parts as follows:

Pinion Bearing Assembly: Pinion bearing cups are press fit in housing. Rear pinion bearing cone is press fit on pinion shaft, front bearing cone is light press fit to close sliding fit on shaft. Replace bearings if rough when rotated with hand pressure. Use J-2934 Pinion Bearing Removing Plates and J-358-1 Holder in an arbor press to remove rear bearing cone and roller assembly. J-2935 Installing Plate and same holder to install new bearing (bearing must seat solidly against shoulder on shaft). Install correct pinion adjusting shim pack (see Pinion Setting data below) against shoulder of rear bearing bore in carrier, press rear bearing cup in place using J-2937 Rear Pinion Bearing Outer Race Installer and J-2940 Handle, then install front bearing cup using J-2939 Front Pinion Bearing Outer Race Installer and J-2940 Handle. Place compressible spacer (and shim—see note below) or new type two-piece spacer (see Spacer Note below) on the pinion shaft, insert pinion in carrier, install front bearing cone and roller assembly (use arbor press if press fit). Install oil seal, first oiling seal leather and coating outer diameter of seal with Permatex 3 or similar compound, tap seal in place using Bearing Installing Plate J-2935 to protect seal, install companion flange, oil the pinion shaft threads and face of the nut, turn nut on shaft loosely, then adjust bearing pre-load by tightening nut (below).

▷Two-Piece Pinion Bearing Spacer Installation—Place compressible inner spacer (Part No. 510424), outer spacer (Part No. 510425), and shims (if used) over pinion shaft. If pinion shaft is sliding fit in front bearing, turn carrier in a horizontal position, then place pinion assembly into position in carrier and slide front bearing over pinion shaft. If pinion shaft is a press fit in front bearing, use an arbor press to install bearing. Use small end of a discarded compressible spacer as a tool to press bearing onto pinion shaft while supporting pinion gear.

▷Pinion Bearing Spacer Shim Note—A shim (.037" to .045" thick) is used between spacer and front bearing cone on some axles. This shim must be re-installed if the same spacer is re-used (discard shim if new spacer is used). A new spacer must be used when: 1) New Ring Gear & Pinion set installed, 2) Any part of either pinion bearing is changed, 3) New Carrier casting installed, 4) Pinion adjusting shim thickness increased.

Pinion Bearing Pre-load Adjustment: Use J-2933 Companion Flange Holding Tool on flange, tighten nut on pinion shaft until bearing endplay is taken up (companion flange is felt to contact spacer), then tighten nut slowly, turning pinion shaft frequently to seat bearing rollers, and check bearing pre-load by measuring the pull required to turn the pinion shaft in inch-pounds (use torque indicating wrench or spring scale attached to companion flange holding tool). Tighten nut only until correct bearing pre-load is secured as listed below. After completing pre-load adjustment, secure the nut by staking end of pinion shaft into nut recesses.

Pinion Bearing Pre-load Setting

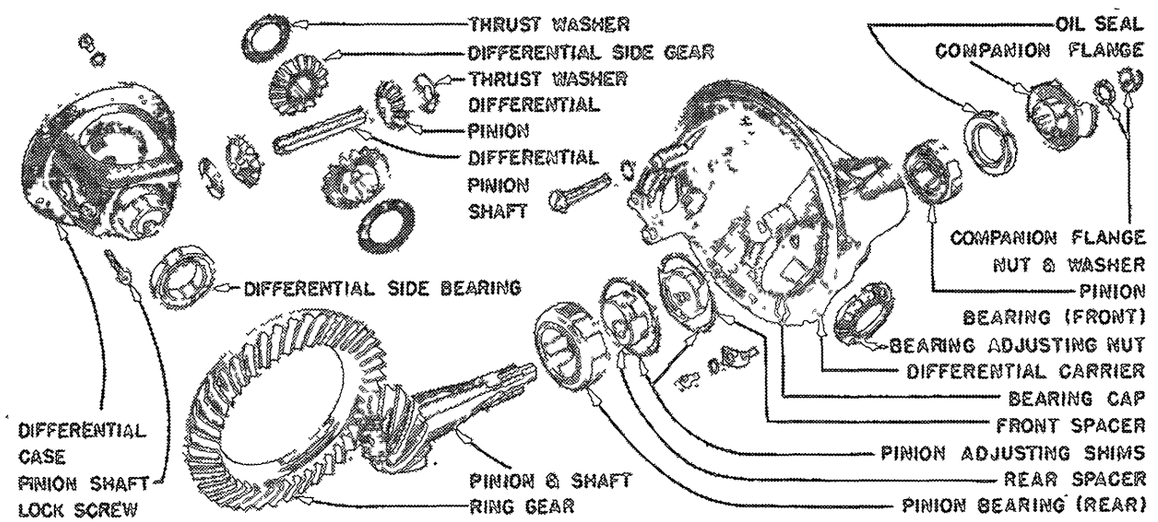
Pinion Bearings	Bearing Pre-load
New Bearings	27-37 in. lbs.
Old Bearings①	②10-12 in. lbs.

①—After several thousand miles usage.
②—Supersedes original specification of 15-20 in. lbs.

▷*CAUTION*—When adjusting bearing pre-load, do not exceed maximum (37 inch-pound) specification. If this figure exceeded by tightening nut excessively, disassemble axle and install new spacer.

Pinion Setting: Standard shim thickness for each carrier is indicated by mark on carrier flange as follows: D5—.015", D4—.014", D3—.013", D2—.012", D1—.011", 0 (Std.)—.010", S1—.009", S2—.008", S3—.007", S4—.006", S5—.005" (NOTE—"D" indicates carrier deeper, "S" that carrier shallower than standard). To this standard shim thickness (which is correct for all standard or unmarked pinions), add additional shims (when pinion marked +) or subtract shims (when pinion marked —) equal in amount to the figure following this + or — mark on end of the pinion (figures indicate shim thickness in thousandths). This total shim thickness will correctly position pinion for proper mesh with ring gear and shims should be installed in carrier ahead of rear pinion bearing cup. Shims are furnished in sizes listed below and should be used in combination for required thickness.

Shim Thickness	Part No.	Identification Color
.002"	509263	Plain
.003"	509264	①Blue
.004"	509265	②Copper
.005"	509266	Plain
.010"	509267	Plain



①—Or plain color with one punched hole.
②—Or plain color with two punched holes.

Differential Bearing Assembly: Bearing cones must be a heavy press fit on differential case hubs. Replace bearings if loose or if bearing feels rough when rotated by hand. Use TR-278-R Differential Side Bearing Remover to remove old bearing roller and cone assemblies, J-941 Replacer to install new bearings. When reassembling axle, place ring gear and differential assembly in carrier so that backlash between ring gear and pinion is just taken up, place bearing adjusting nuts squarely against bearing cups, install bearing caps and tighten capscrews lightly (make certain that adjusting nut threads not crossed), then check differential bearing adjustment (below). If no new parts being installed, tighten bearing nuts to original position (as marked before disassembly).

Differential Bearing Adjustment: With adjusting nut locks removed and bearing capscrews loose enough so that bearing adjusting nuts can be turned, mark position of both adjusting nuts, back off right hand nut slowly to point where right bearing cup stops turning with the nut, mark this new position (amount the nut turned between these two points is "notches tight" of original setting and should be 2½ minimum, 4 maximum). If bearing cup did not turn with the nut when the nut was loosened, or if "notches tight" of original setting incorrect, adjust bearings by turning right hand adjusting nut up until bearing cup just begins to turn with nut, then tighten nut not less than 2½ notches, or more than 4 notches, additional. Check ring gear backlash (see note below), tighten bearing capscrews securely, install adjusting nut locks.

Ring & Pinion Gear Backlash: .003-.012". Adjust by backing off one differential bearing adjusting nut and tightening opposite nut exactly equal amount (to avoid disturbing differential bearing adjustment). See Pinion Setting and Differential Bearing Adjustment data.

▷Ring Gear Backlash Adjustment Note—When adjusting differential bearings (above), if ring gear has slight backlash (.005"), equalize differential bearing adjustment by tightening each adjusting nut 1½-2 notches (do not make entire adjustment at right hand nut). Backlash can be adjusted without disturbing differential bearing adjustment by backing off one bearing adjusting nut and tightening opposite nut exactly same number of notches.

PONTIAC HYPOID REAR AXLE (WITH TWO-PIECE SPACER)

1946-53 BUICK

ALL SERIES (1946-53)

►*1952 SERIES 40, 50 (LATE) CASTER PRODUCTION CHANGE:* Beginning with Oct. 20, 1952 production, all Series 40 & 50 cars have the new "zero" caster knuckle (Caster setting changed to 0°; Limits Pos. ¾° to Neg. ½°) *CAUTION—Zero caster cannot be readily achieved on Early 1952 Series 40 & 50 prior to the above production change as these models do not have the required adjustment range. IT IS ADVISABLE TO SET CASTER AS LOW AS POSSIBLE ON THESE MODELS.*

►*1953 LOWER CONTROL ARM AND SHAFT ASSEMBLY PRODUCTION CHANGE:* Lower control arm and shaft assembly (Buick Part No. 1391188) replaces the right and left lower control arms previously used. The new arm will have the two outer rivets omitted, and bolts, washers and nuts will be included for installation of bumper retainer with the stabilizer connection on either side.

►CHANGES & CORRECTIONS

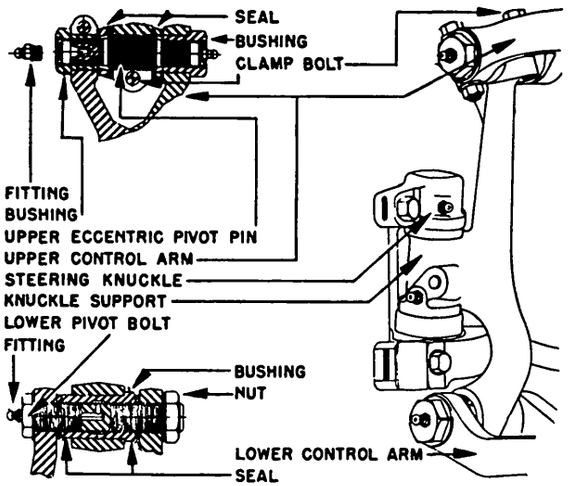
►**1949 Type Upper Pivot Pin & Bushing Installation on 1939-48 Series 40, 50, 70 Cars**—New type pivot pin with greater eccentricity, providing 50% greater range of Camber adjustment, can be installed on these earlier cars as complete set with bushings.

►***CAUTION—1949 Pivot Pin and Bushings must be used together (do not install separately).***

DESCRIPTION: Independent, linked parallelogram type with coil springs. Shock absorber is part of upper control arm assembly.

CHECKING & ADJUSTMENT: Before checking front end, check and adjust front wheel bearings, wheel run-out, tire inflation, and front end trim dimension, and see that car is at curb weight.

Tire Inflation—Inflate tires evenly as follows:
1946-47—25 lbs. (Cold), 28 lbs. (Warm) all tires.
1948-49—(Series 40 & 79 Estate Wagon) 25 lbs. Cold, 29 lbs. Warm (Series 50), 24 lbs. Cold, 27 lbs. Warm. (Series 70 exc. 79) 22 lbs. Cold, 25 lbs. Warm.
1950-53—(All Series) 24 lbs. Cold (after standing for 3 hours or driven less than 1 mile), 26 lbs. (after car driven more than 3 miles at less than 40 MPH), 28 lbs. (after car driven 3 miles at more than 40 MPH).



Kingpin Inclination—4¼° with camber of ⅜°.

Trim (Front Spring) Dimension: Bounce front end of car up and down several times to check for binding in suspension system, allow springs to assume natural position. With car at curb weight, measure from lower edge of frame cross-member (at bumper bracket) vertically to top edge of lower control arm. Trim dimension should be within limits shown below and lower control arm heights should be same on both sides of car. NOTE—1950 & Later cars have ¼" higher front springs for increased road clearance and Opt'l high springs have been discontinued as a factory option (these springs available for service installation in field).

►**Trim Dimension Correction**—If trim dimension not within limits, install special shims on low springs or replace springs. See Spring data.

①1948-53 Front Trim Dimensions

1948 All Series	3¾"
1949 50 (Exc. 56C)	4"
1949 70 (Exc. 76C)	4"
1949 56C & 76C	3¾"
1950-51 56C, 56R③	②3¾"

BUICK FRONT SUSPENSION

1948-53 Front Trim Dimensions (Cont.)

1950-51 75R, 76C, 76R③	②3¾"
1950-51 (All Others)③	②4"
1952 (Exc. 46C, 56C, 76C③	②4"
1952 46C, 56C, 76C③	②3¾"
1953 40 & 50 (Exc. 46C, 56C)④	②4"
1953 46C & 56C④	②3¾"
1953 70 (Exc. 76C, 76X)④	②3¾"
1953 76C④	②3⅜"
1953 76X④	②3½"

①—All specifications are plus or minus ¼".
②—Optl. High Springs not used on 1950 cars.
③—New cars will be 3/16" higher.
④—New cars will be ¼" higher.

Caster: *CAUTION—See 1952 Caster Production Change above.* Caster on both sides of car must be equal within ½°.

Caster	Desired	Limits
1946-47	Pos. ⅜°	0° to Pos. 1⅛°
1948-1952 (Early)	Pos. ¾°	Pos. ¼° to Pos. 1½°
1952 (Late)—1953	0°	Pos. ¾° to Neg. ½°

Adjustment—Remove lubricant fitting from bushing at outer end of upper suspension arm, (front bushing on right side, rear bushing on left side of car), loosen clamp bolt in upper end of knuckle support, insert Allen wrench through lubricant fitting hole, turn pivot pin to adjust caster (CAUTION—Camber will be changed unless pin rotated in complete turns only, check camber after adjusting caster), and toe-in if caster changed more than ¼°.

Camber: Positive ⅜° desired (Limits ⅞° Pos. to ⅝° Neg.) and equal within ¾° on both sides of car.

To Adjust—Same as for Caster adjustment (see above). Entire range of camber adjustment is obtainable within ½ turn of eccentric pin in either direction. CAUTION—Turning eccentric pin changes both Caster and Camber settings. Adjust both caster and camber together and "average" settings (both settings as near desired setting as possible and within limits).

Toe In: 1/16-⅛" (measure between marked points on tires at front of wheel, then roll car ahead ½ revolution and measure between same points at rear. **Adjustment**—Loosen clamp bolt at outer end of each tie rod, turn adjusting sleeve in outer end of each tie rod equally (⅜ turn of adjusting sleeve on each sid changes toe-in ⅛").

►*CAUTION*—When tightening clamp bolts, see that clamps are within ⅛" of rod ends and that ear of clamp overlaps slot in tube by not less than 1/16".

Steering Geometry: With outer wheel turned 20°, inner wheel should be turned 21½° plus or minus ¾°.

SPRINGS: Optl. High Spr'g Note. These springs higher, can be installed to correct excessive bottoming.

►*1950 & LATER SPRING CHANGES*—Springs have same part number as former springs but are ¼" higher (front), ¾" higher (rear) for increased road clearance and to prevent bottoming. Opt'l. high springs are continued for service replacement only.

76X (Dynaflow)	1335808
76X (Export—High Springs)	1163279
72R, 76R (Dynaflow)②	1340981

①—Without Air-Conditioning.
②—With Air-Conditioning.

Spring Height Correction—If spring too low (trim dimension not within limits), special shims (⅛" thick) may be installed on upper end of spring.

►*CAUTION*—If more than three shims required to correct spring height, replace spring.

►**Rear Spring Note**—*See "Buick Rear Suspension" in Rear Axle Section for Std. and special Rear Springs.*

C NTINUED ON NEXT PAGE

1946-53 BUICK (Cont.)

FRONT SPRING REPLACEMENT: (Removal)—Place jack under lower control arm, raise wheel off floor and remove wheel and tire. Disconnect stabilizer link from lower control arm and disconnect outer end of tie rod from steering arm. Remove lower pivot pin nut, pivot pin, washer and dirt seals. Support car frame by another jack and slowly lower the jack under the lower control arm. This will allow lower control arm to drop low enough to remove chassis spring.

Installation—Before installation of front spring, check the part number which is stamped on one end coil to make sure that spring is correct (See Front Spring Table above), for car model. Make sure that rubberized fabric insulation is in place around the spring center cup on frame, and is in good condition. Place small end coil of spring over the center cup and as lower control arm is raised, position lower end of spring so that end coil seats in the recess provided in spring seat. Support lower control arm on jack. Slip the lower pivot pin dirt seals over outer ends of lower control arm. Centralize lower end of knuckle support between outer ends of lower control arm, then install lower pivot pin and lockwasher from front side and tighten securely. Install and tighten nut. Snap dirt seals into place over pivot pin. Connect tie rod outer end to steering arm, and connect stabilizer link to lower control arm. Adjust stabilizer link grommets by tightening grommet retainer nuts to secure a measurement of 1 11/16" between top of upper grommet retainer and bottom of lower grommet retainer. Make this adjustment on each end of link. Install wheel and tire assembly, then check front end alignment.

SHOCK ABSORBERS: Double acting opposed piston (front), and double acting parallel piston (rear). Front shocks mounted on top of frame front cross-member, and rear shocks mounted on brake backing plates.

Filling Shock Absorbers: Remove filler plugs and add fluid until it overflows, using only G.M. or Delco Shock Absorber Fluid. Install plugs loosely to exclude dirt and bounce front or rear of car up and down to force air out of cylinders. Repeat addition of fluid until no more fluid can be added (front shock); or until fluid level is 1/2" to 23/32" below filler openings (rear shocks). *NOTE*—Air space is provided in cover of front shocks, but fluid level must be below filler opening on the rear shocks. Shock Absorber Filler Gun KMO-1026 should be used to fill rear shocks, and then apply Adapter J-1611 to gun to suck out surplus fluid.

Removal (Front Shock Absorber): Place jack under lower control arm, raise wheel off floor and remove tire and wheel assembly. Remove pivot pin bushing clamp bolt in upper control arm, then remove both pivot pin bushings from upper control arm, and remove rubber seals. Loosen clamp bolt in knuckle support and remove pivot pin, using 1/4" Allen wrench. ***(NOTE—Tie steering knuckle support to upper control arm to prevent damage to brake hose.)*** Remove the three shock absorber attaching bolts. The outer bolt (located at upper end of chassis spring) may be removed with a socket wrench and an extension through opening in lower control arm spring seat.

Installation—Reverse the removal procedure and check camber, caster, and toe-in.

LOWER CONTROL ARM ASSEMBLY: (Removal)—Remove chassis front spring and remove lower control arm assembly from frame front cross member.

Bushing & Shaft Removal & Installation—Unscrew bushings and remove shaft from control arm. Check distance between inner ends of control arm. Distance should be 11¼" ± ¼", from inside to inside. Install a rubber seal over each threaded end of new control arm shaft, with large ball ends of seals outward toward ends of shaft. Insert one end of shaft with seal in place in one control arm end and force opposite end of shaft into other control arm end. A piece of wood approximately 1¼" x 2½" x 24" long can be used as a pry. Fasten control arm securely in vise close to one end to prevent springing or distortion. (NOTE—Apply a liberal amount of white lead or Lubriplate to both bushings before installing). Start first bushing on shaft and into control arm at same time. Turn bushing until head is against arm and tighten to 100 ft. lbs. torque. Center shaft between arms and install second bushing in same manner first bushings were installed, turning shaft as required to thread bushing so that no binds exist.

Lower Control Arm Assembly Installation: Before installing lower control arm and shaft assembly, turn shaft to locate the bolt holes at both ends so they are equally distant from inside surface of control arms, then bolt shaft to frame front cross-member. Install chassis front spring and other parts. Check and adjust front end alignment.

UPPER PIVOT PIN & BUSHING REPLACEMENT: (Removal)—Place jack under lower control arm, raise wheel off floor, and remove wheel and tire assembly. Remove pivot pin bushing clamp bolt in upper control arm, then remove both pivot pin bushings from upper control arm, and remove rubber seals. Loosen clamp bolt in knuckle support and remove pivot pin using a ¼" Allen wrench.

Installation—Hold knuckle support in line with hole through control arm and screw pivot pin into knuckle support, with adjusting wrench hole in pin toward split side of control arm. Turn pivot pin until large diameter section is centralized in knuckle support and tighten clamp bolt. Install rubber seals in both ends of pivot pin. Centralize knuckle boss in upper control arm yoke and start the externally threaded bushing on threads of pivot pin and into threads of control arm. Start the plain (grooved) bushing on threads of pivot pin, then turn until hex is just clear of control arm, then install and tighten clamp bolts. Check and adjust front end alignment.

1954-55 BUICK

All Series (1954-55)

►CHANGES & CORRECTIONS

►*STABILIZER BAR INTERFERENCE CORRECTION:* If water outlet hose on radiator contacts the stabilizer bar, insert a spacer under left hand stabilizer bracket to provide a minimum of 3/16" clearance between hose and stabilizer.

►*1955 LOWER CONTROL ARM OUTER PIVOT PIN & BUSHING POSITION CHANGE:* Head of bushing has been reversed so it will be toward front of car on right side, and toward rear on left side.

►*1955 BRAKE PIPE INTERFERENCE WITH UPPER CONTROL ARM CORRECTION:* A clip, Part No. 1334584 should be installed over brake pipe and secured to right frame side rail to hold brake pipe away from upper control arm. Bend pipe away from contact with control arm.

DESCRIPTION: New design with Direct Acting Shock Absorbers and Upper Support Arm pivoted on bracket shaft mounted on frame front cross-member as follows:

Front Shock Absorbers—Delco direct acting hydraulic type located within the coil springs. Upper end is mounted in tower bracket on frame cross-member (bayonet type end with rubber grommets in bracket), lower end is bolted to bracket bolted on underside of spring seat on lower support arm ("eye") type with rubber grommets on mounting bolt). Shock absorbers are interchangeable from right-to-left and can be removed and installed without disturbing suspension.

►*CAUTION—Shock absorber calibrations differ in some models and are not interchangeable from one car to another.*

Upper Support Arm—New assembly (furnished with shaft, bushings, and dirt seals) mounted at inner end on frame cross-member by two bolts in pivot shaft. Shaft and bushings can be replaced separately.

CHECKING & ADJUSTING: Check front wheel bearings, wheel runout, tire inflation, and front end trim dimensions, and see that car is at curb weight before checking front end alignment.

Tire Inflation—24 lbs. cold (after standing for more than 3 hours or driven less than 1 mile), **26 lbs.,** (after car driven more than 3 miles at less than 40 MPH), **28 lbs.** (after car driven more than 3 miles at more than 40 MPH).

Trim Dimension (Front Springs): Before measuring, bounce both ends of car up and down several times to make sure there is no bind in suspension members, and to let springs take a natural position. When car is at rest, measure the trim height between top side of lower control arm and underside of frame cross-member (at bumper bracket). Trim dimension should be within limits shown in table below and lower control arm heights should be same on both sides of car.

►**Trim Dimension Correction**—If trim dimension is less than specified, or additional height is required to prevent "bottoming", install additional spring insulators, divided between upper and lower ends of spring. If more than three additional shims required, replace the spring. NOTE—New springs should not increase the trim dimension more than 1" over specified maximum limit.

CONTINUED ON NEXT PAGE

1954-55 BUICK (C nt.)

Front Trim Dimensions

46C 56C, 76C, 100	3½-4"
All Other Models	3¾-4¼"

Kingpin Inclination: 0° crosswise with 7/8° camber Not adjustable.

Caster· Neg ¼° desired (Limits Pos ½° to Neg ¾°) Both sides of the car should be equal within ½°

Adjustment—Remove lubricant fitting from bushing at outer end of upper support arm (front bushing right side, rear bushing left side), loosen clamp bolt in upper end of knuckle support, use Allen wrench inserted through lubricant fitting hole and turn pivot pin to adjust caster *CAUTION*—Camber will be changed unless pivot pin rotated in complete turns only—check camber after adjusting caster

Camber· Pos 3/8° desired (Limits Pos 7/8° to Neg 5/8°) Both sides of the car should be equal within ¾°

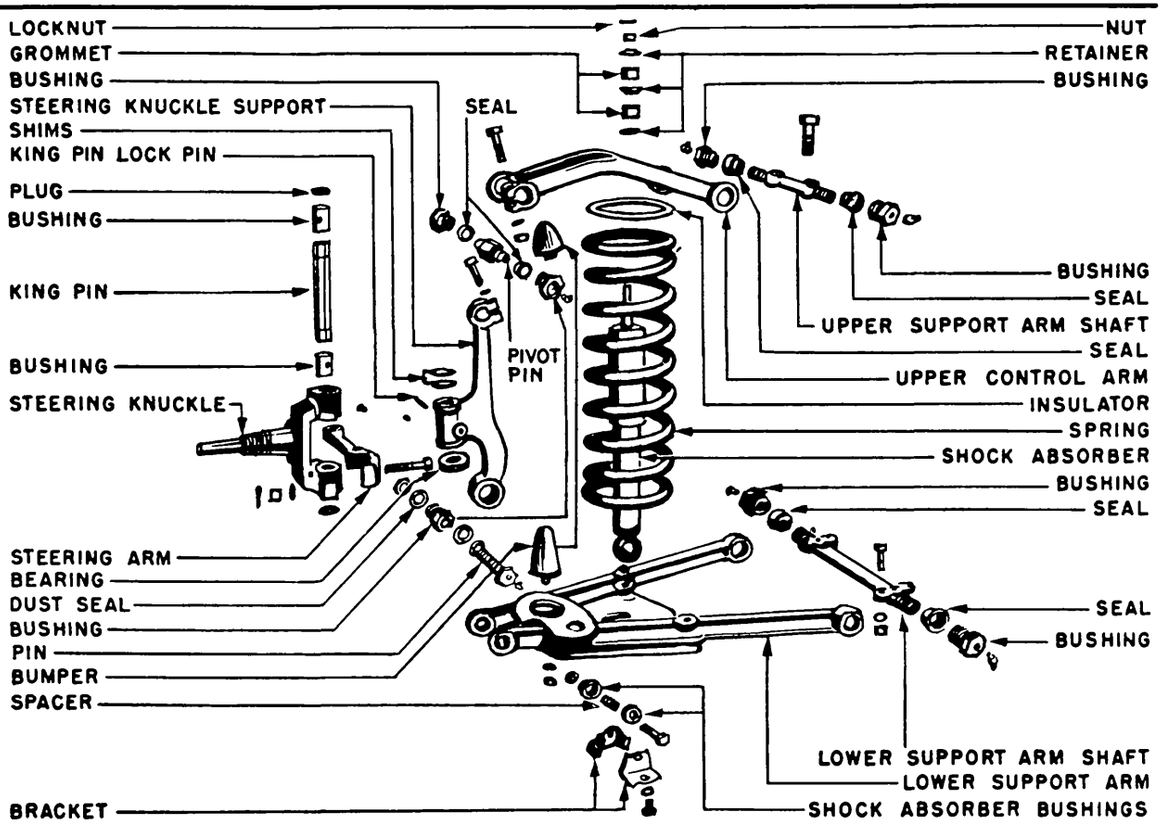
Adjustment—Adjust in same manner as Caster (above) except that eccentric pin should be turned only slightly from point where correct caster secured (entire range of adjustment secured in ½ turn)

To -In: 0" to 1/16" (1954) 1/16" to 1/8" (1955)

Adjustment—Loosen clamp bolt at each end of adjusting sleeve at outer end of **each tie rod,** turn each adjusting sleeve equally to adjust toe-in *NOTE*—Threads at each end of the sleeve should be equal and slots in sleeve and clamp should be aligned

T e-Out n Turns· Inner wheel turns 22½° ±¾° with outer wheel turned 20° No adjustment

►*DYNAFLOW CARS (WITH POWER STEERING) NOTE A special shim, Part No 1290142, is used on the upper end of LEFT front spring between spring and insulator*



►*REAR SPRING NOTE—See "Buick Rear Suspension" in Rear Axle S ction for standard and special rear springs*

Front Spring Application

S ri s	Standard	Air Conditioned
40, 60 (1954 Synchro-mesh)	1165046①	1165048
40, 60 (1955 Synchro-mesh)	1167272④	1165048
50 (1954 Synchro-mesh)	1165047②	1165049
50 (1955 Synchro-mesh)	1167273②	1165049
40, 60 (1954 Dynaflow)	1165047③	1165049
40, 60 (1955 Dynaflow)	1167273②	1165049
50 (1954-55 Dynaflow)	1165048③	1165050
70 (1954-55 Dynaflow)	1165049	1165050
100 (1954)	1165049	

①—No 1165047 200 lb overload (Except Series 40 Convertible & Series 60 Estate Wagon)
②—No 1165048 200 lb overload
③—No 1165049 200 lb overload
④—No 1167273 200 lb overload (Except Series 40 Convertible & Series 60 Estate Wagon)

FRONT SPRING REPLACEMENT (Removal): Place jack under lower control arm and raise sufficiently to remove wheel Disconnect stabilizer link from lower control arm and outer end of tie rod from steering arm Remove shock absorber and remove lower pivot pin nut, pivot pin nut, pivot pin, lock washer, and dust seals Support car frame with another jack, then slowly lower jack under lower control arm, and remove spring

1954-55 BUICK FRONT SUSPENSION

Installation· Before installing front spring, check the spring part number to make sure it is the correct spring (See "Front Spring" Table above). Make sure that rubberized fabric spring insulator is around spring centering flange on frame and is in good condition. Place one end of spring over centering flange, and as lower control arm is raised, position lower end of spring so that end coil seats in recess in spring seat Support lower control arm on a jack Slip lower pivot pin dirt seals over outer ends of lower control arm Centralize lower end of knuckle support between outer ends of lower control arm, then install lower pivot pin and lock washer from front side and tighten securely Install and tighten nut Snap dirt seals into place over pivot pin Connect tie rod outer end to steering arm, and connect stabilizer link to lower control arm (NOTE—When stabilizer rod nut is tightened, the overall length of each grommet assembly should be 1 11/16' Adjust nut as necessary to obtain this dimension) Reinstall shock absorber and wheel Adjust front end alignment

SHOCK ABSORBER REPLACEMENT Not necessary to disturb front suspension assembly

R m val· Hold upper mounting stem with a wrench, remove palnut and retaining nut (on top of shock absorber mounting bracket in engine compartment), lift off upper retainer and rubber grommet Remove bolts and lockwashers attaching lower mounting bracket to underside of spring seat on lower support arm, pull shock absorber and mounting bracket assembly down through opening in spring seat Do not lose retainer and grommet on shock absorber mounting stem To remove shock absorber from lower mounting bracket, remove pivot bolt and nut, pull bracket off, remove rubber grommets and spacer from shock absorber eye

Installation: Check to make sure the correct shock absorber is being installed *(See "Shock Absorbers" on Car Model page)*, then reverse the removal procedure as given above

UPPER SUPPORT ARM REPLACEMENT (Removal)· Remove generator and engine front mounting nuts, and raise engine just enough to allow removal of support upper arm shaft bolts Remove pivot pin and bushings from support arm by taking out the pivot pin clamp bolt and turning bushings out of support arm Remove rubber seals Loosen clamp bolt in knuckle support and remove pivot pin, using a ½' hex Allen wrench Remove support arm shaft attaching bolts and remove support arm assembly from car Unscrew shaft bushings and remove shaft and seals from arm

CONTINUED ON NEXT PAGE

1954-55 BUICK (C nt.)

Installation: (*CAUTION—Before installing any new parts, check the distance between the two shaft bosses at inner end of support arm assembly—this distance should be 6 5/16" ± .020").* Install a rubber seal over each end of upper arm shaft, with large or bell end of seal outward. Insert one end of shaft with a seal, in one end of upper arm, and force other end of shaft into opposite end of arm. Fasten upper control arm securely in vise (close to one end of arm to avoid spring or distortion). Apply a liberal amount of white lead or Lubriplate to both bushings before installing. Start first bushing on shaft and into upper support arm at same time. Turn bushing until head is tight against arm, then tighten to a minimum of 100 ft. lbs. torque. Center the shaft between ends of arm and install second bushing in same manner as first bushing, tightening the second bushing so that no binding exists. Before installing support arm, turn the shaft to locate the bolt holes equally distant from ends of arm, then bolt shaft to frame front front cross member. Lower engine and tighten front mounting nuts. Reinstall upper pivot assembly as follows: Hold knuckle support in line with hole through support arm and screw pivot pin into knuckle support, with adjusting wrench hole in pin toward split side of control arm. Turn pivot pin until large diameter section is centralized in knuckle support and tighten clamp bolt. Install rubber seals on both ends of pivot pin. Centralize knuckle support boss in support upper arm yoke and start the externally threaded bushing on threads of pivot pin and into threads of control arm. Start the plain (grooved) bushing on threads of pivot pin, then turn the opposite bushing up tight. Turn plain bushing until hex is just clear of arm, then install and tighten clamp bolts. Check and adjust front end alignment.

LOWER CONTROL ARM REPLACEMENT (Removal): Remove front chassis spring, then remove lower control arm assembly from frame front cross member.

Bushing Replacement: (*CAUTION—Before installing any new parts, check the distance between the two shaft bosses at inner end of support arm assembly (this distance should be 11¼" ± 1/32").* Install a rubber seal over each threaded end of new control arm shaft, with the large or bell ends of seals outward toward ends of shafts. Insert one end of shaft with a seal in place in one control arm end and force opposite end of shaft into other control arm end (a piece of wood approximately 1¼" x 2½" x 24" can be used as a pry). Fasten control arm securely in a vise (close to one end of arm to avoid spring or distortion). Apply a liberal amount of white lead or Lubriplate to both bushings before installing. Start first bushing on shaft and into control arm at same time. Turn bushing until head is tight against arm and tighten to 100 ft. lbs. torque. Center shaft between arms and install the second bushing, turning shaft as required to thread into bushing so that no binding exists.

Installation: Before installing lower control arm and shaft assembly, turn shaft to locate bolt holes at both ends so they are equally distant from the inside surface of arms, then bolt shaft to frame front cross member. Install chassis spring and other parts, and check and adjust front end alignment.

STEERING KNUCKLE REPLACEMENT (Removal): Remove front wheel with hub and drum assembly. Remove brake backing plate and steering arm from steering knuckle (Do not disconnect brake hose but support backing plate out of way to avoid strain on hose). Drive out kingpin lockpin. Remove upper welch plug from knuckle by piercing with a sharp pointed punch and prying out. Drive kingpin down and out, which will drive lower welch plug from knuckle. Remove thrust bearings and shims.

Installation: Reverse removal procedure and use shims as required between knuckle support and upper boss of knuckle to provide .003" endplay of knuckle on support. Use new welch plugs at each end of kingpin. Check and adjust front end alignment.

1941-49 CADILLAC

Cadillac V8, All Series (1941 to 1949)

DESCRIPTION: Independent linked parallelogram type with coil springs.

ADJUSTMENT: Before making adjustments, check wheels for balance, run-out and tracking; check wheel bearing adjustment and see that all front end parts operate freely.

Tire Inflation—Check tires and inflate as follows:

Tire Inflation Pressure

60S, 61, 62 (1946-48)	28 lbs.
60S, 61 62 (1949)	24 lbs.
67, 75 (1941-42)	(Frt) 24, (R) 32 lbs.
75 (1946-49)	(Frt) 24, (R) 32 lbs.
76, 86 Comm'l (1948-49)	(Frt) 34, (R) 36 lbs.

Wheel & Tire Run-Out—Check wheels for run-out and mark high point on tire. Place this mark vertically (at top of wheel) when checking Toe-in and Toe-out, horizontally (at one side of wheel) when checking Caster, Camber and Kingpin Inclination.

Kingpin Inclination—Crosswise inclination with specified Camber as follows:

Kingpin Inclination

All Models (1941-49)	5°51' (0° Camber)

Caster: As shown below. Must be equal on both sides of car within ½°. NOTE—Negative figures indicate Reverse Caster.

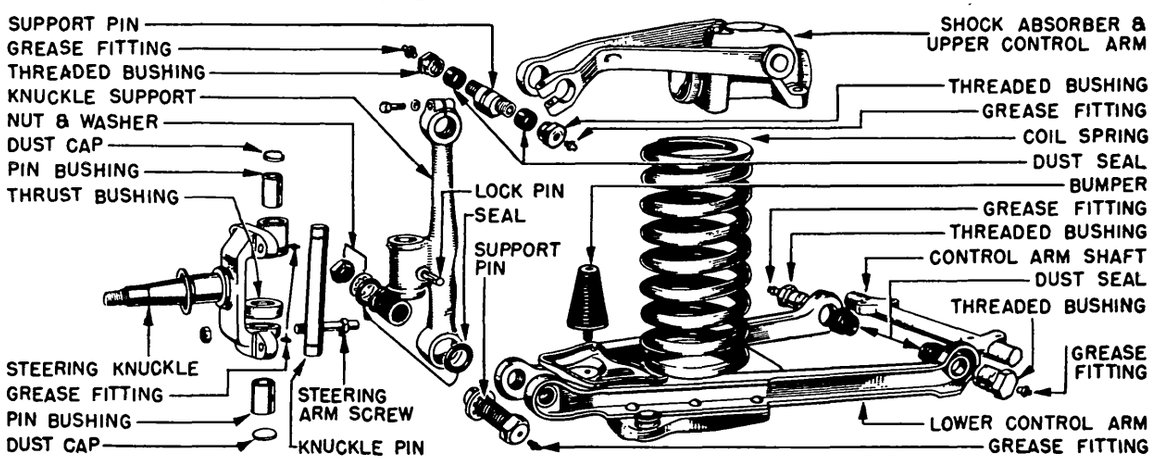
Caster Specifications

1941-47 (All Models)	Neg. 1¾° to Neg. 2¾°
1948-49 (All Models)	Neg. ½° to Pos. ½°

To Adjust (All Series)—Loosen the clampscrew in upper end of knuckle support, remove lubrication fitting in front bushing of upper control arm, insert Allen wrench, Tool J-720, through lubricant fitting hole, turn eccentric upper support pin in complete turns only, clockwise to increase caster, counter-clockwise to decrease caster. IMPORTANT—Camber will be disturbed unless pin turned in complete turns only.

Caster Adjustment Note—If correct caster adjustment cannot be secured within limits of turning of the upper support eccentric pin, greater range of adjustment can be secured by disconnecting lower support arm inner mounting shaft at frame crossmember and turning shaft in arms (screwing shaft to rear which will move support arms forward increases Caster).

Camber: 0° ± ⅜°, and equal within 1°.



To Adjust (All Series)—Same as for caster adjustment, except that entire adjustment secured within ½ turn of eccentric pin.

Toe-in:—Should be 0-1/16" (car in motion), 1/32-3/32", car at rest) for all models. Measure with 'high' point of tire run-out in vertical position at top of wheel.

To Adjust (All Series)—Loosen the clamp bolts and turn tie rod adjuster (at wheel end of each tie rod) equally on both sides of car (to maintain correct position of steering gear).

Steering Geometry (Toe-out on turns):—With outer wheel turned exactly 20°, inner wheel should be turned exact amount shown in table below. Check

CONTINUED ON NEXT PAGE

1941-49 CADILLAC FR NT SUSPENSION

1941-49 CADILLAC (C nt.)

for bent steering arms if incorrect. NOTE—On 1946-49 cars, inner wheel turning angle differs for right and left turns as shown.

1941-49 Steering Geometry

Car Model	Inner Wheel① Right Turn	Left Turn
60S, 61, 62, 63 ('41-42)	24°42'	25°25'
67, 75 ('41-42)	23°6'	24° 7'
67, 75 Comm'l ('41-42)	23°6'	24° 7'
60S, 61, 62 ('46-48)	24°42'	25°25'
60S, 61, 62 (1946-49)	24°42'	25°25'
75, 75 Comm'l (1946-47)	23°6'	24° 7'
75, 76 Comm'l (1948)	23°6'	24° 7'
75, 86 Comm'l (1949)	23°6'	24° 7'

①—With outer wheel turned exactly 20°.

SERVICING (1940-49 Cars): Lower Control Arm and Knuckle Support Pin—Control arm mounted on inner frame bracket shaft by threaded bushings (bushings threaded on shaft and in control arms) with rubber seals on shaft. Shaft can be removed from control arms after bushings have been removed. Support pin at outer end of control arm is threaded through both control arms and bushing in lower end of knuckle support and has nut on rear end. Rubber seal is installed on support pin at front end of bushing (between knuckle support and front control arm).

Upper Control Arm Support Pin—This eccentric pin is threaded in bushings in each upper control arm and in upper end of knuckle support (rear bushing is threaded type and is screwed in control arm, front bushing is plain type and is locked in control arm by clamp bolt). A clampscrew in the upper end of the knuckle support locks the pin in the support to maintain caster and camber setting.

SPRINGS: Part number is stamped on end coil of each spring. When installing springs see that insulator at top and bottom of each spring.

1946-47 Spring Specifications

Car Model	Part No.	Color Mark
75 Comm'l	1428429	Yellow
60S, 62	1428433	Orange
61	1428432	None
75	1428434	Pink
61, 62 exc. Conv't	1428433	Orange
62 Conv't	1428434	Pink
60S, 75	1428434	Pink
76 Comm'l	1428429	Yellow

1948-49 Spring Specifications

Car Model	Part No.	Color Mark
61, 62 exc. Conv't	1455406	None
60S, 62 Conv't	1455407	Gray
75	1428434	Pink
86 Comm'l	1428429	Yellow

Spring Heights—4½-5¼" measured from center of lower rivet on front side of bumper bracket on frame cross-member to top of lower spring seat adjacent to lower bumper. Springs on both sides of car should be equal within ⅜". Correct by installing spacer under low spring.

1950-55 CADILLAC

All Series (1950-55)

►CHANGES, CAUTIONS, CORRECTIONS

►*1954 DRAG LINK TO TIE ROD INTERFERENCE CORRECTION:* This interference is on the right side and is generally caused by the idler arm being too high. Correct by loosening the idler arm support-to-frame screws and rotate the idler arm down and forward as far as possible, then tighten screws. In addition, the idler arm should be backed out of its bushing in the support a total of 2½ turns, instead of the 1½ turns previously recommended.

►*1954 COMMERCIAL CHASSIS FRONT WHEEL RUBBING FENDER CORRECTION (On Extreme Right or Left Turns):* Check the special steering arm-to-knuckle screw which incorporates the wheel stop. A 1/16" washer should be between the head of the screw and the steering knuckle. If this washer in place, the trouble lies in excessive weight on the front springs and can be corrected by installing front spring shims, Part No. 1457838 on TOP of each spring, or installing heavy duty front springs. To determine if heavy duty springs are required, proceed as follows: Weigh front end of car (with total load carried at time of complaint, and with vehicle level). If weight exceeds 3200 lbs., heavy duty springs are indicated. These springs, Part No. 1460998 are available for service replacement. *NOTE—Heavy duty Rear Springs, Part No. 1460931 are also available if rear end weight exceeds 3900 lbs., under the same conditions as above.*

►*1954 KINGPIN LUBRICATION FITTING INTERFERENCE CORRECTION (Fitting Strikes Steering Knuckle Support and is Damaged):* If difficulty is encountered getting grease through this fitting, remove the fitting and counterbore the original tapped hole to a depth of 3/32"-1/8", using a ½" drill ground at 140° included angle. Run a ¼"-28 tap through to clean the threads, then install a new fitting.

►*1955 FRONT WHEEL BEARING NOISE CORRECTION:* On cars between Engine No. 33512 and 34344, there is the possibility that oversize bearing cones were installed. Check bearing cone to shaft clearance as the oversize cone will have in excess of 1/32" clearance.

►*1955 EL DORADO FRONT & REAR SPRING PRODUCTION CHANGE:* At Engine No. 41150 the overall height of the Eldorado has been lowered 1" by the use of different springs, as follows: No. 1461008 (Front), No. 1460932 (Rear).

►*1955 STABILIZER LINK PRODUCTION CHANGE & INSTALLATION CAUTION:* At Engine No. 70000, a shorter link (6⅜"), and spacer (2½") replaced the early link (7"), and spacer (3⅛"). Either the short or long link may be used but it is important that links on both ends of the front stabilizer be of the same length.

►*1955 FRONT COIL SPRING PRODUCTION CHANGE:* Later cars do not have a spring lower insulator and the front springs have been increased slightly in length. When installing the later type front spring, the lower insulator should be discarded.

►*FRONT SPRING NOISE CORRECTION:* If click, scrape or grind noted (particularly on low speed brake application) correct as follows:

Seating Spring in Upp r Seat—Drive car at moderate speed and apply brakes sharply (will cause spring to center itself in upper seat) or use pry bar to push upper end of spring onto its seat.

Insufficient Clearance at Lower Cross-Member flanged opening—After spring seated properly, check clearance between spring and lip of flanged opening in lower cross-member. Correct by bending lip on flange (CAUTION—do not use heat and bend lip only in area where contact occurs).

DESCRIPTION: New design independent "parallelogram" type with coil springs and direct acting shock absorbers mounted independently of upper control arm. Upper control arm is new design mounted on frame bracket shaft in same manner as lower control arm. Shock absorbers can be removed and installed without disturbing upper control arm assembly.

ADJUSTMENT: Before making adjustments, check tire pressures (see data below), front wheel bearing adjustment, check for run-out and high spots (3/64" maximum in each case), wheel and tire balance, and spring height. Make certain that entire suspension system operates freely without binding or excessive play, place wheels in straight-ahead position and see that car is at curb weight. Then check and adjust following points in order:

Tire Inflation—(60S, 61, 62) 24 lbs. front and rear, (75) 28 lbs. front and rear, (86 Comm'l) 24 lbs. front, 30 lbs. rear.

Full Spring Height—See that car is at curb weight (full tank of gasoline, no load in trunk or car), normalize spring position by working bumper up and down and release slowly so that car assumes normal position. Then check distance from center of front lower rivet on rubber bumper bracket on frame to top surface of lower control arm spring seat directly below this rivet. Correct heights are listed in table below and should be equal on both sides of car within ⅜". Correct height by installing shim between bottom of spring and spring seat on low side of car or replace springs. See Spring data.

►***CAUTION—Do not replace springs to correct excessive height during first 2000 miles (springs settle considerably during this period).***

1950-53 Front Spring Heights

Car Model	Spring Height
60S, 61, 62 Sedan	4¾-5½"
75 Sedan	5⅜-6⅛"
86 Comm'l	5⅜-6⅛"

1954-55 Front Spring Heights

Car Model	Spring Height
All Models (Exc. 75 & 85)	4½-5¼"
75	5 3/8-6 1/8"
85 (Commercial)	5½-6¼"

Rear Spring Height—Measure at point 3¼" forward from center of lower rivet in frame side bar above rear axle (make chalk mark on frame at this point). Measure vertical distance from top of spring U-bolt to chalk mark on frame. Correct height as listed in table below and should be equal on both sides of car within ½".

C NTINUED ON NEXT PA E

1950-55 CADILLAC (C nt.)

1950-53 Rear Spring Heights

Car Model	Spring Height
60S, 61, 62 Sedan	5¾-7⅛"
75 Sedan	6-7½"
86 Commercial	6-7½"

1954-55 Rear Spring Heights

Car Model	Spring Heights
All Models (Exc. 75 & 85)	8¾-9½"
75	10-10¾"
85 (Commercial)	9 5/8-10 3/8"

Front Wheel Run-out—Mark point of maximum run-out on tire, turn wheel so that this mark is at front or rear when checking Caster and Camber, at top or bottom when checking Toe-In and Toe-Out.

Kingpin Inclination: 5°51' crosswise, all models.

Caster: 0°±½° (Neg. ½° to Pos. ½°) (1950-53), 0° to Neg 1° (1954-55). Must be equal on both sides of car within ½°.

Adjustment—Loosen clampscrew in upper end of knuckle support, use special wrench, Adjusting Tool KMO-366 or J-4691 (see Tool Note), to turn eccentric bushing on pivot pin. (NOTE—hexagonal head on bushing for wrench engagement located at rear end of bushing on early 1950 cars, front end on later cars). Turn eccentric bushing in complete turns only until correct caster secured, tighten clampscrew.

►**Adjusting Tool Note**—KMO-366 is special thin open-end wrench, J-4691 is special "crow-foot" wrench with square drive opening and can be used on all cars (regardless of bushing head location).

►***CAUTION—Camber will be disturbed unless bushing rotated in complete turns only.***

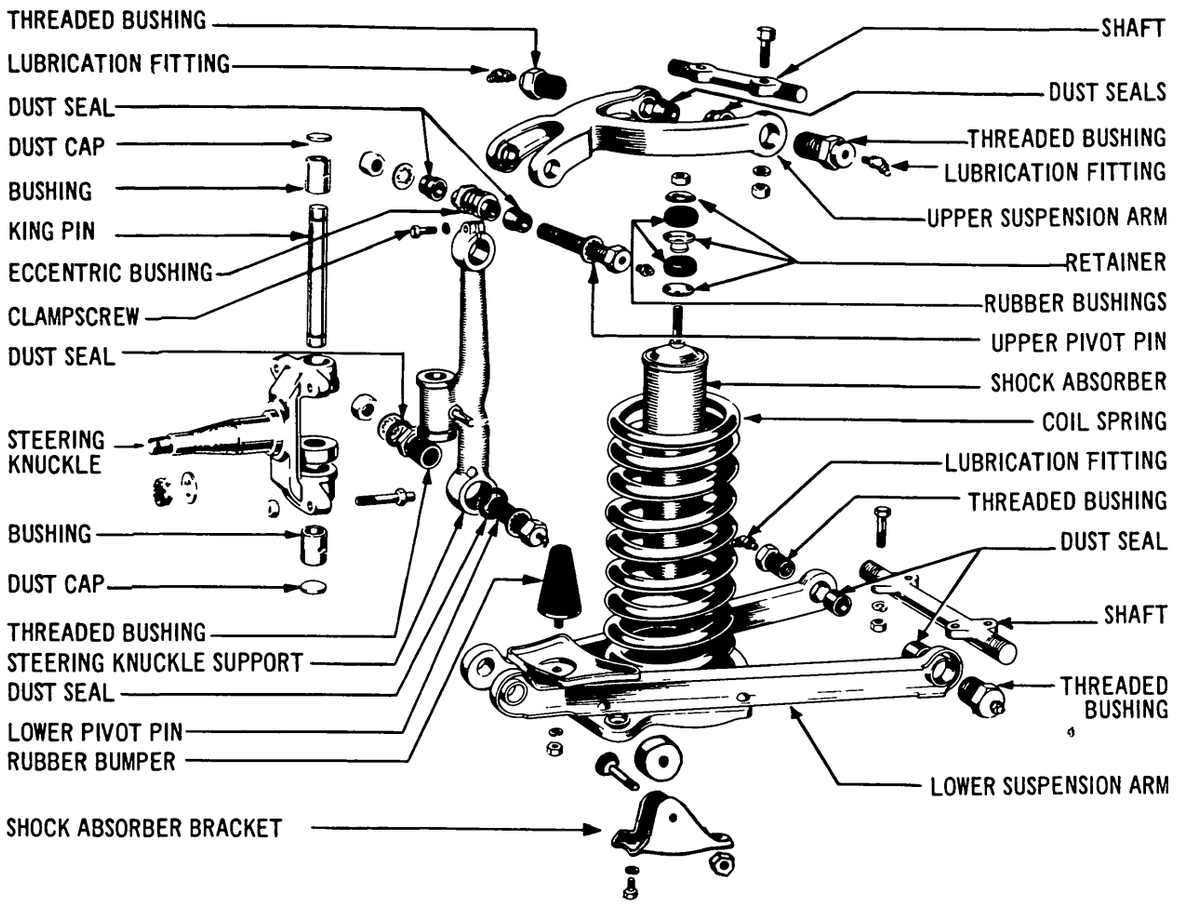
►***ADDITIONAL RANGE OF ADJUSTMENT***—If correct caster cannot be secured within limits of eccentric bushing rotation, additional range of adjustment can be secured by disconnecting lower support arm inner mounting shaft at frame cross-member and turning shaft in the arm (moving shaft to rear will increase positive caster).

Camber: 0°±⅜° (Neg. ⅜° to Pos. ⅜°) and equal on both sides of car within ½° (1950-53). Pos. 3/16° on left wheel, Neg. 3/16° on right wheel desired with limits Neg ⅜° to Pos ⅜° and ¼° to ½° more positive camber on left wheel (1954-55).

Adjustment—Same as for Caster (above). Turn eccentric bushing not more than ½ turn in either direction from point where correct caster is secured.

►***CAUTION—Entire range of camber adjustment secured in ½ turn of the eccentric bushing.***

Toe-In: 1/32-3/32" (1950-53), 3/16-¼" (1954-55) with car at rest. Check with wheels in straight-ahead position and point of maximum wheel run-out vertically up or down



Adjustment—Loosen clampscrews and turn Adjuster at outer end of each tie-rod equally (turning adjuster in direction of forward wheel rotation will decrease toe-in). Tighten clampscrews.

►***CAUTION—Open side of adjuster clamps must be over open side of adjuster when clampscrews tightened.***

Toe-Out on Turns: With outer wheel turned 20°. Inner wheel should be turned as follows:

1950-53 Series—	Left Turn	Right Turn
60S, 61, 62	25°25'	24°42'
75, 86	24°7'	23°6'

1954-55 Series (All)—With outer wheel turned 20°, inner wheel should be 22°40'.

1950-55 CADILLAC FRONT SUSPENSION

SHOCK ABSORBER REPLACEMENT: ***Not necessary to disturb Front Suspension Assembly.*** Remove upper retaining nut, retainer, and rubber grommet from upper spring seat tower in engine compartment (NOTE—use wrench on squared upper stem of shock absorber to prevent it turning while loosening nut). Remove two bolts retaining lower shock absorber bracket on lower face of spring seat on lower control arm, then withdraw shock absorber and bracket assembly through hole in spring seat. Remove lower bracket by taking off retaining nut, grommets and retainers from shock absorber stem.

►**Installation Note**—See illustration for correct assembly of grommets and retainers on shock absorber stem. Use wrench on squared upper stem of shock absorber to prevent unit turning while tightening retaining nuts.

COIL SPRING REPLACEMENT: Support front end of car on jack under center of front cross-member, use second jack under suspension arm to support spring which is being removed. Disconnect front stabilizer link on same side of car. Remove shock absorber (see data above). Remove nut on lower pivot pin, unscrew pin from lower control arm and knuckle support. Lower jack under suspension arm until spring tension relieved, remove jack, lift spring out. Install spring by reversing this procedure.

►**Spring Installation Caution**—Install spring with open (tanged) end upward and seated in upper seat so that tang parallel with raised area on cross-member and visible through correct hole in the cross-member (right front spring tang visible through rear hole, left front spring tang visible through front hole). Hold spring in this position while raising lower suspension arm, drive or pry bottom of spring into its seat on lower arm (will not seat freely with arm lowered and spring fully extended).

FRONT STABILIZER REMOVAL & INSTALLATION: Disconnect link by removing nut on lower end and withdrawing link bolt from above (CAUTION—note location of retainers and grommets at upper and lower ends of link and replace in exact same order). Remove bolts from two frame mounting brackets,

CONTINUED ON NEXT PAGE

1950-55 CADILLAC (Cont.)

remove stabilizer. Remove rubber bushings from stabilizer brackets and bar (these bushings serviced separately). Install stabilizer by reversing above procedure.

SPRINGS: Part number is stamped on end coil and springs are color-marked for identification.

1941-48 CHEVROLET

All Passenger Car Models (1941-48)

▷EXCESSIVE BUMPING CORRECTION (Cars operated on rough roads or in heavy service): Check front end to make certain that the lower control arm rubber bumpers are in place and replace any missing bumpers. Install heavy duty shock absorbers, or heavy duty front springs (see Springs).

▷SUSPENSION UNIT REMOVAL NOTE—Entire suspension unit assembly (consisting of frame crossmember and both control arm assemblies) may be removed from car as an assembly for overhaul or replacement if desired. See Service data below.

DESCRIPTION: "S.L.A." (short and long arm) type. Shock absorbers are 'parallel cylinder' type (unit with upper control arms).

CHECKING & ADJUSTMENT:—Check first:

Tire Inflation: Check for correct pressures before checking front end specifications:
Std. 6.00x16 Tires (Front) 26 lbs. (Rear) 28 lbs.
Optl. 6.70x15 Tires (Front & Rear) 24 lbs.

Wheel Runout—Check and adjust front wheel bearings. Check wheel for tire and rim runout and eccentricity. Mark tire midway between high and low spots (mean point) and place this mark at top (vertically) when checking Camber, at side (horizontally) when checking Toe In.

Frame Height—Install special gauges at front and rear ends of car to level frame when checking or bounce car up and down several times to insure that it is in normal position. See Spring data for spring height check to detect sagging or unequal springs.

NOTE—Make all checks with car weight on wheels

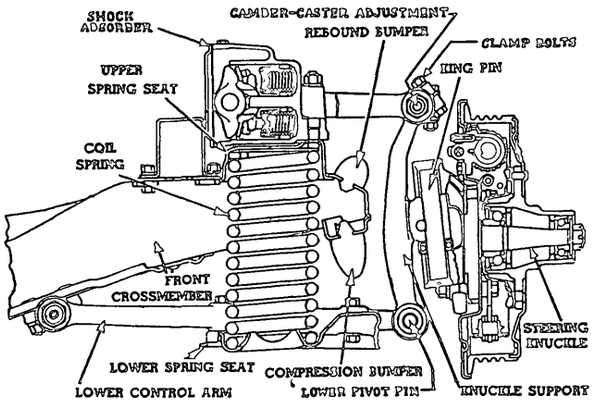
Kingpin Inclination:—4¾° plus or minus ½°.

Caster:—0° plus or minus ½°. Adjusted by turning knuckle support eccentric upper pivot pin (same adjustment same as for Camber (below).

Camber:—Neg. ⅛° ± ½° (wheel tilts in at top).

Adjustment—Remove lubricant fitting on knuckle support upper pivot pin front bushing, loosen clamp bolt in upper end of knuckle support which clamps pivot pin. Insert ⅛" Allen wrench through lubricant fitting hole in bushing to engage pivot pin, turn pivot pin clockwise to increase caster, counter-clockwise to decrease caster (pin is eccentric and this same movement will change Camber from minimum to maximum every half turn of the pin) until both caster and camber are correct within limits given above, tighten clamp bolt and replace lubricant fitting. One half-turn of pivot pin will change caster angle 39' and change camber angle from 0° to 1°2' depending upon position of pin.

Toe-In: (1939-42) 0" to 1/16" (1946-48) 0" to 1/8".



Adjustment—Loosen the clamp bolt at each end and turn left hand (short) tie rod. When tightening clamp bolts, make certain that both tie rod ends are in alignment with the ball studs.

NOTE—Right hand (long) tie rod is not adjustable.

Steering Geometry (Toe out on Turns)—Outer wheel turned in 20°, Inner wheel turned 24° plus or minus 2°. Not adjustable (replace steering arm).

SERVICING: Suspension Unit Assembly Removal—Remove Front Fenders, Radiator, and Radiator Grille Assembly as a unit (see Chevrolet Shop Notes Car Model Section for data). Remove front bumper disconnect stabilizer from frame horns, remove pitman arm from steering gear. Take out bolts holding front cross-member to frame side rails, slide suspension unit assembly off over frame side rails at forward end. Install in same manner.

Upper Control Arm Pivot Pin:—To remove pin, raise car with chain hoist, place jack under spring seat so that it takes weight of car, remove wheel and tire assembly. Unscrew rear (threaded) bushing, remove front bushing clamp bolt, remove bushing. Loosen clamp bolt in upper end of knuckle support, unscrew pivot pin (use Allen wrench).

Assembly—Place Neoprene seal over end of each upper control arm (so seals will be out of the way while installing pivot pin). With knuckle in upper arm yoke, enter pivot pin through eye in control arm and screw pin in knuckle support (with Allen wrench socket hole in pin toward front of car) until larger diameter center section is centered in knuckle support. Hold knuckle support centered in control arm, thread rear bushing in control arm eye and on pivot pin, tighten bushing securely and make certain that support still centered in control arm yoke. Screw front bushing in on pivot pin until clearance between head of bushing and face of control arm is .020-.040". Use a wire hook to pull Neoprene bushings down over the ends of control arm so that they seat on pivot pin. Install front bushing clamp bolt. Adjust Caster and Camber (see instructions above).

Lower Control Arm Pivot Pin:—To remove, raise car install jack stand under inner side of lower spring seat, remove wheel and tire assembly, unscrew pivot pin (use socket wrench, remove pin through front arm), turn wheel to extreme outward position (will prevent knuckle support moving out at bottom), install block between upper control arm and cross-member to raise lower end of knuckle support clear of control arm yoke, unscrew bushing.

Assembly—Screw bushing securely in knuckle support from front end. Place new Neoprene seal on end of front lower control arm (so that it will be out of the way while installing pivot pin), place second seal on exposed end of bushing at rear of knuckle support. Thread pivot pin through front control arm, knuckle support bushing, and rear control arm while holding knuckle support centered in control arm yoke (if threads on pin and control arms do not index correctly, use 'C' clamp to compress arms slightly until pin enters rear control arm). Tighten pin securely. Pull Neoprene

CONTINUED ON NEXT PAGE

1941-48 CHEVROLET (Cont.)

seals down so that they are seated on pivot pin.

Lower Control Arm Shaft (Frame Support):—To remove, disconnect stabilizer link at lower spring seat, remove front spring (see Spring Removal below), remove lower control arm pivot pin (see directions above), remove lower control arm assembly. Place assembly in vise, remove front and rear control arm shaft bushings. Take out two bolts mounting front control arm, remove arm and shaft.

Assembly (1939-40)—Install retainer cups on ends of shaft with cupped shaped ends out, install new Neoprene seal on shaft next to each retainer, install shaft in control arm assembly with letter 'F' (forged on one bracket) toward front of car, bolt front control arm securely to spring seat (screw pivot pin through both control arm eyes first to maintain alignment while spring seat bolts are being tightened). Hold shaft centered between control arms, screw front and rear bushings on shaft and in control arms, tighten bushings securely.

Assembly (1941-48)—Install Neoprene seal on end of shaft so that seals seat in recess at shoulder on shaft, install shaft in control arm assembly with letter 'F' (forged on one bracket) toward front.

Front Stabilizer Shaft:—To remove, disconnect links by removing nut on upper end of link bolts and withdrawing bolts, then remove bolts from frame mounting brackets. To install stabilizer, make certain that steel spacer installed between frame and bracket, bolt bracket loosely to frame, install links, tighten bolts only with car weight on wheels.

SPRING HEIGHT CHECK: To check spring height, insert steel scale inside spring with upper end of scale against center of upper spring seat, place straight edge diametrically across lower face of lower spring seat (line straight edge up with drain hole in seat). Reading on scale at straight edge should be 9 29/32" plus or minus 1/16" on 1946-47 cars.

Spring Height Correction—Spring height can be increased by installing **not more than two Part No.** 599810 Front Spring Shims between top of spring and upper spring seat. These shims are 1/16" thick.

SPRINGS:—**Removal**—Disconnect stabilizer link from lower spring seat, support weight of car on stand jack at inner side of lower spring seat, remove cotter pins and nuts from lower control arm shaft bracket bolts, drive out bolts and install long drift punch through bolt hole in bracket and cross-member to maintain alignment, raise car with chain hoist to remove spring pressure. Remove jack from beneath lower control arm allowing control arm and spring seat to drop down to free spring.

Assembly—Make certain that spring installed with ground end (flat surface) up and that lower end-coil of spring fits in recess in spring seat. Reverse removal directions given above.

Heavy Duty Springs—Use only for severe operation. Will prevent spring bottoming and provide more clearance at front end. Install No. 5245543 to correct severe bumping, No. 5246233 in extreme cases.

Spring Specifications

Car Model	Color Mark	Part No.
1941-48	Green	3664086
1941-48 (Heavy Duty)	Black	3694210

Spring Shim Note—To compensate for variation in springs, one shim should be used with all springs marked by green dot on top coil, two shims with springs marked by yellow dot on top coil.

1949-54 CHEVROLET

All Passenger Car Models (1949-54)

►**FRONT SUSPENSION UNIT ASSEMBLY REMOVAL:** Entire assembly is mounted on special cross-member bolted to frame side rails and can be removed as a unit for servicing and overhaul by taking out these mounting bolts.

►CHANGES, CAUTIONS, CORRECTIONS

►**LOWER CONTROL ARM ASSEMBLY PRODUCTION CHANGE:** Two types of arms used on 1949 cars can be identified as follows:

First Type—Does not have re-inforced control shaft bushing hole at inner end. Special bushings and locknuts must be used with this arm.

Later Type—Has welded re-inforcement plate on inner face of arm at each control shaft bushing hole (locknuts not used with bushings with this type arm). Replacement arms have burnished threads for bushings and control shaft used with this arm has thread starts matched with those in arm.

NOTE—Second type control shaft can be used with first type control arm and bushings but other parts are not interchangeable.

►*REPLACEMENT PARTS PACKAGE CAUTION*—Different parts packages required for cars with each type control arm as follows:

Service Pkg. No. 3690685
(For First Type Control Arm)

Lower Control Arm Shaft	3687664
Shaft Bushing (2 used)	3687638
Bushing Locknut (2 used)	3687637
Bushing Seal (2 used)	599180

Service Pkg. No. 3693459
(For Later Type Control Arm)

Lower Control Arm Shaft	3691468
Shaft Bushing (2 used)	3691454
Bushing Seal (2 used)	599180

►**UPPER CONTROL ARM SHAFT PARTS & INSTALLATION CHANGE (To correct loosening of shaft in spring tower):** Minimum driving torque when installing this shaft has been raised to 75 ft. lbs. (with lubricated threads) to prevent shaft loosening and turning in tower. **If required installation torque less than 75 ft. lbs., install oversize shaft** (.008" Oversize). Shafts can be identified as follows:

Upper Control Arm Shaft

Size	Part No.	①Identification Mark
Standard		Drill Point
.008" Oversize	3693693	"◎" or "+"

①—In "V" section on rear end of shaft.

DESCRIPTION: New design; independent, linked parallelogram type with direct acting shock absorbers, coil springs, and new type upper control arm (not part of shock absorber assembly). Cross-member on which suspension unit mounted has new "tower type" bracket at each end for spring housing, shock absorber mounting, and upper control arm shaft mounting.

CHECKING & ADJUSTMENT: First check entire front end for excessive play and wear, check steering gear adjustment, wheel bearing adjustment, tire inflation pressure (see data below), wheel balance and run-out (run-out should not exceed 1/16"), then place car on level floor and check front end specifications as follows:

Tire Inflation Pressure: For each type tire (Cold): **Pass. Cars** (6.70x15—4 ply)—24 lbs. frt. & rear. **Station Wagon & Sedan Delivery** (6.70x15—6 ply) 26 lbs. front, 30 lbs. rear.

Riding (Spring) Height: Rock car sidewise several times and allow it to settle, then measure vertical distance from center of pivot pin at each end of lower control arm to floor. Difference between these two measurements should be 1⅝" ± ¼". If difference between measurements less than this amount, or if unequal on both sides of car, install spring shims or replace springs (see Spring data).

Kingpin Inclination: 4° ± ½° crosswise.

Caster: Pos. ½° ± ½°.

Adjustment—Loosen clamp bolt in upper end of knuckle support, remove lubricant fitting from rear bushing at outer end of upper control arm, insert Allen wrench through hole, turn pivot bolt until exact caster setting secured, then adjust camber.

►*CAUTION—Caster adjustment will change camber unless pivot bolt rotated in full turns only.*

Camber: Pos. ½° ± ½°.

Adjustment—After adjusting Caster (above), rotate pivot bolt not more than ½ turn in either direction to secure correct camber. Entire range of adjustment is secured in ½ turn of the pivot bolt.

Toe-In: 0-1/8" (1949-52), 1/4"±1/16" (1953), 1/8"± 1/16" (1954).

Adjustment—Loosen clamp bolts at each end of **left hand tie rod** and turn rod (right hand tie rod is one-piece non-adjustable type), tighten clamp bolts to 8-12 ft. lbs.

►*CAUTION—Align tie rod ends before tightening clamp bolts (ball studs will bind if not aligned).*

Toe-Out on Turns: With inner wheel turned 20°, outer wheel should be turned 17°40'. No adjustment, replace steering arm if incorrect.

SHOCK ABSORBER REPLACEMENT: *Not necessary to disturb Front Suspension Assembly.* Remove nut on shock absorber upper threaded end while holding stem from turning with ¼" wrench (this nut located on top of spring housing tower), lift off grommet retainer and grommet. Remove nut and lockwasher from shock absorber lower mounting bracket stud (on underside of lower spring seat), lower shock absorber and mounting bracket assembly down and out through hole in spring seat.

►**Installation Note**—When installing rubber grommet assemblies on shock absorber threaded ends, hold end from turning with a ¼" open-end wrench, tighten nut on stem until it bottoms on shoulder. This will provide correct compression of grommets.

COIL SPRING REPLACEMENT: Disconnect stabilizer link at lower control arm bracket, remove shock absorber on side on which spring being removed. Support car on jack stands placed under frame side rails. Place hydraulic jack under lower control arm inner shaft, remove nuts and lockwashers from

CONTINUED ON NEXT PAGE

1949-54 CHEVROLET (C nt.)

control shaft bracket bolts, drive out bolts, lower arm slowly to relieve spring pressure, lift spring out (CAUTION—remove all shims used with old spring). Install spring by reversing this procedure.

►**Spring Installation Caution**—Service replacement springs are checked for height and are furnished with necessary shims wired to the spring.

►***CAUTION—These shims must be installed on top of the spring to insure correct riding height of the car.***

LOWER CONTROL ARM REPLACEMENT: Lower control arm assembly must be removed from the car for replacement of arm, inner shaft, or shaft bushings. Other operations can be performed without removing the assembly.

Removal—Remove wheel and tire assembly, remove front spring (see Coil Spring Replacement), disconnect tie rod from steering arm, remove nut on forward end of lower control arm pivot bolt, unscrew pivot bolt, lift control arm assembly out.

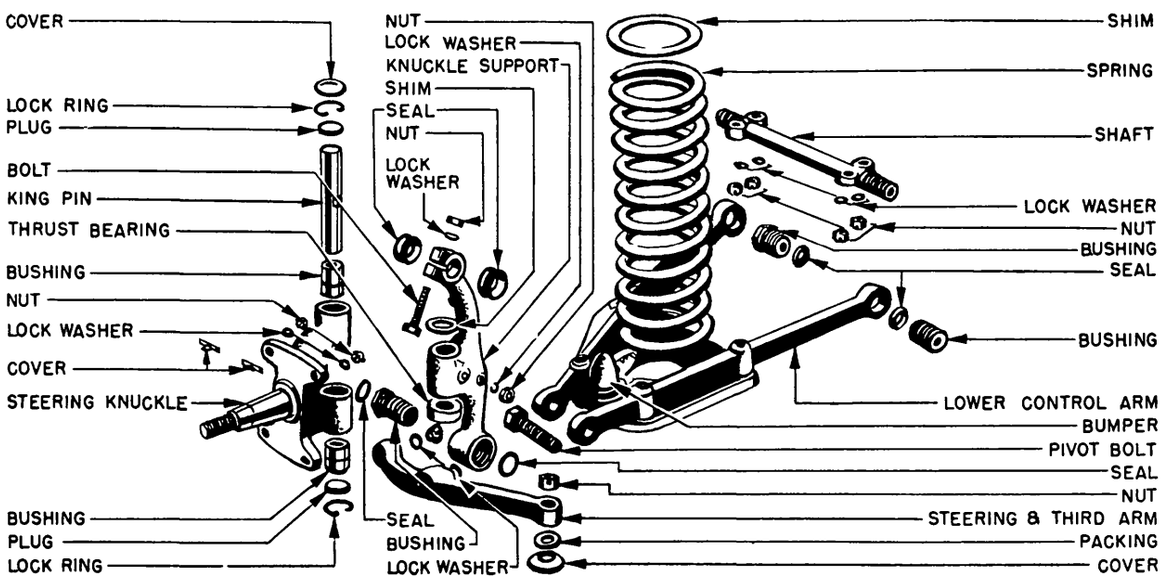
1st. Type Lower Control Shaft & Bushing Installation: Hold control shaft in vise, place new seals on each end of shaft (push seals onto shaft shoulders to permit bushing installation), install bushing locknuts on shaft ends with chamfered side of nuts out toward ends of shaft. Position control arm on shaft, thread bushings on shaft and through control arm, turn locknuts loosely on bushing ends. Install Lower Control Arm Assembly Gauge J-3184 on shaft within arm (tool pin should index with bolt hole in shaft), tighten bushing until inner face of arm contacts end of gauge. Tighten locknut securely, then hold locknut with wrench and tighten bushing to 150-200 ft. lbs. using a torque wrench. Slip seals off shaft shoulders and down into their seats.

Later Type Lower Control Shaft & Bushing Installation: Hold control shaft in vise, place new seals on each end of shaft (push seals up onto shaft shoulders). Position control arm on shaft using a scale to center arm on shaft (CAUTION—Gauge J-3184 cannot be used due to welded re-inforcement plate on inner face of arms). Thread bushings on shaft and into control arm making certain that threads on bushing index with threads in arm and engage properly. Tighten bushings to 85-100 ft. lbs. using a torque wrench. Slip seals down into place.

Lower Pivot Bolt & Bushings: Bushing in lower end of knuckle support should be installed from rear-to-front and tightened to 150-170 ft. lbs. Place new seals over exposed ends of bushing, position control arm so that knuckle support is centered in outer end of arm, start pivot bolt through arm from rear-to-front, thread bolt through knuckle support bushing using care not to disturb centered position of support in control arm, continue to screw pivot bolt in and through opposite eye of control arm until bolt head firmly contacts rear face of arm (NOTE—If bolt threads do not index properly with threads in opposite eye of arm, use "C" clamp to compress ends of arm slightly until threads index and bolt can be turned through arm freely). Tighten pivot bolt to 100-200 ft. lbs., then install locknut on end of bolt and tighten nut to 90-120 ft. lbs. Use wire hook to slip seals down off ends of bushing into their seats.

UPPER CONTROL ARM REPLACEMENT: Control arm should be assembled on control shaft in crossmember tower bracket and checked for free movement throughout entire range before connecting knuckle support.

Removal—Support car on jack stand placed under lower spring seat (to keep spring compressed and lower control arm in place), remove wheel and tire assembly. Take out lubricant fitting in rear bushing at outer end of control arm, unscrew both front and rear bushings from arm, remove seals from pivot pin ends. Take out clamp bolt in upper end of knuckle support, slide pivot pin out (use ¼" Allen wrench in pin recess to assist in removal), swing knuckle support out and free of upper control arm. Unscrew front and rear bushings from control arm at inner control shaft (NOTE—On left side of car, remove sheet metal splash guard over steering gear housing for access to rear bushing), lift control arm off shaft. To remove shaft from frame bracket, use Remover & Replacer Tool J-2958 and pull shaft out toward front of car.



►**Replacement Control Arm Note**—Arms furnished with threads in bushing holes slightly undersize to insure snug bushing fit when new arm installed.

►**Replacement Control Shaft Note**—New shafts are marked by "F" on end to insure correct installation ("F" end toward front of car) and diameter of threads which screw into spring housing tower are oversize to insure correct fit (CAUTION—these threads must be lubricated when installing new shaft to avoid tearing threads). *See "Upper Control Arm Shaft Parts & Installation Change" data for shaft sizes and installation precautions.*

Upper Control Shaft & Bushing Installation: Lubricate threads on new shaft to avoid tearing during installation, see that shaft end marked "F" (larger diameter end) toward front of car, use Remover & Replacer Tool J-2598 to install shaft from front-to-rear of spring housing until rear end projects exactly 1⅛" back of housing (CAUTION—Do not back shaft out which will leave shaft loose in housing—rear end is smaller diameter and threads are tapered). Install new seals on ends of shaft, position control arm on shaft using a scale. Lubricate the bushing inner and outer threads, start both front and rear bushings on shaft and into arm (CAUTION—see that control arm not moved out of position more than necessary to start bushing threads—see Caster Adjustment Caution below), turn bushings in until head seats against arm, then tighten bushings to 30-40 ft. lbs. (CAUTION—this is new specification to prevent stripping of threads and distortion and binding of arms). See that seals seated on their seats, install lubricant fittings in bushings, lubricate arm. Check installation for free movement throughout entire range with rubber bumper removed (arm should fall of own weight).

►**Caster Adjustment Caution**—The thread starting points for control arm and shaft are not controlled and it may be necessary to move arm out of centered position by ½ thread pitch or 3/64" to start bushings in arm. This will require correction by Caster Adjustment after suspension assembly completed.

Upper Pivot Pin & Bushings: Position control arm on upper end of knuckle support, install pivot bolt through arm and knuckle support with Allen wrench hole toward rear of car, center bolt in support, install lock bolt in support and tighten to 30-35 ft. lbs. Place new seal on each end of pivot bolt. Lubricate both inner and outer threads of bushing. Thread front bushing on pivot bolt, center knuckle support in arm, thread bushing into arm (CAUTION

1949-54 CHEVROLET FRONT SUSPENSION

CONTINUED ON NEXT PAGE

1949-54 CHEVROLET (Cont.)

—carefully index threads on bushing and arm and see that support does not move out of centered position when starting threads in arm). Install rear bushing similarly. Screw both bushings in until heads seat against arm, then tighten bushings to 30-40 ft. lbs. (CAUTION—this is new specification to prevent stripping of threads and distortion and binding of arms).

KINGPIN BUSHING REPLACEMENT: ***Not necessary to remove knuckle support from car (bushings are "floating" type).*** New bushings are machined to finished size and do not require reaming.

Removal—Support car with jack under lower spring seat, remove wheel and tire assembly. Remove kingpin lock pin, upper bearing plug cover, upper and lower lock rings, and lubrication fittings. Drive sharp drift punch through lower plug, drive kingpin up until upper plug is forced out, then drive kingpin down and remove from below. Lift off steering knuckle and thrust bearing, remove floating bushings from knuckle support.

Installation—Install new bushings in knuckle support (CAUTION—oil grooves in bushing must line up with lubricant fitting hole in knuckle and bushings must be free in knuckle support and on kingpin). Install thrust bearing between lower yoke of steering knuckle and support with shield on bearing upward, install kingpin from below lining up lockpin slot with hole in support. Check knuckle endplay with a feeler gauge, install steel shim between support and top of steering knuckle if this clearance exceeds .006". Install kingpin lock pin, bearing plugs, lock rings, and bearing plug cover.

SPRINGS: Springs have one end ground flat which should be placed at top with shim (when used) between top of spring and spring seat in cross-member. Lower end is not ground and should be fitted in recess in spring seat on lower control arm.

1949-52 Spring Specifications

Model	Color Mark	Part No.
1949 (All)	Yellow	3694612
1950-52 (Convt.)	Black	3694210
1950-52 (Other Synchro-mesh)	Yellow	3694612
1950-52 (Powerglide)	Black	3694210

1953-54 Spring Specifications

Model	Color Mark	Part No.
Convertible	Black	3703787
Others (Synchro-mesh)	Black	3703788
All-Powerglide	Black	3703787

Spring Height Correction—If spring height too low (riding height less than 15⅜"), install not more than two 599810 Shims (1/16" thick) on top of spring.

►*CAUTION*—If more than two shims required to secure correct riding height, replace spring (additional shims will cause spring coils to bottom before rubber bumper on lower control arm stops arm.

►*REPLACEMENT SPRING CAUTION*—Shims furnished with new springs (wired to spring) must be installed with the spring (riding height will not be correct if shims omitted).

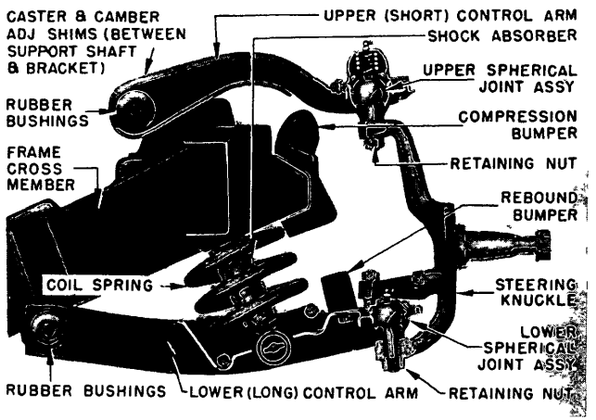
1955 CHEVROLET

Chevrolet Passenger Cars (1955)

DESCRIPTION: Front suspension utilizes short and long arms with spherical type joints connecting control arms and steering knuckles. Coil springs and direct acting shock absorbers are mounted between spring seats on lower control arms and spring pockets in front cross member. Inner ends of upper and lower control arms are mounted on rubber torsion bushings which, in turn, are on forged steel shafts bolted to front cross member (no lubrication required).

ADJUSTMENT: Before making adjustments of front suspension steering geometry check for following: Loose or improperly adjusted steering gear, steering gear housing loose at frame, play or excessive wear in spherical joints, loose tie rod or steering connections, improper front spring heights (see below), underinflated or unbalanced tires, wheel bearings improperly adjusted, shock absorbers not operating properly. *Make adjustments at curb weight.*

Caster & Camber: Caster should be 0°±½°, camber Pos. ½°±½°. Adjustments made by means of shims between upper control arm inner support shaft and support bracket attached to frame side rail. Shims may be changed at either front of shaft or rear of shaft to change caster, or at both points equally to change camber. Addition of shims at front bolt or removal of shims at rear bolt will decrease positive caster. A 1/32" shim difference will change caster ¼°. Adding shims at both front and rear of support shaft will decrease positive camber. A 1/32" shim change will move camber 1/6°. To adjust, loosen upper support shaft-to-bracket bolts, add or remove shims as required, tighten bolts. (*NOTE*—Both caster and camber can be adjusted in one operation).



Steering Axis Inclination: Correct steering axis inclination should be Pos. 3½° plus or minus ½°. The addition of camber and steering axis inclination should be Pos. 4° plus or minus ½°. If not within these limits, knuckle is bent and should be replaced. If new knuckle installed, caster, camber, and toe-in must be readjusted.

Toe-In: 1/8-3/16". Adjust by loosening clamp bolts at each end of each tie rod and turning each tie rod equally to increase or decrease as necessary.

Toe-Out on Turns: Not adjustable. With outside wheel 20°, inside wheel should be 22½° plus or minus 2°. If not within these limits, replace steering arm on wheel side that does not come within limits.

Coil Spring Height: Not adjustable. To check, position car on smooth, level floor. Bounce and rock car several times and allow it to settle to normal height. Measure distance from floor to center of front inner pivot of lower control arm. Record this measurement. Measure distance from floor to lower face of lower steering knuckle boss for spherical joint on same side of vehicle. Record this measurement. Difference between these two measurements should be 2½-3", with vehicle at curb weight. Measure opposite side of vehicle in same manner. It is essential that the two differences be close. To correct height, springs must be replaced. *NOTE*—These springs do not have flat ends and shims should not be used.

FRONT SHOCK ABSORBER REPLACEMENT: With ¼° open end wrench, hold upper stem from turning and remove upper stem retaining nut, grommet retainer and grommet. Remove two bolts retaining lower shock absorber pivot to lower control arm and pull absorber assembly and mounting out at bottom of spring housing. Inspect rubber grommets and, if necessary, replace. To install, place rubber grommet retainer and grommet on upper stem of shock absorber and install shock absorber up through lower control arm and spring housing. Index upper stud through mounting hole in top of spring housing. Install retainer nut to upper shock absorber stem and holding stem with ¼" wrench, tighten nut until it bottoms on shoulder of stem. Tighten to 4-6 ft. lbs. torque and stake in place. Install pivot bolts through lower pivot to lower control arm and tighten securely.

1955 CHEVROLET FRONT SUSPENSION

FRONT SPRING REPLACEMENT: Remove front shock absorber on side spring to be replaced (see above). Raise front end of car off floor and place stand jacks under frame side rails. Lower car on jacks. Remove tire and wheel assembly (*NOTE*—To avoid damage to spherical joints during spring operations). Remove four lower control arm cross shaft bushing bolts. Install Spring Compressor J-5817 through shock absorber mounting hole in front cross member and through spring. Install plate, thrust washer and nut and tighten to slightly compress spring. Remove lower spherical joint cotter pin and nut. Loosen stud by hammering on side of steering knuckle joint boss, backing up steering knuckle with heavy hammer. Remove upper spherical joint stud from knuckle in similar manner, and hang drum and knuckle assembly without loading brake hose. Remove four lower control arm inner shaft-to-cross member nuts and bolts. Unscrew spring compressor nut and remove spring. To install, reverse removal procedure. Rotate spring to make certain it fits helical seats in both cross member and lower control arm.

LOWER CONTROL ARM SPHERICAL JOINT, CROSS

CONTINUED ON NEXT PAGE

1955 CHEVROLET (C nt.)

SHAFT OR BUSHINGS REPLACEMENT: Remove lower control arm (See Front Spring Removal above).

Sph rical Joint R placement: Chisel or drill heads of rivets retaining spherical joint to control arm and drive out rivets Discard spherical joint and seal Install new joint with flange against underside of control arm and retain joint in place with special bolts and nuts supplied with new joint. *CAUTION*–Use only alloy bolts supplied for this operation

Cr ss Shaft r Bushing R placement: Remove bolt, lock lockwasher and collar from each end of cross shaft Install three-piece spacer of J-5888 Bushing Remover and Installer in control arm. Thread a 7/16"-20 capscrew (furnished with J-5888) to bottom of threads in one end of cross-shaft. Support control arm in an arbor press, on support detail of Tool J-5888. (*CAUTION*–Be sure bushing flange does not contact support). Press on capscrew until bushing is free of control arm. Discard bushing. Remove capscrew, insert capscrew in other end of shaft and repeat above operation. To install, coat outside sleeve of bushing sparingly with a lubricant (*CAUTION*–Avoid getting lubricant on rubber bushing). With cross-shaft in control arm and three-piece spacer in place, place control arm on support Hand start bushing into control arm and over end of cross-shaft (*CAUTION*–End of shaft with greatest distance from end of shaft to bolt holes should be toward front of control arm). Install collar of Tool J-5888 over bushing. Be sure three-piece spacer is not over-lapping bushing holes in control arm Press bushing into control arm until flange contacts control arm. Invert arm in press, and repeat above operation on other bushing. After installation, cross-shaft should be able to be rotated by hand. Install collar, lockwasher, and capscrew in each end of cross-shaft but do not tighten.

L w r C ntr l Arm Installation: See "Front Spring - Installation" above. Tighten bushing collar bolts to 45-55 ft. lbs.

UPPER CONTROL ARM SPHERICAL JOINT, CROSS-SHAFT OR BUSHINGS REPLACEMENT: Support vehicle weight at outer end of lower control arm. Remove wheel and tire assembly. Remove cotter pin and nut from upper control arm ball stud. Loosen stud by hammering on side of steering knuckle joint boss, backing up knuckle with heavy hammer. Remove two nuts retaining upper control arm shaft to front crossmember. *Note number of shims at each bolt.* Remove upper control arm from vehicle.

Sph rical J int R plac ment: Same as spherical joint replacement for lower control arm (above), except that flange of joint is installed on topside of upper control arm and a shield is installed around joint on underside of control arm.

Cr ss-Shaft r Bushing R placement: Same as cross-shaft and bushing replacement for lower control arm, except that one-piece spacer instead of three-piece spacer of Tool J-5888 used and 3/8"-24 capscrew (furnished with J-5888) instead of 7/16"-20 capscrew.

Upp r C ntr l Arm Installati n: Reverse removal procedure. Tighten bushing collar bolts to 35-40 ft. lbs

1946-55 CHRYSLER, DE SOTO, DODGE, PLYMOUTH

All Models (1946-55)

►CHANGES & CORRECTIONS

►*1952 FRONT WHEEL SHIMMY CORRECTION (Power Steering Cars): Upper needle bearing in steering knuckle must be removed and replaced with bushings, as follows.*

Cars With Conventional Brakes–Remove needle bearing assembly in upper boss and install bushing Part No. 1483005 (C51 & C55), Part No 871297 (C52, C53, C54) Install bushing with wide open end of lubrication groove toward welch plug Alteration of bushing not required.

Cars With Disc Brakes–Remove steering knuckles, (*CAUTION*–Do not remove disc brakes as an assembly). Separate housing and remove pressure plate assembly. Press needle bearings from upper boss of knuckles. Install bushing Part No. 1408012. *NOTE*–If bushing Part No. 1408012 not available, use Part No. 871297 and rework by removing 5/32" from end of bushing having open end lubrication groove. Remove 1/8" from opposite end. Do not remove entire 9/32" from one end.

DESCRIPTION: Independent "Parallelogram" type with coil springs. 1955 Models have shock absorbers mounted inside front springs.

CHECKING & ADJUSTMENT: Before adjustments made, check wheel and tire balance and run-out, front wheel bearing adjustment and king pin bushing clearance, steering gear adjustment, and shock absorbers. See that springs and shock absorbers in normal position (grasp bumper and work front end of car up and down several times). Then check following points first:

Front Spring Height: With car on level floor, tires inflated to recommended pressure, measure vertical distance from inner and outer ends of lower control arm to floor (center of control arm pin at outer end, center of grease fitting in control arm pivot bar on inner end). See table below for allowable variations. Make measurements at right and left sides of car and compare. If the measurements differ more than ¼', check each front spring for correct installation at top and bottom If springs are correctly installed and measurements made at left and right sides still differ by more than ¼", insert spacers at top of spring between seat and silencer *If more than two spacers required to make correction for a spring, replace spring.* If measurements taken above for allowable difference as shown in table below are not within limits, check rear end of car for unequal spring heights by measuring from spring plate to frame on each side (front spring height will be affected if rear spring heights differ more than ¾")

►*NOTE*· In the following table a plus (+) sign indicates the inner end of lower arm is higher than outer end and a minus (-) sign indicates that it is lower.

1946-55 CHRYSLER, DE SOTO, DODGE, PLYMOUTH (C nt.)

Tire Inflation (1948): Check and inflate to correct pressure for each type tire (below) before checking front end specifications

All Cars with Std. Tires—28 lbs (except DeSoto & & Dodge long-wheelbase cars with 6.50x16 Tires—30 lbs.)

All Cars with Super Cushion Tires—24 lbs. cold

Tire Inflation (1949-55): Check and inflate tires to 24 lbs. (Cold), 27 lbs. (Warm) on all models before checking front end specifications.

Kingpin Inclination

1946-48 (All Models)	4¾-6°
1949-50 (6 Cyl.)	4¾-6°
1949-50 (8 Cyl.)	6¼-7½°
1951-55 (Exc. Chrysler C53, 59, 66, 67, 70)	5-6½°
1951-55 (Chrysler C53, 59, 66, 70)	6½-8°
1955 (Chrysler C67)	5½°

NOTE—Car weight must be on wheels when checking adjustments.

Caster: *CAUTION—All models not set alike.*

1946-48 (All Models)—0° preferred, Limits Neg. 1° to Pos 1°.

1949-54 (Chrysler & DeSoto)—Neg. 2° preferred, Limits Neg. 1° to Neg 3°.

1949-54 (Plymouth & Dodge)—0° preferred, Limits Neg. 1° to Pos. 1°.

1955 (All Cars)—Neg. 2° to 0° (Neg. 2° preferred with manual steering, 0° preferred with power steering). Left side should be 0° to ¾° greater than right side within these limits.

To Adjust—Caster controlled by distance knuckle support upper pivot pin bushing (eccentric camber adjustment) turned in on upper control arm. See Camber Adjustment.

Camber (1946-50): Pos. ¼° preferred. Limits 0° to Pos. ¾°. See Note.

1951-54—Neg. 3/8° to Pos. 3/8°. See Note.

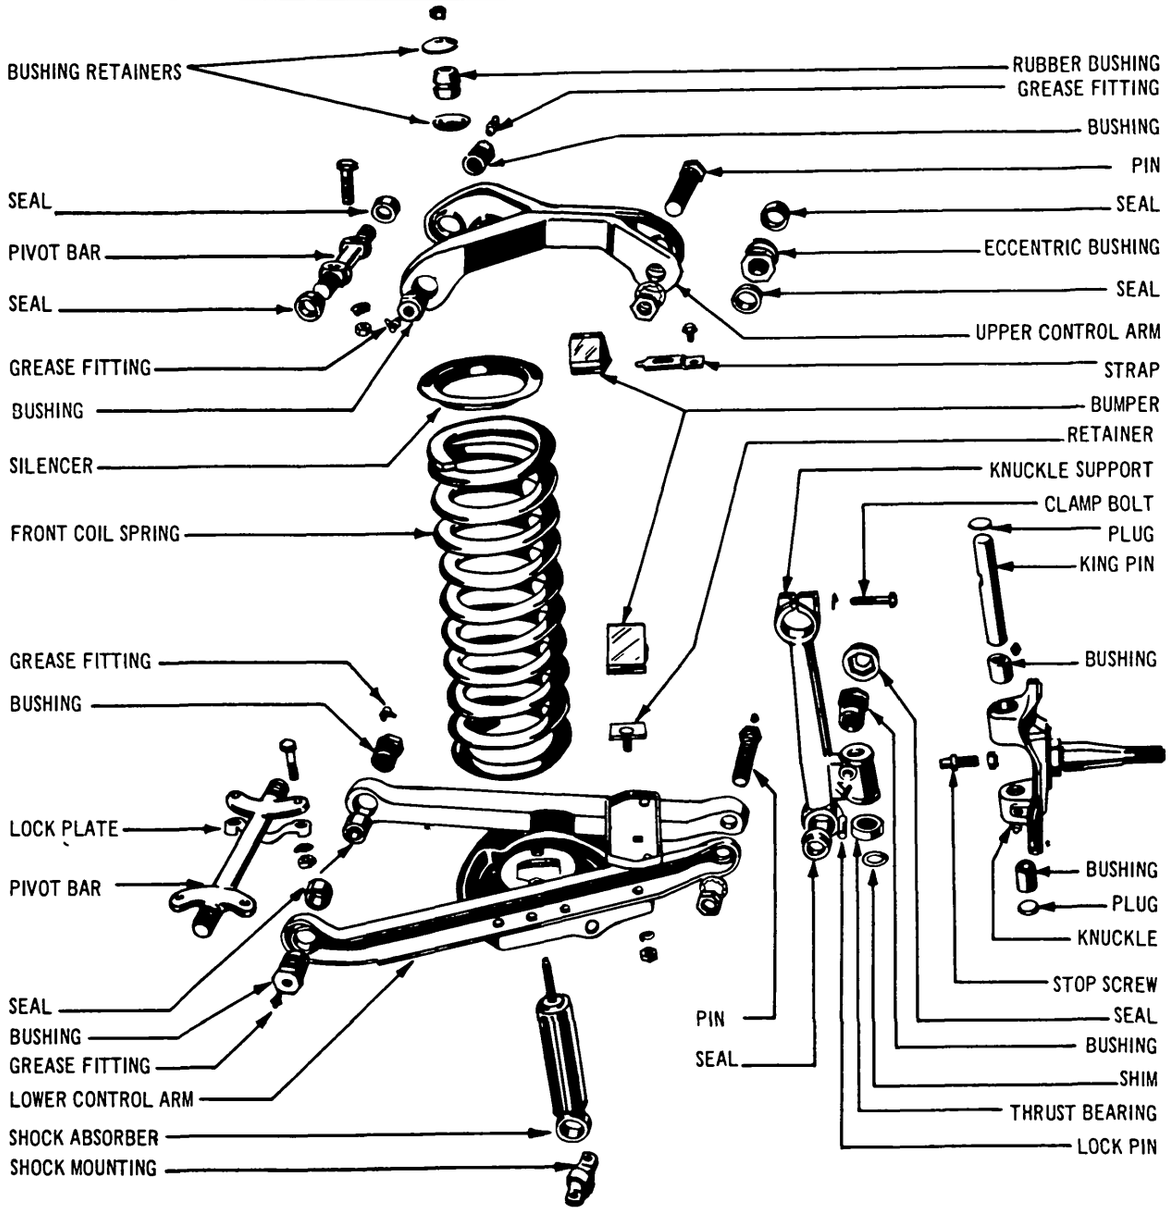
1955 (Chrysler & Plymouth)—Neg 1/8° to Pos. 5/8° (Left side Pos. 1/2°, Right side 0° preferred).

1955 (DeSoto & Dodge)—Pos. 1/4°±3/8° (Left side Pos. 1/2°, Right side 0° preferred).

►*NOTE*· 1949 & Later cars Camber on left side of car should be ¼-½° **greater** than on right side of car

►*TOOL NOTE* Special tool (narrow wrench designed to fit between knuckle support and upper control arm fork so as to engage eccentric bushing) must be used for camber adjustment Tool No C-829 (1 7/16"), C-830 (1½"), or MT-269 (1 5/16") are used with any standard ½" square socket wrench extension

To Adjust—Loosen clampscrew in upper end of knuckle support, turn eccentric bushing in upper end of knuckle support not more than ½ revolution from place where correct caster is secured (bushing eccentric and entire range of adjustment secured in ½ turn) Bushing must not be turned so as to bind on upper control arm



►*CAUTION* Bushing must not be turned so as to bind against either side of upper control arm (keep bushing centered in control arm as nearly as possible)

►*ADDITIONAL RANGE OF ADJUSTMENT* If correct camber cannot be secured by turning eccentric bushing within limits given above, not more than two spacer shims can be installed at top of each front spring Each shim will increase camber approximately ½°

Toe-In: 0" preferred with limits 0" to 1/16" (except 1953 and later Plymouth) 1/8" (1953 and later Plymouth) Check toe-in with wheels turned to straight-ahead position, measure between center of tire treads, hub high, at front and rear of wheels.

T Adjust—Loosen clamp bolts on each tie rod (long rod right side, shot rod left side, or both rods of equal length), turn both tie rods equally. Make certain that ball studs at each end of rod are against same side (to permit angular rotation of rod on ball studs when making turns), and see that clamp bolt on inner (left) end of long tie rod is beneath the rod (to prevent interference on turns)

Toe-Out on Turns: (All Models)—With outer wheel turned

CHRYSLER, DE SOTO, DODGE, PLYMOUTH FRONT SUSPENSION (TYPICAL)

CONTINUED ON NEXT PAGE

1946-55 CHRYSLER, DE SOTO, DODGE, PLYMOUTH (C nt.)

20° inner wheel should be turned 21½°±1° No adjustment provided Check for bent steering arms if incorrect

OVERHAUL: Ste ring Knuckle & Kingpin Bushings—To remove remove wheel and hub assembly Block brake pedal so it cannot be depressed then remove nuts and bolts that fasten brake support to steering knuckle remove steering knuckle arm from steering knuckle Remove brake hose and connections lift off brake support (*CAUTION*—Do not allow brake support and shoe assembly to be supported by flexible brake hose) Remove kingpin locking pin Drive a punch into upper steering knuckle welch plug and pry out of steering knuckle Drive kingpin downward forcing out lower welch plug (*NOTE*—A soft brass drift should be used when driving against head of kingpin) Remove steering knuckle upper bearing or bushing with Tool C 328 Remove steering knuckle lower bushing with same tool if of stationary type (See Note below) Install new lower bushing and line ream with special tool using pilot in place of upper bearing (When upper bushing not used) If upper bushing used install bushing from top making sure slot or identification line is between outer end and grease fitting and line-ream both bushings at same time Install upper bearings from top with trade mark at top and oil hole in bearing lined up with oil hole in steering knuckle Lower bushings should be installed with oil hole in bushing lined up with oil hole in steering knuckle (*NOTE*—On cars equipped with Power Steering and Disc Brakes kingpin bushings should be installed with open end of oil groove leading toward "O" ring seals)

►*FLOATING TYPE BUSHING NOTE* Used at lower end of kingpin on some models These bushings are pre-reamed and should be installed with open end of oil groove upward and with oil hole lined up with oil hole in steering knuckle

Upp r Contr l Arm & Bushings. Install as follows Use new bushings when installing pivot bar and use special spreader tool C-608 to maintain correct control arm spread while bushing being installed Install pivot bar (with seal on each end of bar) in control arm, install spreader tool on inner ends of control arm and bolt pivot bar to tool using two capscrews and nuts (*CAUTION*—Spreader tool has two sets of mounting holes to accommodate all sizes of pivot bars—make certain that correct holes used) Make certain that spreader tool jaws seat firmly against inner faces of control arm ends expand tool until it is just snug against inside of the control arm Start bushings on both ends of the pivot bar lubricate bushings with tapping compound or other suitable lubricants (bushings cut own threads), turn bushings in until shoulder of bushings contact surface of control arm on car With pivot bar correctly installed, only a moderate grip should be required to turn it To correct slight centering error, the pivot bar may be rotated one turn in either direction

Knuckl Supp rt Upper Piv t Pin—Consists of a bolt threaded through both eyes of upper control arm from rear with nut on forward end Seals are installed on pin at each side of eccentric bushing which is threaded on pin within control arm fork (bushing is clamped in upper end of knuckle support by clampscrew) With pin installed, over-all width of control arm fork (from front face of front eye to rear face of rear eye) should be 3 1/8" on all models Eccentric bushing should be centered in fork on all models

Lower Control Arm & Bushings: Control arms and spring seat are riveted assembly Bushings at inner end (frame connection) are self-threading type and new bushings should be used when a new control arm assembly is installed as follows

Control Arm Pivot Bar Bushings—(*NOTE*—Due to relocation of lower control arm pivot bar mounting bolt locations beginning 1955, Tool C-594 cannot be used for centering lower pivot bar, but can be used to maintain set dimension of control arm On 1946-54 models, tool can be used to center the bar) Install dust seals on pivot bar and position bar in control arm Assemble Tool C-594 to bar (*NOTE*—When Tool C-594 used on 1955 models remove guide studs from tool) Lubricate self-threading bushings with light oil, start on both ends of pivot bar, and thread into control arm until shoulders of bushings contact Torque to 165 ft lbs minimum (1946-54), 180 ft lbs minimum (1955) Check pivot bar for free movement *NOTE*—Rotating pivot bar will change setting However, on 1955 models bar can be rotated one turn in either direction to correct a slight centering error For correct centered position of arm as measured from rear face of arm to centerline of rear pivot bar mounting hole, see table below

Knuckle Support Lower Pivot Pin & Bushing—Tighten pin nut to 100 ft lbs minimum Install bushing in knuckle support (head to rear), then position knuckle support so that distance from rear face of support to rear face of support pin boss on rear arm is as shown in table below

Car Model	Arm Centered Position	Support Position
1946-54 (Exc 8 Cyl & 8 Pass)	2 5/32"	15/16"
1946-54 (8 Cyl & 8 Pass)	2 7/32"	1 1/32"
1955 (Exc Chrysler C69,70 8 Pass)	1 11/16'	15/16"
1955 (Chrysler C69 70, All 8 Pass)	1 74"	1 1/32"

FRONT SPRING: Removal—Raise front of car and place stands under frame side members behind suspension arm. Remove shock absorbers (see below) and place jack under lower control arm pivot bar where it is attached to frame crossmember. Raise jack and relieve pressure on pivot bar bolts and remove bolts (place tapered drift in each hole to keep pivot bar lined up until bolts are removed). Lower jack slowly allowing lower control arm to come down, and remove front spring.

Installation—Place spring on end in lower control arm spring seat (flat end up) Lay upper silencer on spring and install lower silencer (if so equipped) Install spring and upper silencer in frame crossmember turn spring until it indexes with lower spring seat and bring lower control arm up to hold it in position (*NOTE*—Some models have lower end coil ground flat and have flat spring seat) *Look up through spring, using a bright light, to see if upper end of spring is positioned correctly Also determin (by feel) if lower end is in position* Raise jack to align pivot bar and frame bolt holes and attach bar to frame Tighten nuts to 60 ft lbs

FRONT SHOCK ABSORBER (1946-54): Removal—Remove nuts from upper and lower mounting studs and remove shock absorber

Installation—Assemble new bushings in shock absorber eyes and install inner bushing retainers Install shock absorber on studs assemble outer bushing retainers and stud nuts Tighten nuts to 60 ft lbs

FRONT SHOCK ABSORBER (1955): Removal—Disconnect end of shock absorber pushrod, and lower mounting. Pull assembly, with lower bushing washer, out through lower control arm. To remove mounting assembly from lower shock absorber eye, place mounting assembly in in Tool C-3413, and using a vise, press out the assembly *NOTE*—The mounting assembly is serviced as a complete unit

Installation—If it is necessary to install a new upper rod mounting bushing, wet the bushing, press it into place and install spacer To install lower mounting assembly in shock absorber eye, position assembly so that mounting holes are at right angles with shock absorber With Tool C-3413, and a vise, press assembly into eye until centered (*CAUTION—To avoid damaging the assembly, always press against steel sleev*). Place lower mounting washer on rod of shock absorber and push shock into position from lower side. Install upper washer and nut, and tighten down to spacer. Install lower mounting screws and tighten to 35 ft. lbs.

►*SPRING IDENTIFICATION NOTE* Part number stamped on all springs (last digit of number indicated by like number of grind marks)

1949-53 FORD PASS. CARS, LINCOLN & MERCURY

Ford Pass. Cars (1949-53)
Lincoln & Cosmopolitan (1949-51) See Note.
Mercury V8 Models (1949-53)

▷*1952-53 LINCOLN NOTE—New "Ball Joint" type front suspension system. See "1952-53 Lincoln" for complete data.*

▷CHANGES, CAUTIONS, CORRECTIONS

▷*1952-53 FORD & MERCURY CAUTION—Suspension system is similar to previous models in basic design, but due to dimensional differences, parts are not interchangeable.*

1953 FORD PARTS REPLACEMENT CAUTION—Front Suspension Lower Arm Assembly Part No. MA-3078A and Front Suspension Lower Arm Bumper Part No. AB-3019B MUST NOT BE INTERCHANGED WITH PREVIOUS MODEL ASSEMBLIES. Lower Arm Bumper Cup Part No. 8A-3028 is discontinued and should not be used with Lower Arm Bumper, Part No. AB-3019B.

▷1952 FORD IDLER ARM STRIKING BUMPER ON LEFT TURN CORRECTION—Check grease fitting installation (nipple must face front of car). Adjust torque of idler arm bushing in steering arm-to-idler rod to 85-100 ft. lbs. Grind off any excess weld build-up where inner and outer frame side rails are welded together.

▷Ford Parts Production Change & New Front End Specifications: Ford cars after March 1, 1949 have new design IDLER ARM BRACKET AND PITMAN ARM which requires new Front End Specifications, (Toe-In) as listed below.

▷*CAUTION—These new design parts must be used together. Under no circumstances should the new and old design parts be used together on the same car.*

New Part Identification—Can be distinguished by differences in dimensions when compared with old parts as follows:

New Idler Arm Bracket No. 8A-3351-C. Supersedes old design bracket 8A-3351-B. New design bracket is longer (5¼" overall changed from 5 1/16"), thinner (5/16" thick changed from 3/8"), and has nut at lower mounting hole (old design had capscrew thread at this mounting hole).

New Pitman Arm No. 8A-3590-B. Supersedes old design arm No. 8A-3590-A. New design arm has greater offset of ½" between flat surfaces of the bolt holes in the ends of the arm (changed from 3/16" offset of old design).

▷New Front End Specifications—New Toe-In setting required for all cars with new design parts as listed above. *See Camber, Caster, Toe-In data following.*

▷1949-51 Ford Front Suspension Noise Correction—Popping noise (when brakes applied) or chucking noise in front end may be caused by incorrect Caster adjustment resulting in caster adjusting bushing striking lower support arm.

▷1949 Ford Riding Height & Car Leveling Correction—Incorrect height or list to one side may be caused by use of unmatched springs or incorrect spring height. Check spring height *(see "Spring Height" & "Springs" following for specifications and correction procedure).*

▷FORD, LINCOLN, MERCURY FRONT SPRING PRODUCTION CHANGES: *See Spring data below.*

▷FORD STABILIZER ASSEMBLY PRODUCTION CHANGE 1950—New design, and can be installed on 1949 cars. *See Front Stabilizer data below.*

DESCRIPTION: Independent, linked parallelogram type with coil springs, and independent shock absorbers.

CHECKING & ADJUSTING: First check wheel bearing adjustment, wheel spindle wear, tire inflation pressure (see data below), wheel run-out and balance (run-out should not exceed ⅛"), steering linkage and steering gear for excessive looseness or play, then place car on level floor and check front end specifications with car at curb weight as follows:

Tire Inflation Pressures (Cold)

Ford—	Size	Ply	Frt.	Rear
Exc. Sta. Wgn. & Sed. Del.	6:00x16	4	28 lbs.	25 lbs.
Exc. Sta. Wgn. & Sed. Del.	6:70x15	4	26 lbs.	23 lbs.
Exc. Sta. Wgn. & Sed. Del.	7:10x15	4	24 lbs.	21 lbs.
Sta. Wgn. & Sed. Del.	7:10x15	4	23 lbs.	26 lbs.
Sta. Wgn. & Sed. Del.	7:10x15	6	25 lbs.	30 lbs.
Mercury—				
Exc. Sta. Wgn. & Conv.	7:10x15	4	26 lbs.	22 lbs.
Station Wagon	7:60x15	4	24 lbs.	24 lbs.
Convertible	7:60x15	4	24 lbs.	22 lbs.

Ford Riding Height (Frame Height at Curb Weight): Before checking front end specifications, check frame height on level floor at curb weight (full tank of fuel but no passenger load) as follows:

Front End Height—Lightly jounce rear end of car several times to allow car to assume natural position. Measure from floor to center of lower support arm pivot pins at inner and outer ends of arm on each side of car. Height at inner end of arm should be ⅛" to 1" greater than height at outer end. If inner end ⅛" greater to ⅛" less than outer end, install shim on spring (see Springs). If inner end more than ⅛" less than outer end, replace spring (see Springs).

Rear End Height—Lightly jounce front end of car several times to allow car to assume natural position. Measure vertical distance from top of axle inner "U" bolt to underside of frame alongside bumper on each side of car (see "Frame Height" in table below). If distance not correct, check for correct spring (Part No. stamped on bottom of shortest leaf under clip plate) and replace spring if it has developed a "set".

Rear Frame Height

Model	Frame Height	Spring No.
3-Pass. Coupe	4 7/8"-6 1/16"	8A-5560-B
5 Pass. Coupe & Sedans	5 7/8"-7 3/8"	8A-5560-D
Convertible	5½"-7"	8A-5560-D
Station Wagon	7 7/8"-7 3/8"	8A-5560-F

Lincoln & Mercury Riding Height: With car at curb weight, measure distance from floor to center of lower control arm pivot pins at inner and outer ends of arm. Height at outer end of arm should be 1" less than at inner end of arm and measurement should be same on both sides of car. If distance not correct, or unequal, correct by shimming or replacing springs (see Springs).

Kingpin Inclination:
(Ford)—5¼° crosswise.
(Lincoln & Mercury)—5° with ¾° camber.

Camber: (Ford) Pos. ⅛° to Pos. ¾° preferred (limits 0° to Pos. 1°) with maximum variation between wheels of ¼°.
(Lincoln & Mercury)—0° to Pos. ¾° with maximum variation between wheels of ¼°.

▷*FORD CAMBER NOTE—Above specifications correct for old and new design parts (see Ford Production Change Note) and supersede earlier specifications.*

Adjustment—Must be made exactly as follows to avoid possibility of binding and noise in front suspension system (as stated in Noise Correction Note above):

1) Back off clampscrew in upper end of spindle support one turn to free the bushing.
2) Install tool No. 3046-N on hexagonal head of bushing in upper end of spindle support, use wrench engaging boss on tool to turn bushing for desired camber.
3) See that support is against shoulder on bushing. When making minimum or maximum camber adjustment, back bushing off slightly to permit free-floating of clampscrew in groove in bushing.
4) Tighten clampscrew to 25-32 ft. lbs.

▷*CAUTION—Clampscrew must not bind on side of groove in bushing (will prevent bushing being held securely and kept from moving in service).*

NOTE—Bushing is eccentric and entire range of adjustment should be secured within ½ turn.

▷*CAUTION—If correct setting not obtained within range of camber bushing movement (½ turn), check all suspension parts for misalignment or wear.*

Caster: (1949-51 Ford Exc. Sta. Wgn.)—Pos. ½° to Neg. 1° with maximum variation between wheels of ½°.

1949-51 Ford Sta. Wgn.—Neg. ¼° preferred (limits Neg. ¼° to Neg. 1¾°) with maximum variation between wheels of ½°.

1949-51 Lincoln & Mercury—Pos. ½° to Neg. 1° with maximum variation between wheels of ½°.

1952-53 Mercury—0° to Neg. 1½°. Must not vary more than ½° between wheels.

▷*FORD CASTER NOTE—Above specifications correct for old & new design parts (see Ford Production Change Note) and supersede earlier specifications.*

Adjustment—Must be made exactly as follows to avoid possibility of binding and noise in front suspension system (as stated in Noise Correction Note above):

1) Back off clampscrew in lower end of spindle support one turn to free the bushing.
2) Install tool No. 3089-N on hexagonal head of bushing in lower end of spindle support, use wrench engaging boss on tool to turn bushing for desired caster.
3) See that support is against shoulder on bushing and that clearance between bushing and arm is at least .045" (if bushing strikes arm when making maximum caster adjustment, back off bushing a minimum of ½ revolution for above clearance).
4) Tighten clampscrew to 25-32 ft. lbs.

▷*CAUTION—Clampscrew must not bind on side of groove in bushing (binding will prevent clampscrew gripping bushing securely to prevent movement of bushing when screw tightened to recommended 25-32 ft. lbs.).*

▷*CAUTION—If correct setting not obtained within range of caster bushing movement (⅛" either way), check all suspension parts for misalignment or wear.*

CONTINUED ON NEXT PAGE

1949-53 FORD PASS. CARS, LINCOLN & MERCURY (Cont.)

►**Toe-In:** CAUTION—Two settings on Ford follow: **Ford (With Old Design Parts—Before Mar. 1, 1949) 1/8" Toe-out to 3/16" Toe-out.**

Ford (With New Design Parts—After Mar. 1, 1949) 1/16" Toe-in to 1/8" Toe-in.

Lincoln & Mercury—3/32" to 5/32" Toe-in.

►***FORD TOE-IN CAUTION—Correct setting must be used for cars with OLD and NEW design parts (as listed in Ford Production Change Note). Settings listed above supersede earlier specifications.***

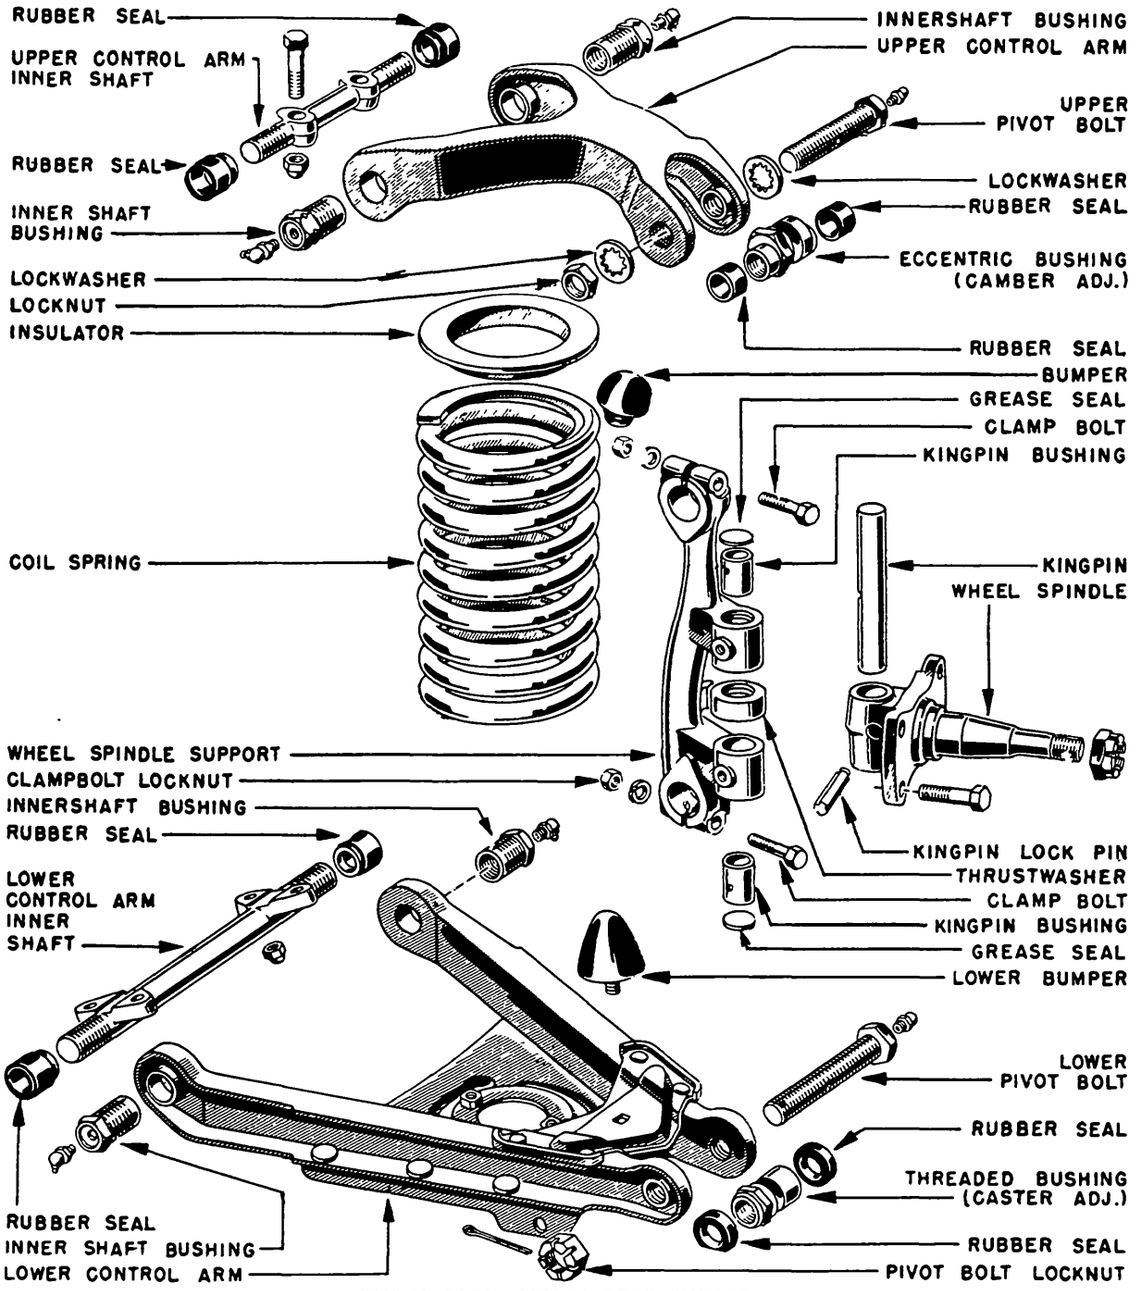
Adjustment—With steering wheel turned to center position and with both front wheels positioned "straight-ahead", loosen clamp bolts on adjusting sleeve at outer end of each tie rod, **turn both adjusting sleeves equally to set toe-in.**

►***FORD ADJUSTMENT NOTE***—If steering wheel spoke not horizontal with wheels "straight-ahead," shorten one tie rod and lengthen opposite rod to align steering wheel and adjust toe-in.

Steering Geometry (Toe-out on Turns): On Lincoln & Mercury, with outer wheel turned exactly 20°, inner wheel should be turned 23½° ± ½°. No adjustment provided. Check suspension system for bent parts if incorrect.

Ford Front Stabilizer: New design clamped directly to each lower control arm at two points (no frame connection).

Removal & Installation—Take out two stabilizer retainer-to-control arm bolts on each arm, remove retainers, lift stabilizer assembly off, slide insulators off stabilizer bar. When assembling stabilzer, use hydraulic brake fluid on insulators when sliding insulators on bar.



►**Installing 1950-51 Stabilizer on 1949 Cars**—Remove and discard old stabilizer. Drill .32" hole (#11 drill) in web of each lower arm assembly at point .78" up from lower face of arm and 7/8" out from outer face of lower spring seat flange. Position stabilizer on lower control arms with **offset upward** (to provide clearance), make certain that projections on clamps engage drilled holes in arms and that clamp bolts are at top. Install outer retainers with bolt hole at the bottom.

SHOCK ABSORBER REPLACEMENT: ***Not necessary to disturb front suspension assembly.*** Remove two capscrews (Ford), nuts on two mounting studs (Lincoln & Mercury) which hold shock absorber mounting plate on underside of spring seat on lower control arm. Remove nut on mounting stud at upper end of shock absorber, lower unit through hole in spring seat.

COIL SPRING REPLACEMENT: Support car on jack under frame. Remove shock absorber (see above). Disconnect stabilizer by removing end clip. Use a jack under the lower control arm inner shaft to hold shaft against cross-member, take out four mounting bolts in shaft. Lower jack slowly until spring tension is relieved, with spring fully extended, lift spring out. Install spring in same manner. See that flat end of spring is up, install insulator on top of spring (all models), and bottom of spring (Lincoln & Mercury only). Make certain that bottom of spring is properly seated in recess in spring seat on lower control arm. See "Springs" (below) for specifications.

LOWER CONTROL ARM REPLACEMENT: Remove coil spring (see above), remove nut on bolt linking control arm to wheel spindle support, unscrew bolt from arm and support bushing. Install arm in same manner. Hold support and bushing assembly centered in control arm while screwing bolt through bushing. Install new rubber seals on bolt (each side of support).

CONTINUED ON NEXT PAGE

1949-51 FORD—1952-53 FORD SIMILAR

1949-53 FORD PASS. CARS, LINCOLN & MERCURY (C nt.)

►**Lincoln & Mercury Lower Support Arm Frame Mounting Bolt Nut Change**—Nuts on bolts mounting inner shaft on frame were MARSDEN type (Part No. 34397-S) on first cars and **should be changed to** HUGLOCK type (Part No. 34447-S) whenever found in service.

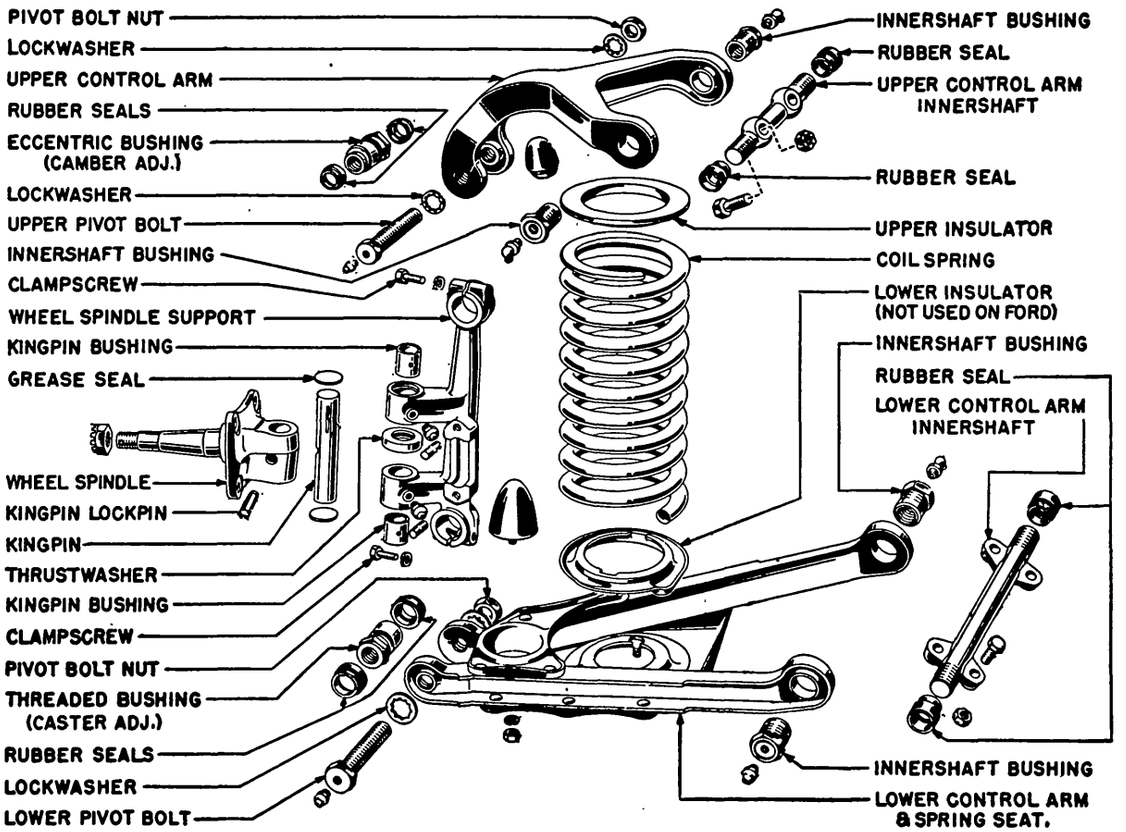
UPPER CONTROL ARM REPLACEMENT: Raise car with a jack under the lower control arm spring seat. Remove wheel. Wire upper end of wheel spindle support to frame (to avoid movement of the support and damage to brake line when arm removed). Remove two capscrews mounting pivot shaft at inner end of control arm on frame. Remove nut on bolt linking upper arm to upper end of wheel spindle support, unscrew bolt from arm and support bushing, lift arm out. Install control arm in same manner. Hold support and bushing assembly centered in control arm while screwing bolt through bushing. Install new rubber seals on bolt (each side of support).

WHEEL SPINDLE SUPPORT REPLACEMENT: Raise car with a jack under the lower control arm spring seat. Remove wheel and brake drum assembly. Take out mounting bolts in backing plate, hang backing plate up on frame (to avoid disconnecting brake line). Drive out kingpin locking pin. Pry out grease seal plug in support above kingpin, drive kingpin down and out of support and wheel spindle (pin will force out lower grease seal plug). Remove nuts on bolts at upper and lower ends of support, unscrew bolts from control arms and support bushings. Lift out support. Bushings can be removed from support by removing clampscrew and pressing bushings out. Install support in same manner.

KINGPIN BUSHING REPLACEMENT: Bushings can be r placed without removing wheel spindle support from the car. Remove wheel spindle (**see Wheel Spindle Support Removal**), **press old bushings out,** press new bushings in and **ream bushings to size** listed below.

Kingpin Bushing—Maximum inside diameter of new bushings: (Ford) .8125-.8135", (Lincoln & Mercury) .9380-.9385". Wear limit inside diameter of old bushings: (Ford) .8185", (Lincoln & Mercury) .9435".
Kingpin—Maximum diameter of new kingpin: (Ford) .8115-.8120", (Lincoln & Mercury) .9365-.9370". Wear limit diameter of old kingpin: (Ford) .8170", (Lincoln & Mercury) .942".
Kingpin Cl aranc in Bushing—New limits (Ford) .0005-.002", (Lincoln & Mercury) .001-.002". Worn limits .009" for all models.

SPRINGS: Springs have upper end ground flat and are marked for identification as follows:
Part No. & Color Marks—Part number marked on outer diameter of flat end of spring coil and spring also paint marked (one or more daubs of special color) as listed in Spring table below.



►**Ford Spring Production Change Mark**—No. 8A-5310-B spring used on first cars has loaded height of 9.2" and is marked by 2-daubs of white paint. Spring used on later cars has loaded height of 9.5" and is marked by 4-daubs of white paint.

►***CAUTION—These springs must not be mixed (use springs with same marking on both sides of car).***
Low & High Limit Spring Marks—Springs are graded in low and high limit groups and marked by a ½" white paint stripe over a minimum of four coils, for mean to low level springs, no white paint stripe for mean to high level springs.

►***SPRING INSTALLATION CAUTION—Springs on both sides of car must be matched (both springs same—Low Limit or High Limit). Car will have visible list toward low limit spring side and camber adjustment will be difficult if unlike springs used.***

Ford Spring Shim Installation (to correct Riding Height): If riding height not correct (see Riding Height data) but within limits which can be corrected by installation of shim, install one shim (Part No. 8A-5355) between top of spring and spring insulator on low side of car.

►***CAUTION—Do not install more than ONE shim on the spring (spring will not be held in place if more than one shim used).***

1952-55 FORD PASS. CARS, LINCOLN, MERCURY

Ford Pass. Cars, Sta Wgn. & Sed. Del. (1954-55)
Lincoln, All Models (1952-55)
Mercury, All Models (1954-55)
Thunderbird (1955)

►CHANGES, CAUTIONS, CORRECTIONS

►*1954 FORD LOWER ARM BUMPER ASSEMBLY INSTALLATION CAUTION* Bumpers are supplied as right-hand (AD-3019-B) and left-hand (AD-3020-B) and are designed to point slightly inboard when correctly installed If right-hand bumper installed on left side or vice versa, bumper will not contact frame on rebound and serious damage to the suspension may result

►*1955 FORD CAR & THUNDERBIRD LOWER ARM MOUNTING BOLT BUSHING INSTALLATION CAUTION* Double-shoulder front suspension lower arm mounting bolt bushing (Part No B4A-3069-D) was released for use on Ford cars and Thunderbird but **was not** used in production Bushing used in production is single-shouldered The front bushing is pressed in from the inside of the lower arm front leg

►*1955 FORD FRONT SPRING SHIM INSTALLATION (When Air Conditioning Unit Installed)* Spring shim and rubber insulator (Part No AD-5355-A) should be installed on top of front springs when air conditioning unit is installed in the field in order to maintain front end and ride height

►*1955 FORD STABILIZER & SHOCK ABSORBER LOCKNUT PRODUCTION CHANGE* To prevent possibility of locknut (45218-S) from coming loose from stabilizer link and shock absorbers, locknut has been eliminated and a lockwasher (34920-S7) has been added Torque nut and lockwasher to 15-25 ft lbs Specification for locknut (45218-S) remains 25-35 ft lbs

►*LUBRICATION CAUTION* DO NOT use any type of lubricant on rubber bushings at inner ends of upper and lower control arms Upper and lower ball joint assemblies are only points requiring lubrication

DESCRIPTION: Front suspension is "Ball-Joint" type similar to design used on Lincoln beginning 1952. With this type design, no Wheel Spindle Support is used and the wheel spindle is connected directly to the upper and lower support arms by Ball-Joint assemblies (ball-joint provided for both wheels turning and up-and-down movement of the suspension) Shock absorbers are direct acting type mounted within the coil springs

CHECKING & ADJUSTMENT: Check wheel bearing adjustment, wheel spindle wear, tire inflation pressure, wheel runout and balance Check steering linkage, and steering gear for excessive looseness or play, then place car on level floor and check front end specifications with car at curb weight

►*ADJUSTMENT CAUTION Due to differences in mounting of upper support arm shaft and location of adjusting shims, all models are not adjusted exactly alike. See Adjustment data following:*

Tire Inflation Pressure For each tire size and model (Cold)

FORD

Model	Tire Size	Lbs. Pressure Front	Rear

C—30 lbs at sustained high speed

Kingpin Inclination: (Ford) 6-7°, (Lincoln) 7°10' with ¾° Camber, (Mercury) 7° with ¾° Camber No Adjustment

Caster: (Ford) 0° to Pos 1°, (Lincoln & Mercury) 0° to Neg. 1½°. Both sides of the car should be equal within ½°

Adjustment (Ford)—Loosen two bolts attaching upper support arm shaft to frame bracket, remove or insert shims at one or the other mounting bolt **This shims located between inner side of shaft and frame bracket.** To INCREASE POSITIVE CASTER, add shim at front bolt or remove shim at rear bolt. To INCREASE NEGATIVE CASTER, remove shim at front bolt or add shim at rear bolt. A 1/16" shim thickness change at either point will change caster ½°. Shims furnished in thicknesses of 1/32" & 1/16". Check Camber. After adjustments completed, tighten shaft bolts to 65-90 ft. lbs.

►*CAUTION—Difference in thickness of shim pack at front and rear bolts must not exceed 1/8".*

Adjustment (Lincoln & Mercury)—Loosen two bolts attaching upper support arm shaft to frame bracket, insert shims at one or the other mounting bolt **This shims located between outer side of shaft and frame bracket.** For POSITIVE CASTER INCREASE, add shim at rear bolt (or remove shim at front bolt), for NEGATIVE CASTER INCREASE, add shim at front bolt (or remove shim at rear bolt) A 1/16" shim thickness change will change caster ½° Shims furnished in thicknesses of 1/32" and 1/8" (also 1/64" and 1/16" for Lincoln) Check Camber After adjustments completed, tighten shaft bolts to 75-90 ft lbs (Lincoln), 70-80 ft lbs (Mercury)

Camber: (Ford) Pos ¼° to Pos 1¼°, (Lincoln & Mercury) 0° to Pos ¾° Both sides of the car should be equal within ¼°

CONTINUED ON NEXT PAGE

1952-55 FORD PASS. CARS, LINCOLN & MERCURY (Cont.)

Adjustm nt (F rd)—Procedure is same as for Caster Adjustment above **xc pt** that shims should be added or removed equally at **both** front and rear bolts. For POSITIVE CAMBER INCREASE, add shims equally at both bolts; for NEGATIVE CAMBER INCREASE, remove shims equally at both bolts. A 1/16" shim thickness change will change camber ¼°. After adjustment completed, tighten shaft bolts to 65-90 ft. lbs. torque.

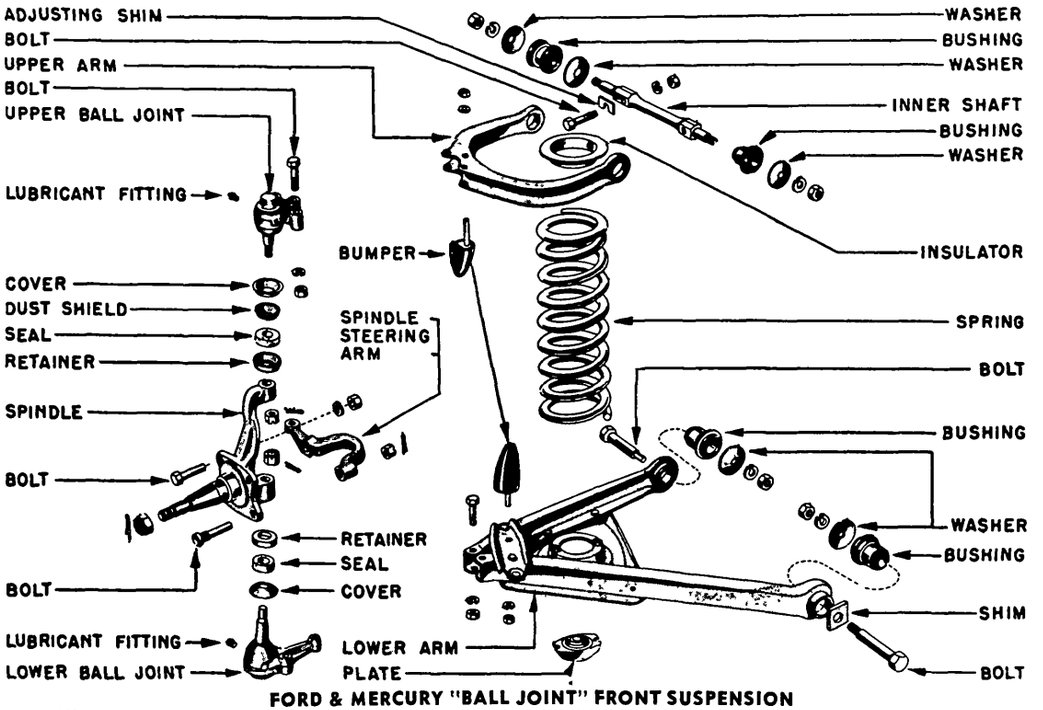
►*CAUTION—Total shim pack thickness at each bolt should not xc d 9/16".*

Adjustm nt (Linc ln & Mercury)—Procedure is same as for Caster Adjustment above **except** that shims should be added or removed equally at **both** front and rear bolts. For POSITIVE CAMBER INCREASE, remove shims equally at both bolts; for NEGATIVE CAMBER INCREASE, add shims equally at both bolts. A 1/16" shim thickness change will change camber ¼°. After adjustment completed, tighten shaft bolts to 75-90 ft. lbs. (Lincoln), 70-80 ft. lbs. (Mercury).

T -ln: (Ford) 1/16-1/8", (Lincoln & Mercury) 3/32"-5/32".

Adjustm nt (All M d ls)—Loosen clamp bolts on adjusting sleeve at outer end of each tie rod, **turn both adjusting sl v s qually** for correct toe-in (turn sleeves in opposite directions).

►*CAUTION—On Pow r Steering cars, run engine while adjusting to -in to insur control valve being properly cent r d in pitman arm nd of steering arm-to-idler arm rod.*



T -Out n Turns: Inner and outer wheel angles are shown below. No adjustment.

	Inner Wheel	Outer Wheel
Lincoln (1952-53)	36°	26°20'
Lincoln (1954-55)	23½°	20°
Mercury (1954)	24°	20°
Mercury (1955)	24°9'	20°

SHOCK ABSORBER REPLACEMENT: Not necessary to disturb front suspension assembly. Remove two nuts on mounting studs which hold shock absorber mounting plate on under side of spring seat on lower control arm. Remove nut on shock absorber stud at upper end of shock absorber, lower shock through hole in spring seat.

Installati n: Reverse removal procedure. Make certain that rubber bushings and washers installed in correct position, tighten shock absorber stud nuts to 20-35 ft. lbs. (Ford), 20-30 ft. lbs. (Lincoln & Mercury). Tighten shock absorber mounting plate-to-lower support arm capscrews to 12-20 ft. lbs. (Ford), 13-18 ft. lbs. (Lincoln & Mercury).

COIL SPRING & LOWER SUSPENSION ARM REPLACEMENT (Rem val): Raise front of car and place support stand under each frame side rail to rear of lower suspension arm. Remove front wheel, hub, and drum as an assembly. Remove shock absorber (above), disconnect stabilizer bar from lower suspension arm. Loosen lower ball-joint to wheel spindle stud nut approximately two turns and loosen ball-joint (see "Ball-Joint Removal" below). Place a jack under lower suspension arm and raise arm until rebound bumper on upper arm is clear of the frame. Remove nut from lower ball-joint stud and lift wheel spindle up and off the stud. Lower jack until spring tension is relieved and spring can be removed. Remove coil spring, rubber insulator and retainer ring (Note location of these parts to insure correct reassembly). To remove lower suspension arm, take out the two bolts attaching arm to frame. Inspect bushings on inner end of each member and replace if necessary.

FORD & MERCURY "BALL JOINT" FRONT SUSPENSION

Bushing Replacement (Lincoln & Mercury)—Position Split Adapter Ring Tool 3069-F on inside of inner end of rear (short) arm and place Tool 3069 to fit into groove of Tool 3069-F. Place Tool 3069-G over the bushing. Press bushing from arm with an arbor press to remove bushing from the front (long) arm, position flange of inner bushing in Tool 3069 and place Tool 3069-G over the bushing. Press bushing from arm. To install bushings, center bushings in arm hole and place bushing flange on Tool 3069-A (Lincoln), 3069-E (Mercury), then place Tool 3069 over arm. Press bushings in place Tool 3069 over the arm Press bushings into place until shoulder ribs of bushing bottom on suspension arm (do not attempt to press bushing beyond edge of shoulder ribs or raised section of outer sleeve as distortion will result). *CAUTION—Under no circumstances should only one bushing be replaced.*

Bushing Installation (Ford)—Use Tool T54P-3044 to install bushings (this tool is composed of a number of various parts and each part is referred to as a "Detail #6" etc.). Position both halves of Detail #12 on inside of inner end of rear (short) arm and place Detail #6 to fit into groove of Detail #12. Place Detail #5 over the bushing and press bushing from arm with an arbor press. To remove bushing from front (long) arm, position flange of inner bushing in Detail #6 and place Detail #5 over bushing and press bushing from arm. To install bushings, center the bushings in the arm hole and place bushing flange on Detail #7, and then place Detail #6 over the arm. Press bushing into place until shoulder ribs of bushing bottom on suspension arm (Do not attempt to press bushing beyond edge of shoulder ribs or raised section of outer sleeve as distortion will result). *CAUTION—Under no circumstances should only one bushing be replaced.*

Installation: Install the lower arm rear leg to frame cross member and tighten attaching nuts to 55-75 ft. lbs. torque. Add enough shims between forward arm and frame to fill the existing space, and tighten nut finger tight. Loosen nut on rear arm and run it up finger tight. With the arm in curb load position (approximately horizontal with outer ends slightly lower than inner) torque the attaching nuts to 55-75 ft. lbs. Place coil spring and upper rubber insulator in position. With a jack under the lower suspension arm, raise arm to compress coil spring. Care must be taken so that both upper and lower ends of spring are properly seated. Guide the spindle boss over ball joint stud. Install nut and torque to 100 ft. lbs., continue to tighten until cotter pin hole is lined up. install cotter pin. Remove jack from under suspension arm, and install shock absorber. Secure stabilizer to lower suspension arm with spacer, insulator, washers, and bolt. Install wheel and hub assembly and adjust front wheel alignment.

CONTINUED ON NEXT PAGE

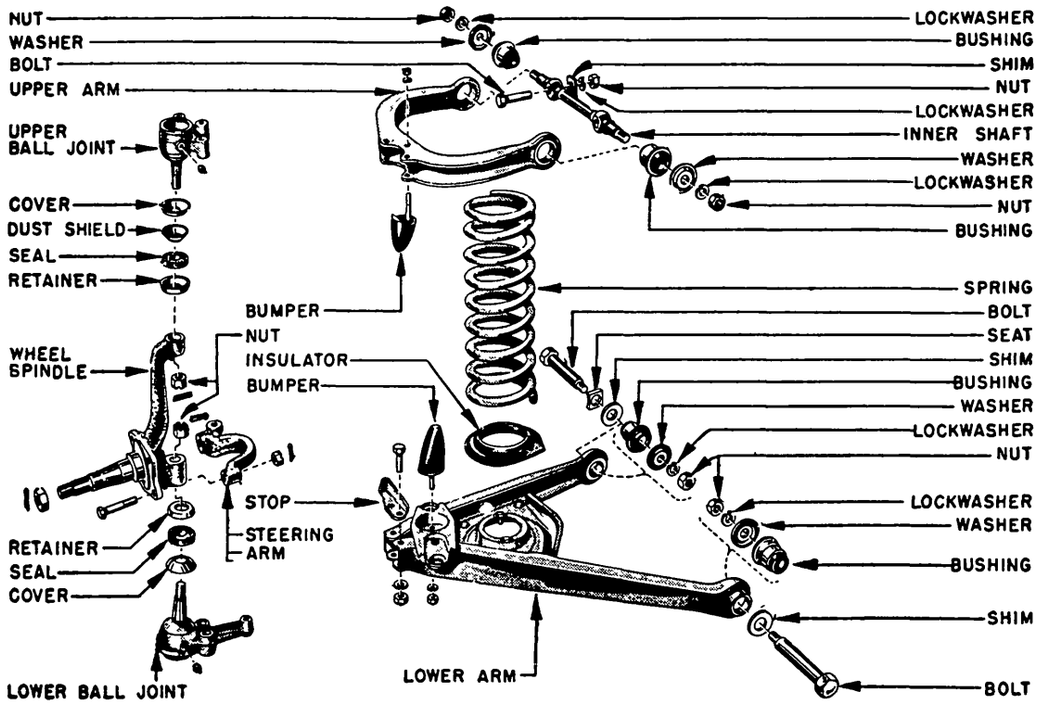
1952-55 FORD PASS. CARS, LINCOLN & MERCURY (Cont.)

BALL-JOINT REMOVAL (Upper & Lower): Ball-joints are furnished as assemblies except for seals and related parts assembled on ball-joint stud. Raise front of car with a jack placed under lower control arm, then place a support under frame side rail to rear of suspension arm. Remove front wheel and remove cotter pin in ball-joint stud (NOTE—If both ball-joints are to be removed, free the lower stud first). Loosen stud hex nut approximately 2 turns and install Tool 3006-A with the screw end resting against lower stud nut. Turn screw of tool and apply sufficient pressure to place ball-joint under tension. Strike the spindle sharply at a point opposite the stud bore to pop it loose. Increase tension and strike again if necessary *(CAUTION—Spindle or tool may be damaged if pressure only is used to free stud).* Repeat this procedure with other stud if it is to be removed. Ball-joint assembly can be removed from suspension arm by taking out the three attaching bolts.

Servicing—Remove retainer, seal, and covers from stud, inspect parts for wear or damage and replace if necessary. If new rubber seals being installed, see that they are pushed down into retainer cup before cup is installed on stud. Reassemble all seal parts in original position.

►*CAUTION—Do not wash ball-joint assemblies with solvent which may remove lubricant.*

Installation—Reverse removal procedure as given above. Tighten to following torques:



Ball-Joint Assembly Mounting Bolts

Car	Upper	Lower
Ford	28-43 ft. lbs.	65-90 ft. lbs.
Lincoln & Mercury	30-40 ft. lbs.	70-90 ft. lbs.

Ball-Joint Mounting Stud Nuts—Tighten stud nuts to minimum torque of 80 ft. lbs. (upper ball-joint), 100 ft. lbs. (lower ball-joint), and then continue to tighten until cotter pin holes line up.

UPPER SUSPENSION ARM REPLACEMENT (Removal): Place jack under lower suspension arm near ball joint mounting and raise lower arm until some of the tension has been removed from the upper bumper. Remove wheel and tire assembly. Wire spindle to frame to avoid damage to brake hose. Remove cotter pin from ball-joint stud and loosen nut approximately two turns. Loosen ball-joint stud (see "Ball-Joint Removal" above), then remove ball-joint stud hex nut. Remove the two bolts securing inner shaft to frame (NOTE—Check the number of shims removed from between shaft and frame (Lincoln & Mercury), or between nut and frame (Ford), at each end of bolt locations). Remove upper suspension arm.

Bushing Replacement (Lincoln & Mercury)—Install Tool 3044-B on the inner shaft and place Tool 3069 over bushing. Press bushing from arm. Remove inner shaft and steel washer. To remove the opposite (double shoulder) bushing, on the rear upper arm, insert Tool 3069-F into flange of arm, then place Tool 3069 over bushing and into recess of Tool 3069-F. Center bushing over Tool 3069-G and press out. (NOTE—Tool 3069-G will shear rubber until steel shell is contacted). To install double shouldered bushing in rear of upper arm, lubricate rubber portion of bushing for easier installation. Position Tool 3069 on inner side of rear arm. Install bushing in hole from outer side of arm, position tool 3068 (Lincoln), 3068-C (Mercury) over bushing. Press bushing into arm to shoulder stop. Install long machined end of inner shaft, with washer on shaft, into bushing. Install bushing on front arm, positioning it over end of shaft and pressing it into place with Tool 3068. With both bushings in place, install washer and nut on each end of shaft and tighten finger tight. Position shaft in suspension arm so that holes are parallel with shaft and tighten nuts to 55-75 ft. lbs. torque. *CAUTION—Under no circumstances should only one bushing be replaced.*

LINCOLN "BALL JOINT" FRONT SUSPENSION

►*FORD TOOL T54P-3044-A (Detail #10) REWORK TO AVOID INTERFERENCE:* If interference between upper suspension arm rod and "Detail#10", correct by grinding a 1/8" radius on bottom inner edge of each half of tool, blending it into the flat portion of tool. A pencil type grinder should be used for this purpose.

Bushing Replacement (Ford)—Remove front bushing first. Install Tool 3044-A Detail #10 (see Note above) on the inner shaft and place Detail #6 over bushing. Press bushing from arm. Remove inner shaft and steel washer. To remove opposite (double shoulder) bushing, on the rear upper arm, install Detail #6 over bushing and center bushing over Detail #9. Press bushing from arm. To install double shouldered bushing in rear of upper arm, install Detail #6 on inner side of rear arm. Install bushing in hole (entering it from outer side of arm), and position Detail #9 over bushing. Press bushing into arm until shoulder stop is reached. Install long machined end of inner shaft, with washer on shaft, into bushing. Install bushing on front arm, positioning it over end of shaft and pressing it into place with Detail #8. With both bushings in place, install washer and nut on each end of shaft and tighten finger tight. Position shaft in suspension arm so that holes are parallel with shaft and tighten nuts to 55-75 ft. lbs. torque. *CAUTION—Under no circumstanc s should only one bushing be replaced.*

Installation: Position the upper suspension arm on frame cross member. Install inner shaft-to-frame bolts and insert the same number of shims that were originally used between shaft and frame cross member (Lincoln & Mercury), between inner shaft attaching nut and frame cross member (Ford). Tighten bolts to 70-90 ft. lbs. torque. Place ball joint stud in spindle and install the the nut. Tighten to 80 ft. lbs. minimum, then continue to tighten until cotter pin holes line up.

HENRY J

All Models (1951-54)

DESCRIPTION: Independent, linked parallelogram type with coil springs, and direct acting shock absorbers mounted within the springs

CHECKING & ADJUSTING: Before checking alignment, make sure that front wheel bearing adjustment is correct, and check spindle wear, tire inflation pressure, wheel runout and balance Check steering linkage and steering gear for excessive wear or looseness, then place car on level floor and check front end alignment with car at curb weight as follows.

Tire Inflation Pressure: 24 lbs. (front), 20 lbs (rear), with tires cold

Front Spring Deflection: Before checking springs make sure front suspension is well lubricated, then bounce front end of car up and down several times Measure at each lower arm from top of arm near outer end, upward to top face of frame side rail. Be sure to measure at identical spots on both sides of vehicle to obtain comparable measurements The two measurements must be the same within 3/8" Weak springs are indicated when the outer end of both control arms are slightly above horizontal with respect to the inner ends when vehicle is at curb weight (no one inside). If this condition exists, replace both springs.

Caster: 0° preferred. (Limits Pos. 1° to Neg 1°).

Adjustment—1/16" or 1/8" shims are installed between front suspension lower arm inner pivot and frame at either the rear or front portion of the inner pivot. Excessive negative caster is corrected by placing a shim under the rear end of pivot Excessive positive caster is corrected by shimming under forward end.

Camber: Pos. ½° preferred. (Limits Pos. ¼° to Pos 1°).

Adjustment—Install or remove shims between the upper support arm inner pivot and the shock absorber support. Installing a shim will decrease camber. Removing shims will increase camber

Kingpin Inclination: 4½° preferred (Limits 4° to 4¾°) Not adjustable.

Toe-In: ¼" preferred. (Limits 3/16" to 1/4").

Adjustment—Shorten or lengthen the tie rods Loosen the two clamps on tie rod adjusting link and turn link to adjust rod length as required. Tighten clamps to lock adjustment

Toe-Out On Turns: With inner wheel turned 20°, outer wheel should be 17½° Not adjustable If not correct, replace steering arms

UPPER CONTROL ARM REPLACEMENT: To remove control arm, raise front of car with a jack under frame side rail until front wheel is off floor Remove front wheel and tire Place another jack or block under lower control arm to hold arm and spring in position while upper arm is being removed Place a block under brake drum, or fasten steering knuckle support to coil spring with a strong wire, to hold support upright when upper control arm is removed. Remove bolts and washers attaching inner pivot to shock absorber support If shims are used between pivot and support, set them aside and be sure and use them in the same location when installing control arm Remove nut and pivot bolt from upper end of steering knuckle support, remove seals and lift off upper control arm. Do not remove bushings from steering knuckle support unless it is worn or loose.

Installation—Fit upper control arm in place so outer end, curving downward, straddles steering knuckle support while inner end fits against shock absorber support. Install same shims, if any were removed, between inner pivot and support to make proper camber adjustment possible Install bolts and lockwashers to attach pivot to shock absorber support Tighten to 70-80 ft lbs torque Fit rubber seal in place between each side of steering knuckle support and control arm. Insert outer pivot bolt through the front side of arm, threading it through steering knuckle support. Install pivot nut and tighten to 165 ft lbs torque. Install lubrication fitting in head of pivot bolt. Remove block from under brake drum or wire holding steering knuckle support upright Install wheel and tire and remove jack. After upper control arm is installed, check and adjust front end alignment.

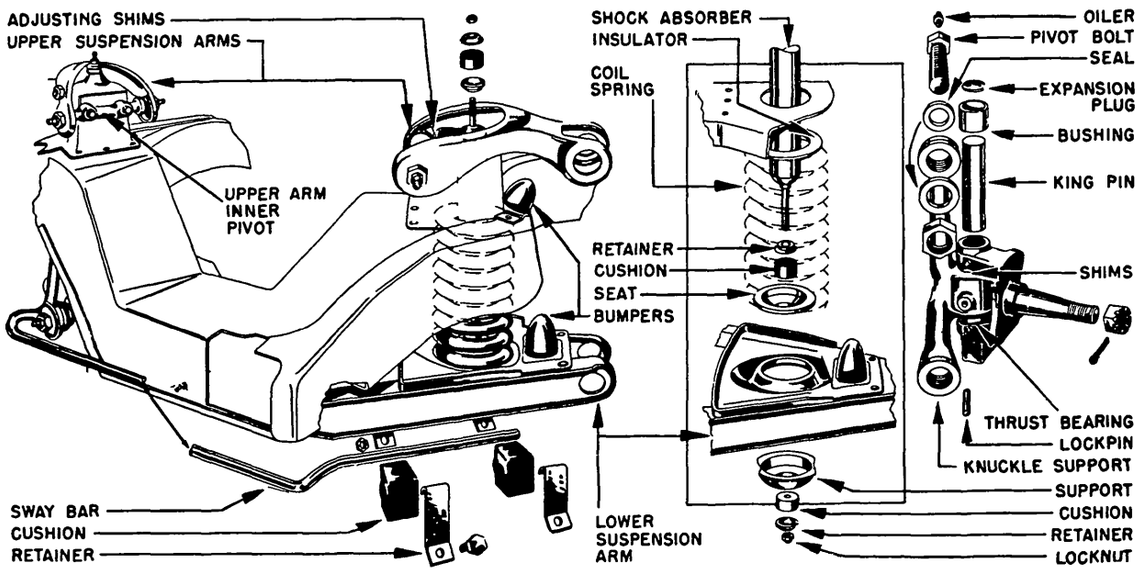
LOWER CONTROL ARM REPLACEMENT: To remove lower control arm, disconnect and remove sway eliminator bar from lower control arms. Raise vehicle with a jack under frame side rail until front wheel off floor. Remove front wheel and tire. Remove shock absorber lower retainer nut, retainer, cushion and cushion seat Place another jack under spring seat on lower control arm Use a wood block between jack and spring seat to prevent slipping Raise jack to support arm firmly when it is detached from front cross-member Remove control arm inner pivot attaching bolts and reinforcements from front cross-member If shims are installed under inner pivot, they should be set aside and used in the same location when installing control arm. Carefully lower jack to relieve front coil spring compression and remove coil spring Remove nut and pivot bolt from lower end of steering knuckle support and remove lower control arm. Do not remove bushing from steering knuckle support unless it is worn or loose.

Installation—Fit lower control arm with spring seat on bottom side of arm in place so outer end straddles lower end of steering knuckle support. Insert a rubber seal between each end of bushing (in the steering knuckle support) and control arm Insert outer pivot through front side of arm, and into bushing in steering knuckle support. Be sure support and bushing are centered between side of arm before pivot is started into bushing Install pivot nut and tighten to 165 ft lbs. torque Install lubrication fitting in pivot bolt Install coil spring with spring and shock absorber attaching parts in proper position (see illustration) Swing lower control arm upward into place on coil spring and shock absorber. Jack up lower control arm until inner pivot seats against front cross-member Install inner pivot reinforcements and attaching bolts and remove jack. Attach lower end of shock absorber to control arm, remove jack under frame side rail and connect sway bar to lower control arm. Check and adjust front end alignment.

STEERING KNUCKLE SUPPORT (Removal): Raise vehicle and remove front wheel and tire, and support the lower control arm to relieve spring pressure Remove wheel hub and brake assembly, brake support plate (brake line does not have to be disconnected), and tie brake support plate to frame Disconnect tie rod end from steering knuckle If

CONTINUED ON NEXT PAGE

HENRY J (C nt.)



steering knuckle and support are to be removed as a unit, remove nuts and pivot bolts connecting ends of support to upper and lower control arms. If steering knuckle is to be removed separately, or is to be disassembled from steering knuckle support, drive out kingpin lockpin from rear side of support. Remove expansion plug from top of steering knuckle by drilling a hole in center of plug and prying plug out with punch. Remove kingpin from knuckle and support by driving it out with a suitable drift against top end. Lower expansion plug will be pushed out ahead of kingpin. Remove steering knuckle, thrust bearing and shims. Remove arm from steering knuckle.

Installation—If steering knuckle and support were both removed, they should be assembled prior to installation on vehicle, as follows: Hold steering knuckle on support. Insert thrust bearing between lower face of support and steering knuckle with open side down. Carefully align bores in knuckle, support, shims and bearing, then drive kingpin into place using a soft drift and hammer. The groove on side of kingpin must align with lockpin hole in support when kingpin is installed. Check fit of steering knuckle on kingpin. A spring scale attached to cotter pin hole in end of wheel spindle should measure not more than 5 lbs. pull to swing knuckle. The vertical movement of knuckle on kingpin should not exceed .002". Add or remove shims between top face of support and steering knuckle as required to maintain vertical clearance of .002". When proper fit is obtained, install kingpin lockpin from front side of support, using a threaded service replacement pin. Install lock washer and nut on threaded end of pin. Install expansion plug in steering knuckle at top end of kingpin and another plug at bottom of kingpin. Expand plugs to fit tightly in knuckle by holding round end of drift against plug and hitting with a hammer. Stake each plug at four places to prevent plug loosening. Install lubrication fitting in steering knuckle. Fit knuckle and support assembly into place on outer ends of control arms. Insert rubber seal between each end of control arm bushings and suspension arms and install pivot bolt through front side of arm and into bushing in support. Install pivot nut and tighten to 165 ft. lbs. torque. Remove jack from under lower control arm, then install steering arm to steering arm. Install brake support plate, wheel hub and brake drum assembly. Install front wheel and tire. Remove jack and check front end alignment.

COIL SPRING REPLACEMENT: See procedure for Lower Control Arm Replacement (above).

►*FRONT SPRING REPLACEMENT NOTE*—Service replacement springs with the same part number which may differ in load rate between limits. Due to this variation, it is possible to match springs by selection for use in service. Replacement springs are marked on the bottom coil with paint—those with a load rate toward the high side of permissable limits are marked with RED, those toward the lower side of permissable limits are marked with WHITE. When using RED and WHITE marked springs together, install the red spring on the left side. Two red or two white springs may be used together provided their load rates differ sufficently to have the front end level after installation.

►*HEAVY DUTY SPRING NOTE*—Heavy duty springs are available for service replacement. These springs are marked by blue paint on center coils, with either red or white marking on the bottom coil to identify load rate. These springs must be used in pairs and heavy duty front shocks must be installed.

HENRY J FRONT SUSPENSION

1946-54 HUDSON (EXCEPT JET MODELS)

All Models (Except Jet) 1946-54

DESCRIPTION: Conventional type with knuckle support pivoted on outer ends of upper and lower support arms. Knuckle support upper pivot is an eccentric bushing (for Camber and Caster adjustments).

CHECKING & ADJUSTMENT: Before checking specifications and making adjustments, always perform the following operations first:
Wheels & Tires—Check wheels and tires for balance and runout, correct if required. Inflate all tires to correct pressure. Check front wheel bearings and adjust if loose. Runout must not exceed 1/16-3/32".
Steering Linkage & Kingpin Looseness—Check kingpin bushings, drag link and connecting rod ends, and steering gear for looseness. Adjust steering gear and replace worn bushings and end joints.
Frame Level and Spring Height—Level car by rocking car sideways (not endwise) several times and allowing it to come to rest. Check spring height at each side of car. If heights not equal within ½", replace or shim low spring (see Springs below)

Kingpin Inclination: Should be equal on both sides of car within ½°.

Kingpin Inclination

1946-47	4° 36' Crosswise
1948-54	3°36' Crosswise

NOTE—Kingpin inclination affected by Camber Adjustment (decreases as Camber increased).

Camber: As listed below. Should be equal within ½° on both sides of car. NOTE—Toe-in setting depends on Camber (check when camber adjusted).

Camber Specification

1946-47	Pos. ¼° to Pos. ¾°
1948-54	Pos. ½° to Pos. 1½°

To Adjust—Adjusted by turning knuckle support upper eccentric pivot pin (Same as Caster Adjustment). See Caster Adjustment below and turn eccentric bushing not more than ½ turn from point where correct caster is secured.

Caster: As listed below. Should be equal within ½° on both sides of car.

Caster Specification

1946-47	0° plus or minus ½°
1948-54	1° (limits) Pos. ½° to 1½°

To Adjust—Loosen clamp bolt in upper end of knuckle support, turn eccentric bushing into support to increase caster, out of support to decrease caster. One complete turn of bushing will change caster ½°. Correct caster of 0° should be secured with center of knuckle support (clamp bolt center) exactly 1 11/32" ahead of face of upper support arm. After correct caster secured, turn bushing not more than ½ turn in either direction to adjust Camber (½ turn will give maximum camber adjustment of plus or minus ½°). Tighten clamp bolt

Toe-In: As listed below. Measure at wheel rim with wheels set straight ahead and intermediate steering arm centered with tool J-1442.

Toe-In Specification

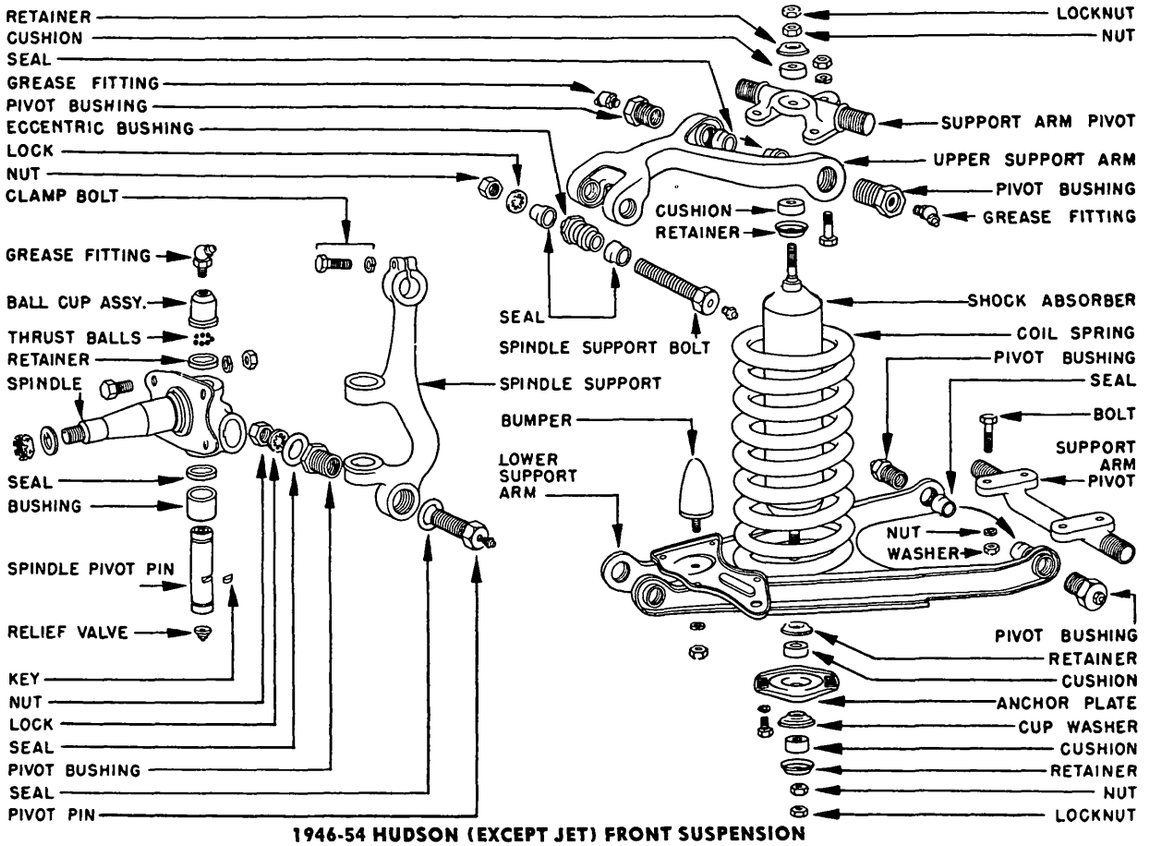
1940-47	0" to 1/16"
1948-51	1/32" (Limits 0" to 1/16")
1952-54	0" to 1/16"

CONTINUED ON NEXT PAGE

1946-54 HUDSON (exc. Jet) (C nt.)

To Adjust—Loosen clamp bolts and turn both tie rods equally. NOTE—Tie rod lengths must be equal **Steering Ge metry:—With inner wheel turned 30°, outer wheel should be turned exactly 25°.** Allowable variation ½°. No adjustment provided.

Lower Support Arm Pivot & Bushing: (Removal)—Raise front wheels clear of floor and place jack stand under inner side of lower support arm. Remove front and rear bushings of lower support arm pivot and remove the four bolts holding lower pivot to front cross-member, then remove pivot.



Installation—Install lower support pivot (NOTE—Lower support arms are identical on right and left sides except that diameter of threaded bosses through which lower support bolt passes, boss facing front of car being threaded .010" larger than ones at rear. A ¼" hole is punched in top plate of left arm assembly for identification). Install coil spring, and lower support arm pivot-to-frame bolts. Use tool J-1052 to maintain exact distance of 11½" between inner faces of support arm and the exact distance of 1½" between inner face of support arm and centerline of the nuts holding pivot to frame cross-member. (NOTE—A .010" oversize lower support arm-to-support bolt bushing is available for wear of steering spindle support. Install shock absorber, mounting plate, rubber bushings, retainers and retainer nuts.

Steering Spindle Support Lower Pivot Pin & Bushing: (Removal)—Raise car with jack under lower support arm and remove cotter key, nut, and washer from lower support arm-to-pivot pin and remove pin and bushing.

Installation—Install bushing in spindle support. Hold steering spindle support squarely between yoke of lower support arm and install lower pivot pin (index the pin so that spindle support is centralized between inner faces of lower support arm). Install washer, nut and cotter pin.

Upper Steering Spindle Support Pivot & Bushing: Raise car so wheels clear floor and remove upper support arm pivot bolt, pivot and bushing. Screw bushing out of upper control arm.

Installation—(NOTE—Upper support arm pivot is self threading). Install tool J-1360 on outer stud of pivot and install pivot so that it is central with the tool. Install spreader tool J-1860 so that the two ends of the tool rest against inner faces of upper support arms and the flange of the support arm fits in the slots machined in ends of spreader tool. Turn hexagon portion of tool until gauge rests against outer surface of arms. This will spread arms 1/16". Start bushings on both ends of pivot. Lubricate them with a lapping compound such as lard oil which will allow bushing to cut their own threads in support arm without scoring. Install upper support arm pivot centering gauge J-1860-2. Thread bushings into support arm until head seats, then tighten to 110 ft. lbs. torque. CAUTION—Upper support arm must have free movement so it will drop of its own weight, plus not more than 5 lbs. pressure from a horizontal position.

1946-54 HUDSON (EXCEPT JET) FRONT SUSPENSION

Eccentric Bushing: (Removal)—Place jack under lower support arm and raise car off floor. Remove eccentric lock screw and washer, cotter pin, nut, and eccentric bushing pivot bolt. Remove eccentric bushing seals and remove bushing from steering spindle support using adjusting wrench KMO-366.

Installation—Install eccentric bushings into steering spindle support with hexagonal head of bushing toward front. Install eccentric bushing lock screw, but do not tighten. Hold steering spindle support in center of upper support arm and install pivot bolt, turn bolt until head seats securely.

SPRINGS: Install with flat end up and silencer on upper end. Shims can be installed on top of low spring to correct minor height differences.

Spring Replacement: Raise car and place jack stands under inner end of lower control arm. Remove wheel. Remove shock absorber upper stud nut and palnut. Remove shock absorber lower mounting nuts and washers. Turn shock absorber ¼ turn and remove through opening. Remove lower support arm pivot-to-frame bolts. Raise car allowing coils to expand, remove spring.

►**Spring Installation Caution—Use High Limit Springs on driver's side of car.**

1946-47 Spring Specifications

Car Model	Spring Color Mark
51, 52 ('46), 171, 172 ('47)	Bronze
53, 54 ('46), 173, 174 ('47)	Orange, Violet, Cream
58 ('46), 178 ('47)	Yellow, White, Green

1948-51 Spring Specifications

Car Model	Color & Part No.
All 6 & 8 (Std.-Light Scale)	Pink—300442
All 6 & 8 (Optl.-Heavy Scale)	Red—301621

1952-54 Spring Specifications

Car Model	Part No.	①Color Mark
All (Right Side)	307193②	White
All (Left Side)	307194②	Red
All (Heavy Duty)	301621	

①—Paint daub across two center coils.
②—Superseding No. 300442 at Car No. 175108.

Spring Identification Note—Springs are paint marked (on two center coils) for identification and have part number stamped on flat end of spring together with Brinell mark and limit marks as follows:

Low Limit Spring Mark—1 Grind Mark or daub of White Paint on lower coil.

High Limit Spring Mark—2 Grind Marks or daub of Red Paint on lower coil.

SHOCK ABSORBER REPLACEMENT: *See "Spring Replacement" above.*

1953-54 HUDSON JET

Jet & Super Jet Models (1953-54)

DESCRIPTION: Independent linked parallelogram type with coil springs and direct acting shock absorbers. Shock absorbers are mounted inside coil springs.

CHECKING & ADJUSTMENT: Before checking alignment and making adjustments, check the front suspension system as follows:

Wheels & Tires—Check wheels and tires for run-out and balance, correct if required. Inflate all tires to correct pressure. Check front wheel bearings and adjust if loose.

Tire Inflation Pressure—5.90 x 15—24 lbs. (front & rear); 6.40 x 16—24 lbs. (front), 22 lbs. (rear).

Steering Linkage & Kingpin—Check all linkage and kingpins for looseness. Check steering gear for looseness. Adjust steering gear and replace worn bushings and end joints.

Frame Level & Spring Height—Rock car sideways several times and allow car to settle. Measure the distance from lower support arm (at a point in center of arm close to the inside, or inner pivot pin side, of the lower support arm bumper), to the bottom of the upper rebound bracket which should be 4 5/32". Measurement between right and left side must not vary more than ½". Replace springs if variation greater.

►***CAUTION—Car must be at curb weight when checking Frame Level & Spring Height.***

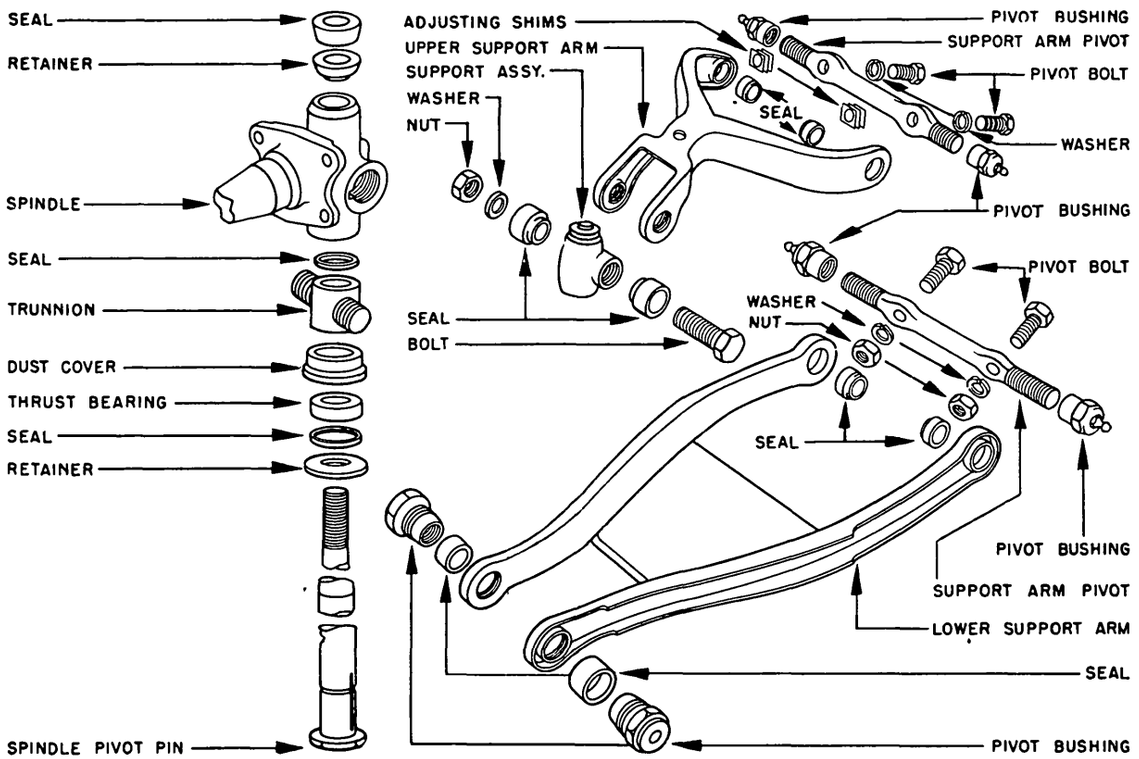
Riding Height—Rear—Measure distance from top of rear axle housing tube to UPPER edge of rear axle bumper. The distance should be 6 1/16" with car at curb weight (no passengers).

Camber: Pos. ¼° to 1¼°. Maximum variation between wheels ½°.

Adjustment—Camber adjustment is provided by shims placed between upper control arm inner pivot and the No. 2 cross-member. Three thicknesses of shims are available (1/32", 1/16", ⅛"). Adding shims will **decrease** positive camber, and removing shims will **increase** positive camber. ***CAUTION—Equal amounts of shims must be installed or removed from both the front and rear bolts of inner pivot.***

Caster: 0° ± ½°. Maximum variation between wheels ½°.

Adjustment—Altering the shim pack between the front or rear pivot attaching bolt changes the caster adjustment. By **adding** shims at the **front** pivot bolt and **removing** shims at the **rear** pivot bolt, **positive caster is decreased. Removing** shims from the **front** pivot attaching bolt and **adding** to the **rear** pivot bolt, **increases positive caster.**



Kingpin Inclination—3°58'. Not adjustable

Toe-In: 0"-1/16". Measured at wheel rim.

Adjustment—Two tie rods. Adjust by loosening clamp bolts and turning tie-rod. Adjust both tie-rods alike.

Toe-Out On Turns: With inner wheel turned 30°, outer wheel should be 25°. Not adjustable, replace steering arms if not correct.

FRONT SUSPENSION REMOVAL (RIGHT OR LEFT): Raise car and place jack stands under inner ends of lower control arms. Remove wheel and tire assembly, and on left side remove fender side shield and battery. Remove shock absorber anchor plate bolts, nuts and washers. Turn anchor plate ¼ turn and push upward to clear spring seat. Disconnect stabilizer connector link from lower spring seat. Remove lower control arm pivot to frame bolts, nuts and washers. ***(CAUTION—Coil springs are under extreme tension and care must be used while removing springs to avoid damage or injury).*** Disconnect outer tie rod end from outer steering arm using tool J-2791. Remove four bolts from brake backing plate and attach brake backing plate under fender to avoid strain on brake hose. Remove upper control arm pivot to frame bolts. Remove front suspension assembly. Wire shim packs together to assure replacement in the same position.

HUDSON JET FRONT SUSPENSION

Installation—Reverse the removal procedure (above) and note the following:

Lower Control Arm—Maintain exact distance of 9½" between inner faces of the control arm while installing bushings. The arm must be centered on the cross-member. The exact distance between the inner face of the control arm and the center line of the bolts holding the pivot to the cross-member should be 1½". These distances must be maintained.

Upper Control Arm—The upper control arm bushing is self-threading in the control arm. In assembling the upper control arm pivot and bushing it is necessary to maintain a proper spread of the pressed steel control arm to insure correct tension on the threads of the pivot after bushings have been installed. Install spreader tool J-3957 with the slotted ends fitting against the inner face of the upper control arm. Turn the hex portion of the spreader tool until the outer surfaces of the control arm measure 7¼" apart. Install the pivot so it is centralized in the control arm. Start the bushings at both ends of pivot. Lubricate them with a tapping compound such as lard oil which will permit bushings to cut their own threads in control arm without scoring. Thread the bushing into control arm and tighten to 110 ft. lbs. torque. (NOTE—The control arm assembly must be free to move from a horizontal position by its own weight plus a pressure no greater than 5 lbs., applied to the arm.) Assemble the upper control arm and pivot to the frame and tighten attaching bolts to 60-70 ft. lbs. torque.

FRONT SPRINGS: Flat end of spring must be installed toward top. Bottom must rest in lower control arm spring seat. Make certain that silencer is in upper spring seat.

Spring Specifications

Car Model	Part No.	Color Mark
Std. (Low Limit	309780	White
Optl. (High Limit)	311046	Red
Heavy Duty	309864	

►**Spring Note**—High & Low Limit springs are available. Spring color mark is located near lower end.

KAISER & FRAZER

Frazer, All Models (1947-51)
Kaiser, All Models (1947-55)
Darrin (1954)

▷INSTALLATION OF 1949 SPRINGS ON 1947-48 CARS: 1949 type higher load rate springs can be installed on these cars. See SPRINGS below.

DESCRIPTION: Independent, linked parallelogram type with coil springs and direct acting shock absorbers.

CHECKING & ADJUSTMENT: Check front wheel bearing adjustment, tire inflation pressure, steering linkage for correct adjustment.

Tire Inflation: Check and inflate tires to following pressures (Cold) before checking front end:
6.50x15 Tires—28 lbs. front & rear.
6.70x15 & 7.10x15—24 lbs. front & rear.

Spring Deflection (Frame Height): Bounce front end of car up and down several times to check for binding in suspension system, then measure from top edge of lower control arm vertically upward to lower face of frame side rail at same point on each side of car. Measurements must be equal within ⅜". If difference more than ⅜", install shim on spring (low one), or replace spring (see Spring data).

Kingpin Inclination: 5½°. Limits 4¾-5¾° crosswise.

Caster: 0° desired, limits Neg. 1° to Pos. 1°.

▷*POWER STEERING NOTE*—Caster on Power Steering equipped cars should be 0° to 1° (½° preferred).

▷*CAUTION*—After adjusting, check control arm for clearance at each side of support. This clearance necessary to prevent binding.

Adjustment—Loosen clamp bolt in upper end of knuckle support, remove lubricant fitting from front bushing at outer end of upper control arm, use wrench KF-25 (Allen wrench) inserted through fitting hole to turn upper pivot pin in complete revolutions only (to avoid disturbing camber adjustment). Check Camber.

Camber: (1947-50)—Pos. ¼° desired; (1951-55)—½° desired. Limits Pos. 0° to ¾°.

Adjustment—Same as for Caster (above) except that eccentric pivot pin should be turned not more than ½ revolution from point where correct caster secured (entire range of adjustment secured in ½ revolution of the pin).

Toe-In: (1947-50)—0" desired. Limits 0" to 1/16". (1951-55)—⅛" desired. Limits 1/16" to ⅛".

Adjustment—Loosen clamp bolts at each end of both tie rods, turn both tie rods equally.

Toe-Out On Turns:	Inner Wheel	Outer Wheel
Right Turn (Power Strg.)	20°	17½°
Left Turn (Power Strg.)	20°	18½°
Right & Left Turn (Others)	20°	17°

SHOCK ABSORBER REPLACEMENT: Raise front of car and disconnect shock absorbers. Compress shock and remove support through spring coils. Remove shock through hole in spring seat. Replace in same manner.

UPPER CONTROL ARM REPLACEMENT: Support car on jacks under frame, remove front wheel. Install jack under spring seat to hold spring and lower arm. Remove lockscrew in upper end of knuckle support. Remove bushings in outer end of upper control arm, use Allen wrench to unscrew eccentric pin from knuckle support. Take out mounting screws in pivot shaft at inner end of control arm,

▷*CAUTION—Do not lose camber adjustment shims under pivot shaft. These shims must be re-installed to maintain correct camber (not used on first cars).*

LOWER CONTROL ARM REPLACEMENT: Support car with jack under frame to rear to suspension unit. Disconnect front sway-eliminator link at spring seat, remove shock absorber (see above). Place jack under lower spring seat to support arm and spring. Take out pivot shaft mounting screws at inner end of arm. Relieve spring tension by lowering jack under spring seat. Disconnect control arm at knuckle support by unscrewing bolt from knuckle support bushing and arm. Lift out arm, spring, spring insulators.

▷*CAUTION—Do not disturb bushing in lower end of knuckle support unless this bushing being replaced.*

SPRINGS: 1949 and later springs have lighter load rate than previous types (can be installed on 1947-48 cars if special instructions given below are followed).

▷Installation of 1949 Springs on 1947-48 Cars—1949 higher load rate springs can be installed on these cars in pairs without other change. If one spring installed, car will appear to sag on opposite side (due to greater stiffness of 1949 spring). This condition can be corrected by installing 1949 type modified upper spring seat and spacer on upper end of original spring.

▷*CAUTION*—Spacer can not be used on spring on 1947-48 cars unless new 1949 type upper spring seat installed (will allow upper end of spring to slip out of position on spring seat).

Spacer Installation (to correct Spring Height): Spacer can be installed between upper end of spring and spring seat of low springs to correct spring deflection on 1949 & later cars only (these cars have modified upper spring seat).

COIL SPRING REPLACEMENT: Disconnect sway bar at lower suspension arm. Raise vehicle with a jack placed under frame side rail until wheel is off floor. Remove wheel and tire. Remove shock absorber retaining nut, retainer, cushion, and cushion seat from under side of lower suspension arm. Hold shock absorber from turning while loosening nut (by inserting pliers through coils and holding shock body). Place another jack under lower spring seat on lower suspension arm. Use a wood block between

CONTINUED ON NEXT PAGE

KAISER FRONT SUSPENSION

KAISER & FRAZER (C nt.)

jack and frame to avoid slipping Raise jack to support arm firmly when it is detached at front cross-member Remove the four nuts and bolts attaching suspension arm inner pivot and the two reinforcements to front cross-member Then carefully lower jack to relieve all compression on front spring. When coil spring is loose, remove spring, upper insulators, shock absorber cushion support, cushion, and cushion retainer

Installation—Fit coil spring insulators into upper and lower spring seats Install front coil spring (flat or finished end into upper spring seat) Install cushion retainer, shock absorber cushion and cushion support over lower end of shock absorber. Move suspension arm up into place, fitting the lower end of shock absorber through spring seat and the ends of the spring into position in spring seats Place jack with wooden block, under lower spring seat on suspension arm Raise jack to compress coil spring until inner pivot seats against underside of front cross-member. Use a drift to line up holes in inner pivot with holes in cross-member and install two reinforcements and four nuts and bolts to attach inner pivot to cross-member. Remove jack from under lower suspension arm. Install cushion seat, shock absorber cushion, cushion retainer and retainer nut on lower end of shock absorber at underside of lower spring seat Install wheel and tire Remove jack from under lower frame side rail Connect sway eliminator bar Check and adjust front end alignment

FRONT SHOCK ABSORBER REPLACEMENT: ***Front shock absorbers can be replaced without removing front springs.*** Raise front end of car with a jack placed at center of front cross-member to relieve tension on spring Remove nut, retainer, cushion, and cushion seat from lower end of shock absorber at underside of lower spring seat Compress shock absorber until stud in lower end clears spring seat and shock lower support Remove the support which rests on top of spring seat by pulling it out through spring coils This will permit withdrawal of the shock absorber through opening in lower seat when retaining nut is removed from top end, (slot in shock stud in upper end permits use of screwdriver to prevent shock turning while removing the nut)

Installation—Install retainer and rubber cushion on upper stud of shock absorber Insert shock through opening in lower spring seat and into place inside front coil spring, with stud with screwdriver slot at top end inserted through hole in shock absorber support Install lower retainer, rubber cushion, and upper retainer and self-locking nut and tighten nut to attach shock solidly to support Fit retainer and rubber cushion onto lower end of shock absorber Compress shock until lower end is raised high enough to permit sliding shock lower support between coils and onto top of lower spring seat Release shock so lower stud fits down through hole in support Install cushion seat, rubber cushion, retainer and self-locking nut on stud from underside of lower spring seat Tighten nut securely.

1950-51 NASH RAMBLER

Nash Rambler (1950-51)

►**FRONT SUSPENSION BRACE PRODUCTION CHANGE:** Beginning with car Serial No. D-66777 (1951) a brace connecting the two lower control arms entered production.

►**FRONT SUSPENSION BRACE INSTALLATION ON CARS BEFORE SERIAL NO. D-66777**—Front Suspension Brace Package, Part No. 3115311 contains all parts necessary for installation of brace on earlier cars.

►**LOWER CONTROL ARM RATTLE CORRECTION**—To prevent lower control arm rattle, a taper shim, Part No. 3111287 must be installed on each side of the lower control arm yoke. The shims are installed with the thick side to the top, between the control arm yoke and the lower control arm. This installation does not affect camber and caster adjustments.

►**CASTER AND CAMBER SHIM LOCATION CHANGE**—Shims have been relocated between the body bracket and spacers. The old location between pivot bar and spacers allowed a loss of torque on pivot bar bolts.

DESCRIPTION: Independent linked parallelogram type with new type coil spring and shock absorber mounting as follows:

►**CONTROL ARM ASSY. INTERCHANGEABILITY CAUTION:** Upper and Lower Control Arm Assemblies are interchangeable from right to left **except that front and rear horizontal arms are not interchangeable** (have 2° twist at inner end) and must be installed in pairs (one stamped "R", one stamped "L").

►**CHECKING GAUGE NOTE:** Flat gauge points provided on knuckle support pin for mounting of Gauge J-1377 to check Caster and Camber.

CHECKING & ADJUSTMENT: First check wheel bearing adjustment, steering gear adjustment, tire inflation pressure, wheel and tire balance and run-out, then place car on level floor and check following specifications:

Kingpin Inclination: 8½° crosswise. No adjustment.

Caster: 1° desired. Limits Pos. ¾° to Pos. 1¼°.
Adjustment—Loosen nuts on **lower** control arm frame mounted pivot bar bolts, add shims to pack on **rear mounting bolt to decrease caster, or front mounting bolt to increase caster.**

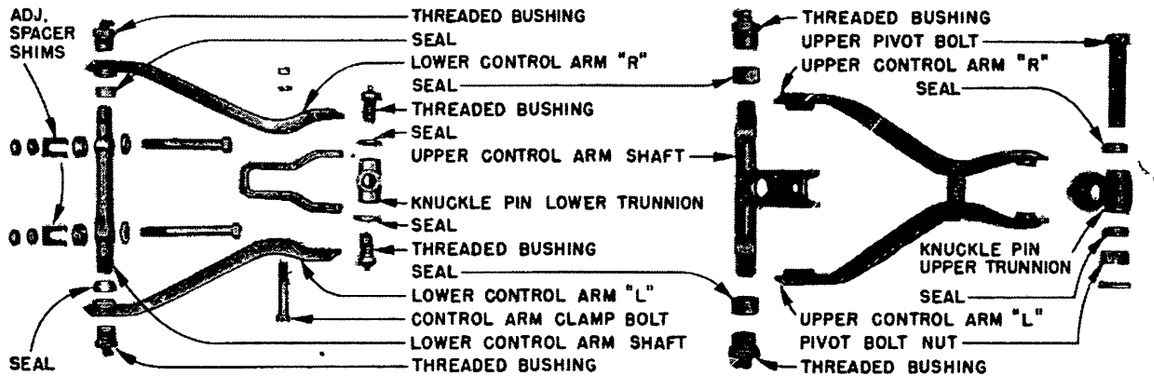
Camber: ½° desired. Limits Pos. ¼° to Pos. ¾°.
Adjustment—Adjust in same manner as Caster (above), except that shims should be **added or removed at both bolts equally** (to avoid disturbing caster). Add shims at both bolts equally to increase camber, remove shims to decrease camber.

Toe-In: ¼" desired. Limits ⅛" to ¼".
Adjustment—Loosen clamp bolts at each end of adjusting tube on outer end of **each tie rod,** turn both adjusting tubes equally.

Toe-Out on Turns: With outer wheel turned 20°, inner wheel should be turned 22½°, plus ½°, minus 0°. Check for bent steering arm if incorrect.

SHOCK ABSORBER REPLACEMENT: ***Not necessary to disturb Front Suspension Assembly.*** Remove bolts in upper and lower control arms which pass through shock absorber eyes, remove shock absorber.

COIL SPRING REPLACEMENT: Use Front Spring Compressor Set J-1608 or KMO-735 (same tools used on "600" suspension springs). Install compressor on spring with car weight on wheels, then raise front end of car so that suspension unit assembly drops down and frees spring, lift spring out.



KNUCKLE SUPPORT PIN ASSEMBLY: Bolt spring seat to upper trunnion first, tightening retaining bolt securely. Screw knuckle support into trunnion until it is tight, **then back knuckle support out one complete turn** to prevent pin bottoming in trunnion when front wheels turned). Screw knuckle support into lower trunnion until clearance of approximately ¼" is provided between upper edge of seal seat on support and trunnion.

Upper Control Arm Trunnion Screw: The upper control arm marked 'R' has a larger pitch diameter thread than the arm marked 'L'. The trunnion screw is provided with a corresponding increase in thread pitch diameter. **At time of installation, the trunnion screw must always be started in the control arm marked 'R', first.**

SPRINGS: Heavier spring used on left side of car.

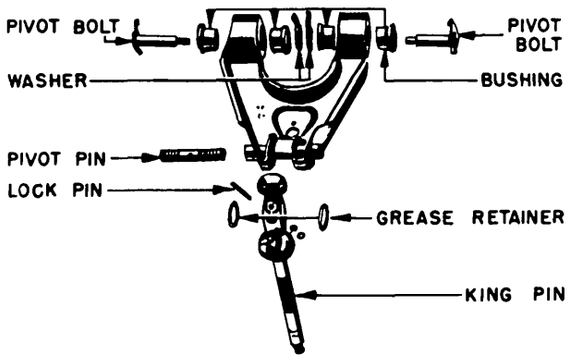
Spring Specifications

	Load	Height
Right (3129503)	755 lbs. ±20 lbs.	10⅜"
Left (3129502)	810 lbs. ±22 lbs.	10⅜"

RAMBLER CONTROL ARM ASSEMBLIES

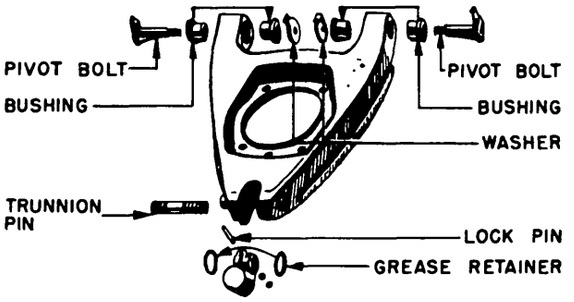
METROPOLITAN (NASH & HUDSON)

Metropolitan (1954-55)



DESCRIPTION: Independent linked parallelogram type with coil spring mounted between upper arm and spring seat in wheelhouse panel. Front shock absorber mounted between lower control arm and bracket on wheelhouse panel.

CHECKING & ADJUSTING: Check wheel bearing adjustment, steering gear adjustment, tire inflation pressure, wheel and tire balance and runout, then with car in a level position, check following specifications.

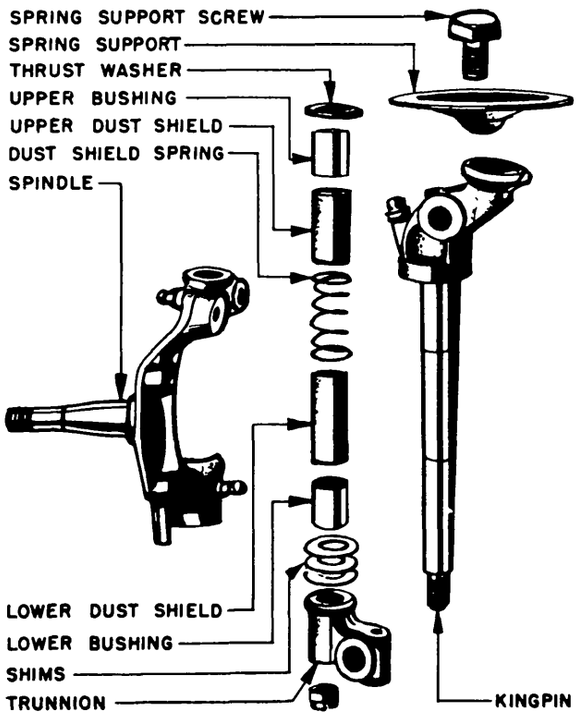


Tir Inflation Pressure: 24 lbs. (front), 22 lbs. (rear), cold.

Kingpin Inclinati n: 6½° Crosswise.
Cast r: Pos. 2° to Pos. 3°. Not adjustable.
Camb r: Pos. ½° to Pos. 1½°. Not adjustable.
T -In: 0-1/16". Adjust center tie rod (between steering gear idler arm and pitman arm).

UPPER & LOWER CONTROL ARMS: Inner ends of control arms are attached to mounting brackets with special bolts and are insulated from mounting brackets with rubber bushings installed in sleeves in control arm. The upper control arm is attached to steering kingpin, and lower control arm is attached to kingpin trunnion at lower end.

UPPER CONTROL ARM ASSEMBLY



LOWER C NTR L ARM ASSEMBLY

Removal: Remove wheel and spring (See "Spring Removal" below), and disconnect tie rod from steering arm, and shock absorber from lower mounting. Remove the two lower control arm mounting bolts noting location of washers, and take out front and rear rubber bushings in mounting bracket. Support wheel spindle and remove nut on lower end of kingpin. Slide lower control arm trunnion off kingpin and remove lower control arm. The upper control arm is removed in the same manner after wheel spindle is removed (See "Kingpin & Wheel Spindle Removal" below).

Installation: Lubricate control arm bracket with Lubriplate and install inner bushings in control arm. Install one side of control arm in bracket and with a large screwdriver, pry between bracket and control arm to compress the bushings and slide control arm into position. Install outer bushings through large holes in bracket and install special pivot bolts, washers, and nuts. Do not tighten pivot bolt nuts until wheel spindle and lower trunnion installed.

LOWER TRUNNION REPLACEMENT (Removal): Remove nut on lower trunnion lockpin and drive pin out of trunnion. Remove grease fitting from end of trunnion pin and screw pin out of trunnion from opposite end.

METR POLITAN FRONT SUSPENSION

Installati n: Reverse the removal procedure, making sure the cutout on trunnion pin is aligned with lockpin hole.

NOTE—If new trunnion pin is a loose fit in the control arm, the control arm should be replaced.

STEERING KINGPIN & SPINDLE REPLACEMENT (R - moval): Remove wheel, spring (See "Spring Removal" below), hub and brake support. Disconnect tie rod from steering arm and shock absorber from lower mounting. Disconnect control arm trunnion from kingpin and slip trunnion off pin. Slip spindle, shims, dust shield assembly, and thrust washer off kingpin. Remove nut from upper pivot pin lockpin and drive lockpin out. Unscrew upper pivot pin and remove kingpin from upper control arm.

Installation: Place a grease retainer on each side of pivot pin bore in kingpin and install kingpin in upper control arm. Install pivot pin and lock in place with lockpin and lockpin nut. Install thrust washer with grooved side upward and install spindle assembly with dust shields and spring on kingpin. Install a sufficient amount of shims between lower shoulder of spindle and trunnion to provide a free turning fit with a minimum amount of endplay. These shims are furnished in .002", .005", .010" thicknesses.

King Pin Bushing Replacement: Use a standard bushing drive to remove and install bushings in spindle. Drive the new bushings in until top of bushing is flush with top of bore in spindle, Make sure lubrication holes in bushing are aligned with holes in spindle. Finish ream bushings with piloted reamers to the following sizes:

Upper Bushing—..6875 to .6880". **Lower Bushing**—6250" to .6255".

COIL SPRING REPLACEMENT (Removal): Raise front of car and support at body side sills. Install **two** front coil spring compressors, Tool KMO-735, enclosing **nine** coils, and compress the spring evenly until it can be removed from car.

►*COIL SPRING COMPRESSOR NOTE:* If a new spring is to be installed, an additional compressor to aid in removing and installing coil spring on tool KMO-735 can be made from two Ambassador lower spring seats drilled through the center with an 11/16" hole, and an 18" long rod threaded 12" on one end and 1" on the other. Install one spring seat on 1" threaded end and secure with a nut. Insert rod through length of spring and install the other drilled spring seat and nut. Spring can then be compressed for removal or installation of tool KMO-735.

Installation: Install spring seat and cushion on each end of spring (cushion with bumper attached is installed at top of spring), and install the entire assembly into position in spring seats in upper control arm and in wheelhousing. CAUTION—Lip of lower spring seat must engage seat in control arm to prevent spring slipping out of position.

Spring Applicati n: (All Models) Part No. 8110335.

1946-51 NASH

"600", All Series 1946-49)
Statesman Series, (1950-51)
Ambassador Series, (1949-51)

►**FRONT SUSPENSION ASSEMBLY UNIT REMOVAL:** If required for overhaul or repair, entire front suspension assembly can be removed as a unit by taking out four bolts which hold the unit on the right and left body sills.

►*CAUTION*—All parts of the rubber insulated mounting bolts must be correctly assembled when installing suspension assembly.

►**STEERING KNUCKLE PIN PRODUCTION CHANGE**—Beginning with Statesman Serial No. K-479398 (Hydra-matic), K-479418 (Synchro-mesh); Ambassador Serial No. R-631514, the steering knuckle pin has been revised to incorporate needle bearings in lower control arm trunnion.

►**1951 AMBASSADOR STEERING ARM PRODUCTION CHANGE**—Effective at Serial No. R-627607, steering arms have been increased in length from 8" to 8 17/32" (measured from center to center on holes). INCORRECT STEERING GEOMETRY WILL RESULT IF CORRECT STEERING ARM IS NOT USED.

DESCRIPTION: Linked parallelogram type with coil springs and independent shock absorbers.

CHECKING & ADJUSTMENT: First check wheel bearing adjustment, steering gear adjustment, tire inflation pressure, (see data below).

Tire Inflation Pressure: 25 lbs. (1946-47), 24 lbs. (1948-51) front and rear.

Kingpin Inclination: 7½° crosswise (1946-48), 8½° crosswise (1949-51). No adjustment.

Caster: Pos. ¼° to Pos. ¾° (1946-48), 0° to Pos. ½° (1949-51).

Adjustment—Loosen nuts at inner ends of upper control arm pivot bar frame mounting bolts, insert "C" washers between frame bracket and pivot bar at front bolt to decrease caster, or at rear bolt to increase caster. Check camber after completing adjustment.

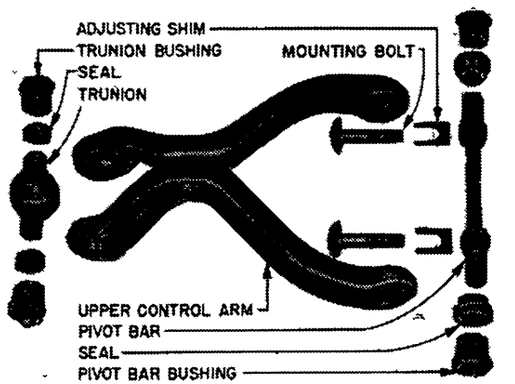
►**Adjusting "C" Washer Note**—These washers furnished 1/16" and 1/8" thick. One 1/16" washer will change caster approximately 1/3°.

Camber: Pos. ¼° to Pos. ¾° (1946-48), 0° desired with limits of Neg. ¼° to Pos. ¼° (1949-51).

NOTE—Machined bosses provided on steering knuckle pin for mounting of J-1377 Caster & Camber Gauge.

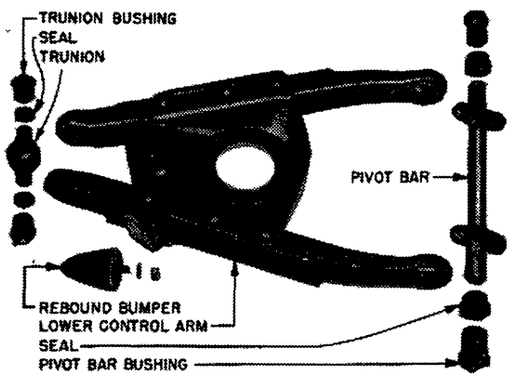
Adjustment—Adjust in same manner as Caster (above) except that washers should be added (to increase Camber) or removed (to decrease Camber) **equally at front and rear pivot bar bolts** to avoid disturbing caster setting.

Toe-In: 1/8 to 3/16".



Adjustment—Loosen clamp bolt at each end of adjusting sleeves on both tie rods, turn adjusting sleeves on **both tie rods equally.**

Steering Geometry (Toe-out on turns): With outer wheel turned 20°, inner wheel should be turned 23¼° (600 '46-48), 23½° (600 '49 & Statesman '50-51), 23° (Amb. '49-51 See Steering Arm Change Note below), plus ½°, minus 0°. Check for bent steering arms if incorrect.



Steering Arm Check—Place straightedge across back of brake support plate, measure from this straightedge to center of steering arm ball stud. Should be 4 3/16" (600 & Statesman), 4 5/16" (Ambassador). Replace arm if incorrect.

►**1951 AMBASSADOR STEERING ARM PRODUCTION CHANGE**—Effective at Serial No. R-627607, steering arms have been increased in length from 8" to 8 17/32" (measured from center to center on holes). INCORRECT STEERING GEOMETRY WILL RESULT IF CORRECT STEERING ARM IS NOT USED.

SHOCK ABSORBER REPLACEMENT: *Not necessary to disturb Front Suspension Assembly.* Disconnect shocks, remove lower shock mounting bracket and remove shock from below.

UPPER CONTROL ARM ASSEMBLY

LOWER CONTROL ARM ASSEMBLY

COIL SPRING REPLACEMENT: Disconnect stabilizer arm link at lower control arm (Amb. only), remove shock absorber (see data above). Install jack under spring seat on lower control arm. Disconnect lower control arm from cross-member at inner control shaft. Raise car by means of a chain hoist until spring pressure relieved. Remove jack under spring seat, lower the lower control arm and lift spring out.

UPPER & LOWER CONTROL ARM REPLACEMENT: Pivot bar at inner end and trunnion at outer end of each arm have threaded bushings and rubber seals which should be installed as follows:

Outer Trunnion: Install new rubber seal on each end of trunnion, center trunnion in outer end of control arm (use Gauge J-2625 to center trunnion in lower control arm), thread bushings in through eyes in control arm and on trunnion ends, use extreme care that trunnion does not move out of centered position, tighten bushings to 125 ft. lbs.

Inner Pivot Bar: Install new rubber seal on each end of pivot bar, center pivot bar in inner end of control arm, thread bushings in through eyes of control arm and on bar ends, use care that bar does not move out of centered position, tighten bushings to 125 ft. lbs.

STEERING KNUCKLE PIN REPLACEMENT: Can be removed without disturbing caster and camber adjustment or other parts of suspension assembly as follows:

Removal: Install spring holding hooks J-2981 to keep front spring compressed (pull car down until hook can be engaged in hole in front suspension extension and in lower control arm). Support front end of car, remove wheel assembly, brake backing plate, and wheel spindle. Remove nut on lower end of knuckle pin, remove large washer, seal, and thrust bearing. Lift knuckle pin up and free of lower control arm, unscrew upper end from upper trunnion.

►***CAUTION—Do not lose spring in upper trunnion above knuckle pin.***

Installation: Use new rubber seals and position knuckle pin as follows:

Upper End—Place seal on pin with open cupped end upward, see that spring in place in trunnion, screw pin in trunnion until distance from top face of seal shoulder on pin to lower face of trunnion is ¼".

►***CAUTION—This ¼" clearance necessary to prevent binding and compression of the grease seal.***

Lower End—Place new seal ring on knuckle pin, insert lower end of pin down through lower trunnion bushing, install thrust bearing, large washer (with new seal ring in groove on rim of washer), and nut. Secure nut with cotter pin.

SPRINGS: ***CAUTION—Springs used on each series have special load rating and are not interchangeable between series.***

►**1951 FRONT SPRING PRODUCTION CHANGE**—Effective with Statesman (serial No. K-503238); Ambassador (serial No. R-649215), spring specifications were changed. *See Late 1951 Specifications below.*

1946-48 Spring Specifications

Car Model	Part No.
"600"	3121238

1949 Spring Specifications

	Free Height	Loaded Height①
"600" 4940	13 1/16"	9" (1640 lbs.)
Amb. 4960	13 3/8"	9" (1830 lbs.)

1950 Spring Specifications
1950 & Early 1951 Spring Specifications

Statesman	13 1/16"	9"②
Ambassador	13 5/8"	9"③

Late 1951 Spring Specifications

Statesman	13⅞"	9¼"④
Ambassador	14¼"	9¼"⑤

①—Indicated loads are plus or minus 40 lbs.
②—Load of 1640 lbs. (RH), 1830 lbs. (LH) ± 40 lbs.
③—Load of 1830 lbs. (RH), 1990 lbs. (LH) ± 45 lbs.
④—Load of 1830 lbs. (RH & LH) ± 45 lbs.
⑤—Load of 1990 lbs. (RH & LH) ± 49 lbs.

Spring Marking Note—Springs are graded and marked by grind mark on end coil as follows:
Low Limit—1 grind mark.
High Limit—2 grind marks.

►***INSTALLATION CAUTION***—**If one Low Limit, and one High Limit spring, installed on same car, install High Limit spring on left (driver's) side of car.**

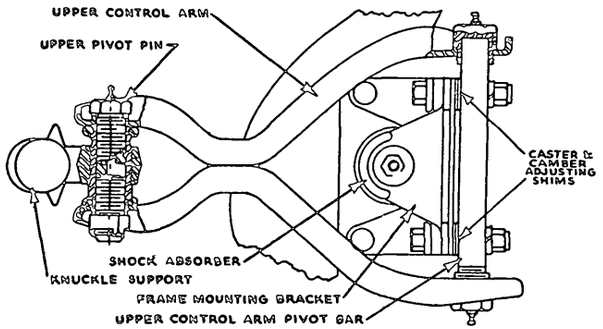
1946-48 NASH AMBASSADOR

Nash Ambassador Six, All Models (1946-48)

DESCRIPTION: Linked parallelogram type with vertical knuckle support linked to short upper control arms.

CHECKING & ADJUSTMENT: Always check following points first before making any adjustments: CAUTION—Always place 2" blocks, Tool J-886, between frame top flange and front suspension upper control arms before jacking up car so as to remove weight from front wheels. Wheels must not be allowed to hang on control arms without these blocks being installed first.

Tire Inflation—Check tires and inflate to pressure of 28 lbs. (1946-47), 24 lbs. (1948).



Wheel & Tire Balance & Runout—Check wheel and tire assemblies for balance. Check front wheels for runout which must not exceed ⅛".

Kingpin Inclination: 4½° crosswise. No adjustment.

Caster: 0° to Negative ½° with car weight on wheels.

Adjustment (1946-48)—Adjusting "C" washers installed on upper control arm pivot bar mounting bolts (between bar and frame bracket). These washers furnished 1/16" thick (equal to 1/3°). To adjust Caster, loosen pivot bar mounting bolts, add shim at front mounting bolt to increase Caster, add shim at rear mounting bolt to decrease Caster, tighten pivot bar bolts. Check Camber.

Camber:—Should be Positive ¼° to Positive ¾° for all models with car weight on wheels and car level

AMBASSADOR UPPER CONTROL ARM

Adjustment (1946-48)—Uses the same "C" washers used for Caster setting (see Caster Adjustment above). To adjust Camber, 'C' washers should be added (to decrease Camber), removed (to increase Camber) equally at both pivot bar mounting bolts. One 1/16" thick 'C' washer will change Camber by 1/3° (normal factory installation consists of two 1/16" washers).

Toe-In: Measure 10" up from floor with wheels set in straight-ahead position.

Toe-In Specifications

1946-48 Amb. Models	1/16—3/16"

Adjustment—Loosen clamp bolts and turn each outer tie rod equally toward front of car to decrease toe-in, toward rear to increase toe-in. Center connecting rod is not adjustable.

Toe-out (Steering Geometry):—With outer wheel turned 20°, inner wheel should be turned exactly as listed below. No adjustment provided. If toe-out incorrect, check for bent steering arms.

Toe-Out Specifications

1946-48 Amb. Models	21½°

SPRINGS: Check spring height on car with special height gauge Tool J-709, which should fit between spring seat on lower control arm and lower face of frame front cross-member. If spring height not correct, replace spring or install ¼" spacer under spring.

1946-47 Spring Specifications

Car Model	Free Length	Part No.
4660, 4760	14 13/16"	①3111316

1948 Spring Specifications

Car Model	Free Length	Part No.
4860	14 13/16"	①3111316

①—Spacer No. 3104309 (⅓" thick) used with this spring.

Spring Identification Note—Springs are graded for load rate and may be identified by grind marks on end coil as follows: 1 Grind Mark—Low Limit, 2 Grind Marks—High Limit. Same type springs should be installed on both sides of car.

1952-55 NASH & HUDSON

Nash (Except Metr politan) 1952-55
Hudson (Except Metropolitan) 1955
Rambler (Hudson & Nash Models) 1952-55

▷CHANGES, CAUTIONS, CORRECTIONS

▷*1953 RAMBLER FRONT SPRING CHANGE (STD & OVERDRIVE TRANS. CARS):* Effective Car Serial No. D-153414 (Kenosha) and DC-12126 (El Segundo) Front Spring No. 3138301 replaces Front Spring Nos. 3129502 (left) and 3129503 (right). Identified by yellow paint 2" wide entire length of spring.

▷*1955 ALL CARS (EXC. RAMBLER) FRONT SUSPENSION CROSSMEMBER INSTALLATION CAUTION:* Reinstallation of the crossmember after removal for service operations requires special attention to proper spacing of the suspension brackets as follows: There should be 19½" between the centers of the front and rear inner crossmember-to-mounting bolt bracket holes to insure maintaining the front wheel alignment.

▷*1955 ALL CARS (EXC. RAMBLER) ECCENTRIC BOLT NUT BOTTOMING ON SHOULDER OF ECCENTRIC BOLT CORRECTION & PARTS PRODUCTION CHANGE:* Eccentric bolt will not tighten sufficiently to prevent eccentric bolt from turning. On early cars install a 5/8" I.D. washer between nut and eccentric washer. At Car Serial V-1511 (Ambassador V8); R-743047 (Ambassador 6 Cyl.); K-635286 (Statesman); Y-1292 (Hornet V8); X-1152 (Hornet 6 Cyl.); W-1200 (Wasp); the counterbore of the eccentric bolt nut has been increased to 3/16".

▷*1955 CASTER & CAMBER ADJUSTMENT (EXC. RAMBLER):* Lower control arm attaching bolts are provided with eccentric washers (one attached to bolt and the other keyed to the threaded end of the bolt). Loosening attaching bolt nut will permit turning the bolt and the eccentrics to provide adjustment for caster and camber.

▷*1955 CASTER & CAMBER ADJUSTMENT (RAMBLER):* "C" type spacers are installed between lower control arm pivot bar and shoulder of mounting stud. Increasing or decreasing the number or thickness of spacers at either front or rear mounting studs permits caster adjustment. Increasing or decreasing equally at both the front and rear will change camber angle for adjustment.

DESCRIPTION: Independent linked parallelogram type with new type coil spring and shock absorber mounting as follows

Coil Springs—Mounted above upper control arm with lower end piloted in spring seat mounted on knuckle support upper trunnion and upper end piloted on spring seat in frame.

Shock Absorber—Upper end mounted on bracket (part of upper control arm pivot bar—Rambler).

▷*NOTE: Front Suspension Systems are similar, but parts are not interchangeable.*

▷*CONTROL ARM ASSEMBLY INTERCHANGEABILITY CAUTION:* Upper Control Arm and Lower Control Arm assemblies *are interchangeable from right t left n Rambler Series only.* Statesman & Ambassador require different control arms for right and left and for front and rear arms.

CHECKING & ADJUSTMENT: Check wheel bearing adjustment, steering gear adjustment, tire inflation pressure, wheel and tire balance and runout, then place car on level floor, check as follows·

Kingpin Inclination: 8½° (Rambler), 6½° (Statesman & Ambassador), 3°36" (Wasp & Hornet). Not adjustable.

Camber: Rambler—Pos. ¼° to Pos. ¾° (½° preferred). Others—Neg. ¼° to Pos. ¼° (0° preferred).

▷*NOTE: Loosen the front suspension brace before adjusting Caster or Camber.*

Adjustment (1952-54)—Add or remove "C" washers equally at both studs, as required, between lower support at both studs, as required between lower support arm pivot bar and frame bracket. Adding washers will increase Camber angle. Removing washers will decrease Camber angle.

▷*CAUTION: "C" Washers of equal thickness must be removed or installed from each end of control arm pivot bar OR CASTER WILL BE CHANGED.*

Adjustment (1955)—Rambler—"C" type spacers are installed between lower control arm pivot bar and shoulder of mounting stud Increase or decrease number of spacers equally at both ends for camber adjustment.

Others—Lower control arms attaching bolts are provided with eccentric washers (one attached to bolt and other keyed to threaded end of the bolt). Loosen-

CONTINUED ON NEXT PAGE

1952-55 NASH & HUDSON (Continued)

ing attaching bolt nut will permit turning the bolt to provide adjustment for caster and camber.

Caster: (Manual Steering, Exc. Rambler)—Pos. ½° preferred (limits 0° to Pos. ½°).

Caster: (Power Steering)—Pos. 1° preferred (limits Pos. ½° to Pos. 1°).

Caster: (Rambler)—Pos. 1° preferred (limits Pos. ¾° to Pos. 1¼°).

Adjustment (1952-54)—Add or remove "C" washers between lower control arm pivot bar and frame mounting bracket as follows: To increase Caster, ADD "C" washer at FRONT end of pivot bar. To decrease Caster, ADD "C" washer at REAR end of pivot bar.

Adjustment (1955)—Rambler—"C" type spacers are installed between lower control arm pivot bar and shoulder of mounting stud. Increasing or decreasing number or thickness of spacers at either front or rear mounting studs permits caster adjustment.

Others—See Caster Adjustment (1955) above.

Toe-In: Rambler—1/8" to 1/4" (1/4" preferred).

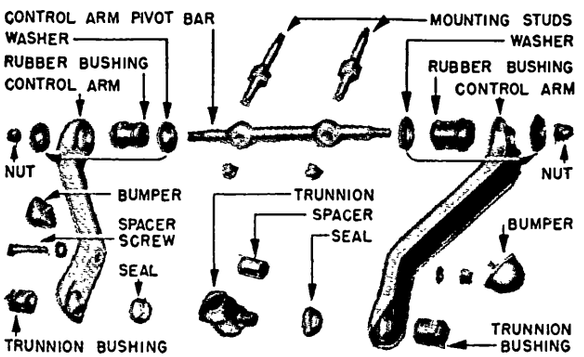
Others—1/16" to 3/16".

Adjustment—Measured at a point 8" above floor with the wheels set in straight-ahead position. Loosen tie rod adjusting tube clamps and turn the adjusting tubes equally in opposite directions.

►*NOTE: Before tightening tie rod clamp bolts, square up the ball joints on their studs.*

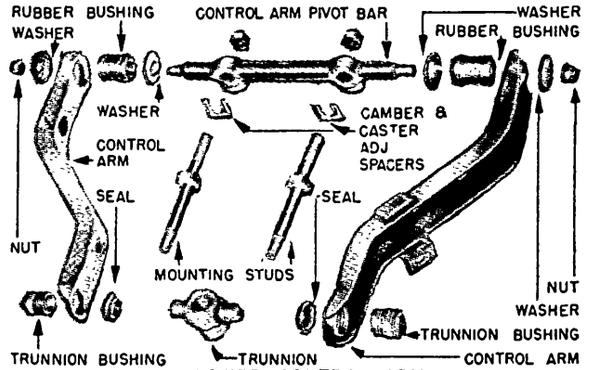
Toe-Out on Turns (1952-54): With outer wheel turned 20°, inner wheel should be 22½° plus ½° minus 0° (Rambler), 23° plus ½° minus 0° (Ambassador). 23½° plus ½° minus 0° (Statesman).

Toe-Out on Turns (1955): With inner wheel turned as indicated in table below, outer wheel should be



Car Model	Inner Wheel	Outer Wheel
Hornet	26°	20°
Wasp	24°	20°
Ambassador	25°	Ⓒ
Statesman	25°	20¾°
Rambler	25°	21½°

Ⓒ—20¼° (exc. V8 Pwr. Str.), 21¾° (V8 Pwr.Strg.).



UPPER & LOWER CONTROL ARMS: Control arms are attached to pivot bars by rubber insulated bushings. Outer end of control arm is attached to trunnions by threaded bushings, except the upper trunnion on Rambler which is attached with a screw and locked in place with a nut and lockwasher.

Removal: Remove the Harris type rubber bushings by driving them straight out of control arm. Do not turn or twist (bushings must be tight press fit).

Installation: Rubber bushings can be installed into the control arms by using two inner bearing cones of suitable size (Statesman or Rambler rear axle rear pinion bearing inner cone is right size) as pressing tools. Place control arm in arbor press and start bushing into flanged side of control arm. Install pivot bar inner washer over bushing and place cups in position (one over washer and the other on the under side of control arm to provide clearance in press). Press bushing into control arm until bushing is ½" from arm.

UPPER CONTROL ARM

LOWER CONTROL ARM

NASH STATESMAN & AMBASSADOR CONTROL ARM ASSYS.

Steering Knuckle Pin Installation (Lower): Screw knuckle pin into lower trunnion until there is approximately ¼" clearance between shoulder on knuckle pin and trunnion.

Steering Knuckle Pin Installation (Upper—Ambassador, Statesman, Wasp, Hornet): Upper control arm trunnion incorporates needle bearings and is retained on knuckle pin by a castellated nut and pin. A thrust bearing installed on knuckle pin between lower side of upper trunnion and a shoulder on knuckle pin absorbs the end thrust of the knuckle pin.

Steering Knuckle Pin Installation (Upper—Rambler): On 1952-54 models bolt spring seat to trunnion prior to installation of knuckle pin into trunnion, then proceed as for lower knuckle pin (above). 1955 models are same as for Ambassador, Statesman, Hornet and Wasp above. *NOTE*—On 1955 models two self-tapping screws must be removed to permit removal of lock pin.

Front Suspension Tightening Specifications: *NOTE*—It is very important that tightness of front suspension system be maintained. The following torque values will insure correct tightness.

	Ft. Lbs.
Pivot Bar Bushing Retaining Nut	50-55
Lower Shock Mounting	90-95
Upper Control Arm Spacer Nut Screw	50-55
Lower Mounting Stud to Sill	75-85
Upper Mounting Stud to Sill	35-45
Upper Pivot Bar to Mounting Stud Nut	75-80
Lower Pivot Bar to Mounting Stud Nut	75-85

COIL SPRING REPLACEMENT: (*NOTE*—Two front coil spring compressors used (KMO-735 for Rambler, J-5224 for Others). Remove two rebound bumpers from upper control arms and raise front end of car to permit spring to extend to its full rebound position. Install upper section of one compressor on highest coil of spring and lower section of other compressor on lowest coil. Lower front end of car to partially compress spring with car weight (Maintain support under front end). Install remaining sections of compressors enclosing the five (Rambler), nine (Others) coils. Raise front of car and remove wheel, hub, and drum as an assembly. Tighten compressors evenly until spring can be removed.

►*CAUTION:* Lip of lower spring seat must engage upper end of knuckle pin to prevent spring slipping off pin.

►*SPRING REMOVAL NOTE: To facilitate installation and removal of spring compressor tools, a spring compressor can be made from two Ambassador Series lower spring retainers and a 5/8" bolt 18" long threaded at both ends. Insert bolt through spring and install spring retainers, then draw spring together by turning nuts on bolt.*

Spring Free Height	
Rambler, 100" W.B. (Early Type Spring)	18"
Rambler, 100" W.B. (Later Spr., Std. & O.D.)	16 7/8"
Rambler, 100" W.B. (Hydra-Matic)	18"
Rambler, 108" W.B. (Std. & O.D.)	18"
Rambler, 108" W.B. (Hydra-Matic)	18 3/8"
Ambassador & Hornet 6	17½-18"
Ambassador & Hornet V8	18¼"
Statesman & Wasp	17 3/16-18 5/8"

►*SPRING HEIGHT NOTE:* Low limit springs identified with one grind mark or white paint, high limit springs identified with one grind mark or white paint, high limit springs with two grind marks or red paint on flat section of end coil.

1946-54 OLDSMOBILE

All Series (1946-54)

DESCRIPTION: Independent linked parallelogram type with double acting shock absorbers integral with upper control arm assembly.

CHECKING & ADJUSTMENT: Check & adjust front wheel bearings, check kingpins for looseness, check shock absorbers and following points:

Tire Inflation—Check tires and inflate to following pressures:

Model	Front	Rear
All Series (Exc. 98) 1946-47	28 lbs.	28 lbs.
Series 98, 1946-47	24 lbs.	24 lbs.
All Models 1948-51	①	①
All Models (Exc. 98 Convt.) 1952	24 lbs.	24 lbs.
98 Convt. 1952	22 lbs.	22 lbs.
All Models (1953) ②	24 lbs.	22 lbs.
All Models (1953) ③	26 lbs.	22 lbs.
All Models (1954)	24 lbs.	22 lbs.

①—6.00x16, 6.50x16, 6.50x15 (28 lbs.). 7.60x15, 8 00x15 (22 lbs.). 8.20x15 (22 lbs.).
②—Models without Air-Conditioning.
③—Models with Air-Conditioning.

Wheel Runout—Check wheels and tires for run-out. Must not exceed ⅛". Mark 'high' point on tire and place this mark at top (vertically) when checking Toe-in and Toe-out, at one side (horizontally) to check Caster, Camber & Kingpin Inclination.

Frame Height—Raise and lower front end of car several times by grasping front bumper to allow frame to come to normal level.

NOTE—Car weight must be on wheels and wheels should be set in straight ahead position when checking adjustment.

Kingpin Inclination—4°51'10" (All 1941-48), 4°29'47" (1949-52), 4°55'13" (1953), 5°51'10" (1954) crosswise. Not adjustable.

Caster: Must be equal within ½° on both sides. Machined bosses provided on front side of knuckle support for protractor mounting.

Caster Specifications

Oldsmobile (All Models) ..... 0° to Neg. ¾°

To Adjust—Loosen clamp bolt in upper end of knuckle support, remove lubricant fitting on front bushing of upper support pivot pin, insert Allen wrench J-720 through lubricant fitting hole and turn upper pivot pin clockwise to increase caster, counter-clockwise to decrease caster. CAUTION—Pin must always be turned in complete turns only to avoid disturbing camber adjustment (below).

Camber: Camber adjustment (upper pivot pin) eccentricity is 1/16". 3/32" pin is available from the Parts Dept. and can be installed if regular 1/16" pin does not give sufficient range of adjustment.

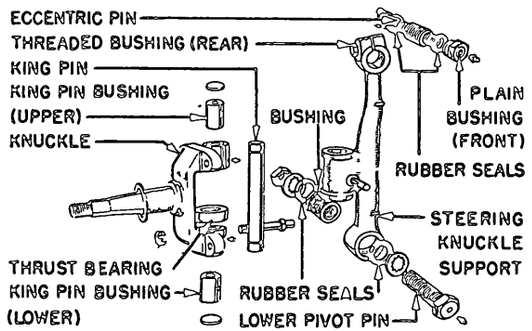
Camber Specifications

1946-48	Neg. ¼° to Pos. ¾°
1949-54	①Neg. ¾° to Pos. ¾°

①—New Car limits Neg. ¼° to Pos. ¾°.

To Adjust—Same as for Caster (above) except that entire range of adjustment secured in ½ turn of eccentric pivot pin. CAUTION—Do not turn pin more than ½ turn when adjusting camber to avoid disturbing caster adjustment.

Toe-In: Measure 9-10" above floor with wheels turned straight ahead.



Toe-In Specification

Oldsmobile (All Models) ..... 1/16-1/8"

To Adjust—Loosen clamp bolts at wheel end of each tie rod, turn tie rod adjuster on each rod equally. On Oldsmobile, turn both adjusters in direction opposite to that in which wheel revolves to increase toe-in.

Toe-Out on Turns: With outer wheel turned exactly 20°, inner wheel 23° ± ½°. No adjustment.

SERVICING: Lower Control Arm & Pivot Shaft. Serviced as an assembly and not interchangeable on right and left sides of car. Pivot shaft at inner ends of control arms can be removed by taking out bushing in each arm. To install shaft, install tool J-1052 or block between arms adjacent to shaft eyes so that distance between inner faces of arms at shaft eyes is exactly 11½" (necessary to prevent distortion of arms when bushings installed). Install shaft with seal on each end adjacent to mounting bracket, thread bushing in on shaft and in arm simultaneously (new bushings cut their own thread in arm as they are turned in), tighten bushings with 150 lb. pull on 16" wrench (200 lbs. on 12" wrench) so that there is no clearance between bushing flange and control arm. See that distance between shaft bracket mounting holes and inner face of control arm is exactly 1½" at each end (turn shaft to centralize), and that seal ends lap over bushings.

OLDSMOBILE FRONT SUSPENSION

Knuckle Support Lower Pivot Pin—To install pin, slip rubber seal over outer end of each lower control arm, center knuckle support between lower control arms (approximately ⅛" between end of bushing and front arm, same distance between head of bushing and rear arm). Screw pivot pin through front arm, knuckle support bushing, rear arm, install nut on rear end of pin. Pull seals down over end of arms so that they seat on pin between arm and bushing at each side.

Knuckle Support Upper Pivot Pin—To install, center knuckle support in upper control arm yoke, screw pivot pin in until larger center section is centered in knuckle support, tighten clamp bolt. Install seal on pin at each side, start front bushing in on pin, then screw rear bushing in control arm and on pin and tighten securely. Turn front bushing in until clearance between front face or arm and head of bushing 1/32", tighten clamp bolt.

Kingpin Installation (Oldsmobile)—Bushings should be installed with oil hole lined up with oil hole in knuckle support and short groove on inner surface leading from oil hole to outer end of bushing (up on top bushing, down on lower bushing). Bushings should be burnished with Tool Set J-1061 and line-reamed to size with Tool HM-592.

SPRINGS: Lower end of spring not ground flat and must be installed with end coil fitted into recess in lower spring seat. Upper end of spring is ground flat. CAUTION—Spring must be installed with flat (ground) end up and lower end fitted in spring seat.

Part Number Location—Stamped on lower end of coil.

Color Mark—Consists of one or two paint daubs on one spring coil.

COIL SPRING REPLACEMENT: Support car frame with car stands, center jack under lower control arm pivot shaft and disconnect stabilizer link. Disconnect pivot shaft from front cross-member. Lower jack from under pivot shaft, allowing control arm to drop out of position, and remove spring.

Installation—Reverse removal procedure and be sure that flattened top coil is toward top and centralized by four lugs on cross-member. Bottom must index with hole in spring seat.

SHOCK ABSORBER REPLACEMENT: Place jack under knuckle support and raise car and remove wheel. Remove upper pivot pin. Remove the four shock absorber mounting bolts (nuts inside cross-member must be held from turning). Remove shock absorber.

Servicing (Front Shock Absorbers): Unsatisfactory ride control may be due to lack of fluid or malfunction of shock absorber. (NOTE—Presence of an appreciable amount of oil under shaft bearings on outside of shock absorber usually indicates shaft bushings are worn or oil seal has failed. In either case, unit should be replaced without further examination). To test shock absorber action without removing from car, proceed as follows: Be sure shock absorber is securely mounted, then disconnect shock absorber arm at upper pivot pin. Holding shock absorber at approximately the same angle as installed on car, move shock absorber through complete travel. There should be no free travel in shock absorber arm and amount of force required to move arm up and down should be almost equal. If control of shock absorber defective, fluid level should be checked and shock filled if found to be low (See Filling Front Shock Absorber below). If fluid is at proper level, replace shock absorber. NOTE—If shock absorbers checked while removed from car, they should be checked in same position as when mounted.

Filling Front Shock Absorber: If shock absorber off car, place shock absorber on mounting block with filler plug tilted upwards approximately 15° from horizontal position. Remove filler plug and make sure shock is completely full of fluid.

CAUTION—It is important that front shock absorber be filled through filler plug with shock in above position, otherwise air may be locked in shock absorber.

Installation—Reverse removal procedure and check front end alignment.

1955 OLDSMOBILE

All Series (1955)

►CHANGES & CORRECTIONS

►*1955 PIVOT PIN PRODUCTION CHANGE (To Eliminate Need for Lockwashers):* Effective approximately July 1, 1955 new upper and lower pivot pins are used in production. New pins have head of bolt undercut, and a higher pitch thread diameter is used immediately under the head of the bolt. Changes cause locking action when bolt is tightened and eliminate need for lockwashers.

DESCRIPTION: New design independent "parallelogram" type with shock absorbers mounted within front coil springs. Shock absorbers are independent of upper control arm and can be removed and installed without disturbing upper control arm assembly.

ADJUSTMENT: Before checking and adjusting front wheel alignment, inflate tires to recommended pressure. Check front wheel bearings for proper preload. Check front wheel and tire assemblies for radial and lateral run-out. Grasp front bumper in center and raise and lower front end several times to allow frame to come to its normal level. Check front shock absorber action All specifications below, are for car at curb weight.

Tire Inflation Pressure: 24 lbs. (front), 22 lbs (rear).

Kingpin Inclination: 5°51'10" at 0° Camber. Not adjustable.

Caster: 0° to Neg. ¾°. Variation between wheels should not exceed ½°.

Adjustment—Loosen clamp bolt at upper end of steering knuckle support and using special wrench J-5343, turn eccentric bushing in a clockwise direction to increase caster, and in a counter-clockwise direction to decrease caster. *NOTE*—Before tightening clamp bolt, adjust camber (see below).

Camber: Neg. ¾° to Pos. ¾°. Variation between wheels should not exceed ½°.

Adjustment—Same as for caster (above). Turn eccentric bushing not more than ½ turn in either direction from point where correct caster secured. *NOTE—The entire range of camber adjustment is secured within ½ turn of eccentric bolt.*

Toe-In: 1/16" to 1/8".

Adjustment—Loosen clamp bolts at each end of steering tie rod adjustable sleeves. With steering wheel set in straight ahead position, turn tie rod adjusting sleeves to obtain the proper toe-in adjustment. *CAUTION*—After adjustment completed and tie rod end ball studs are square in their seats, position tie rod-to-relay rod ball studs to bottom of slot in relay, then position clamps so bolts are below upper surface of adjusting sleeves. End of clamp must not be in slot.

Toe-Out on Turns: With outer wheels turned 20°, inner wheel should be 23°±½°. Not adjustable.

SHOCK ABSORBER REPLACEMENT: *NOTE—It is not necessary to disturb front suspension assembly.*

Rem val—Remove nut and jam nut on upper end of shock absorber *(CAUTION—Flats are provided on upper stud so it can be held while loosening the nuts).* Remove three capscrews and lockwashers attaching shock absorber bracket to lower control arm, and remove shock absorber out through lower control arm spring seat.

Installation—Reverse removal procedure.

FRONT STABILIZER: Rem val—Disconnect stabilizer linkage, each side, by removing nut from top of link-bolt. Pull out bolt from bottom of linkage, and remove retainers, grommets, and spacer. Remove stabilizer bracket to frame bolts and remove stabilizer bar, rubber bushings and brackets.

Installation—Reverse removal procedure and note the the following: Rubber bushings should be positioned squarely in brackets and the nut retaining the stabilizer link assembly should be drawn down to the limit of the threads. *CAUTION—Never lubricate stabilizer bushings.*

COIL SPRINGS: Removal—Support car with floor stands. Disconnect stabilizer link from lower control arm and remove rubber bumper from lower control arm. Remove shock absorber (see above). Center jack pad under lower control arm pivot shaft and raise jack until it just contacts shaft, then disconnect pivot shaft from front crossmember. Lower jack slowly, allowing control arm to drop out of position until spring is fully extended and remove spring.

Installation—Place jack pad under lower control arm pivot shaft. Position rubber insulator over pilot in crossmember. Hold the upper end (flat end) of coil spring in crossmember and raise lower control arm until spring seat contacts lower coil of spring, then rotate spring so end of bottom coil will index in hole provided in spring seat. Raise control arm gradually, checking to see that spring is seated correctly top and bottom, and insulator is in place. Use a drift punch to line up pivot shaft with bolt holes in crossmember and install bolts. Tighten to 55-60 ft. lbs. Connect stabilizer link, and install shock absorber

►*COIL SPRING IDENTIFICATION NOTE:* Spring part number is stamped on the outside of one of the end coils.

Series	1955 Springs Spring Part N .
88 (Without Air Cond.) Synchro-mesh	566124
88 (Without Air. Cond.) Hydra-Matic	566125

98 Conv.	566127
98 (With Air Cond.)	566559

UPPER PIVOT PIN & ECCENTRIC BUSHING: R m val—Place jack under lower control arm and raise wheel off floor. Remove wheel and loosen knuckle support clamp bolt. Remove nut and washer from front end of pivot pin and remove threaded pivot pin. *(CAUTION*—To prevent damage to brake hose, fasten knuckle support to upper control arm with a short piece of wire). Remove threaded eccentric bushing from knuckle support (eccentric has left hand thread).

Installati n—Position pivot pin rubber seal over the outer ends of upper control arm to facilitate their in-

C NTINUED N NEXT PAGE

1955 OLDSMOBILE (C nt.)

stallation over the pivot pin after assembly. Install eccentric bushing from front into knuckle support so that the threaded outer diameter of bushing is centralized; then tighten clamp bolt to keep bushing from turning. Centralize knuckle support between forked ends of upper control arm and install pivot pin with shake-proof lock washer from rear. Install nut and tighten to 50-60 ft. lbs. Check to be sure pivot pin bolt head and nut are tightened securely against metal of control arm. Using a heavy wire or other hooked tool, snap rubber seals over end of control arm and into place on pivot pin. Lubricate pivot pin, install wheel, and check front end alignment.

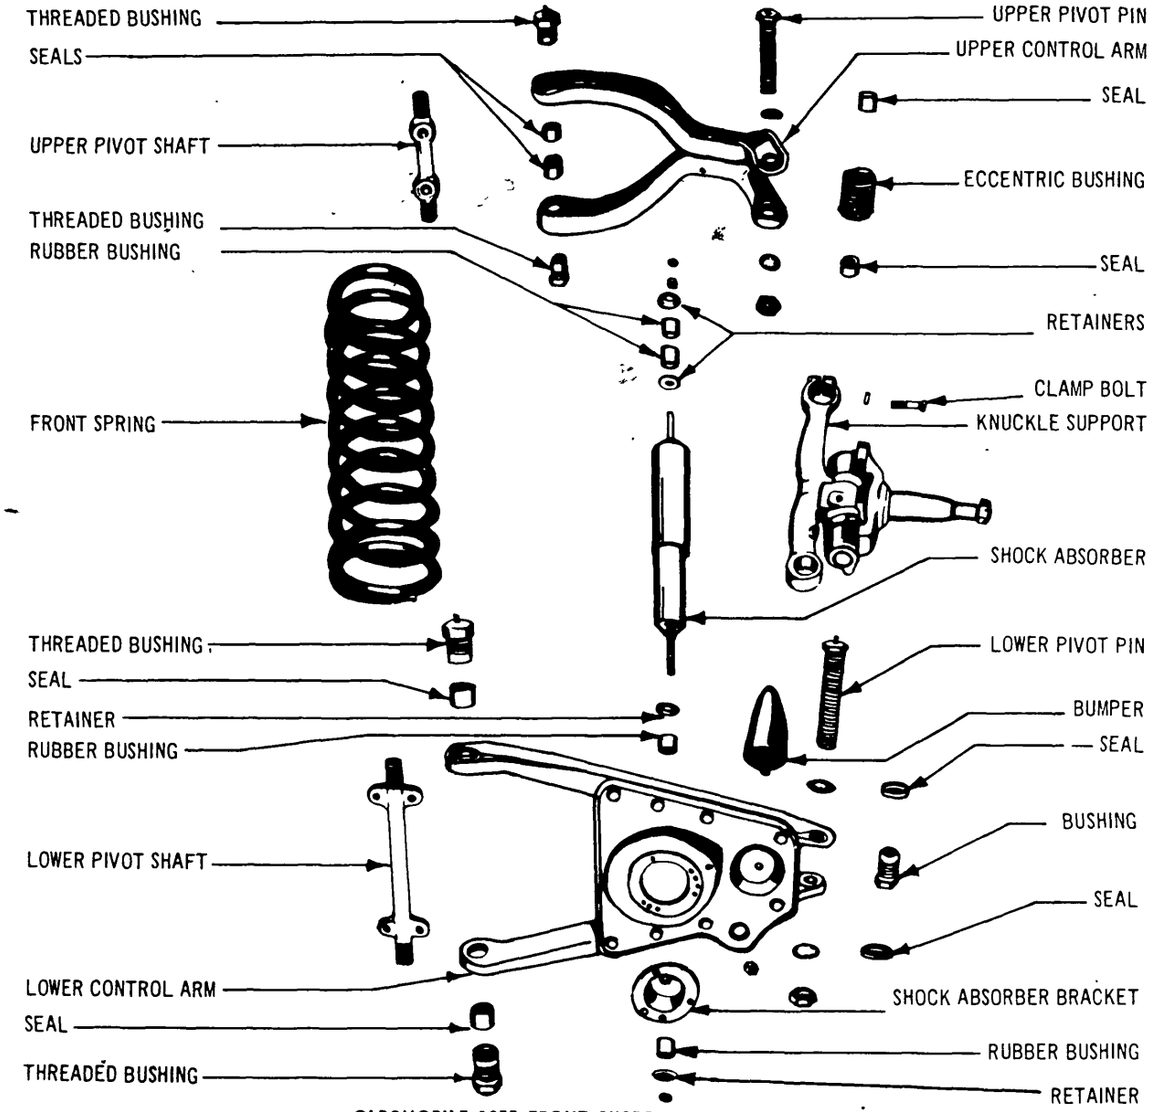
►*PIVOT PIN NOTE: See Production Change above.*

LOWER PIVOT PIN & BUSHING: Removal–Place jack under lower arm, raise wheel off floor, and remove wheel. Remove nut and lockwasher from front end of lower pivot pin. Remove pin and bushing (use a long handle socket wrench to remove bushing and bear down with other hand on brake drum hub when working on left hand side).

Installation–Position pivot pin rubber seals over forked outer ends of lower control arm. Install bushing into front of knuckle support and seat tightly. Centralize lower pivot pin bushing with knuckle support between forked ends of lower control arm and install pivot pin with shake-proof washer from the rear and tighten to 50-60 ft. lbs. *(NOTE*–When knuckle support is properly spaced between ends of lower control arm there should be approximately 1/8" clearance between ends of bushing and inner surface of the front and rear control arm). Install a shake-proof washer and pivot pin nut and tighten securely.

►*PIVOT PIN NOTE: See Production Change above.*

LOWER CONTROL ARM PIVOT SHAFT: Removal–Remove front coil spring (see above). *(NOTE–Before removing pivot shaft, loosen the bushings).* Unscrew pivot shaft bushings and remove shaft from lower control arm assembly. *NOTE*–The lower control arm pivot shaft bushings have threads on the inside and outside of the bushing. The inside of the bushing threads onto the pivot shaft, but the bushing cuts its own threads in the lower control arm



Installation–Install rubber seals on ends of pivot shaft and place shaft in lower control arm assembly. Start bushing on pivot shaft and into arm at same time, tighten bushing in place. Center pivot shaft between control arms and install the other bushing as above, being sure threads index so there is no bind. The distance between the center of the pivot shaft bolt holes and the inside face of the arm should be 1½" at each end. Turn pivot shaft as necessary to centralize. Position front coil spring on spring seat and complete assembly (see Coil Springs above).

LOWER CONTROL ARM: Removal–Remove coil spring (see above). Remove lower pivot pin and remove pivot shaft bushings and shaft.

New C ntr l Arm–Place tool J-1052 in position between forks of control arm, and expand until there is a distance of 11½" between inside surface of inner ends of control arm. Apply chassis lubricant to pivot shaft threads and install rubber seals on shaft. Position pivot shaft in control arm and while holding shaft centered, start bushings on shaft and into arms. Tighten bushings until they are solidly seated against the shoulder. Remove expander tool and turn shaft, as necessary, to centralize. Install lower pivot pin. Install coil spring (see above).

UPPER CONTROL ARM & PIVOT SHAFT: Removal–Remove upper pivot pin (see above). Remove two bolts holding upper control arm to frame and remove shaft and control arm assembly. Flat washers and self-locking nuts on lower end of bolts can be reached through access hole in bottom of front crossmember. Remove threaded pivot shaft bushings and shaft

New Control Arm–Place tool J-5799 in position between forks of control arm, and expand until there is a distance of 6 9/16" between inside surface of inner ends of control arm. Apply chassis lubricant to pivot shaft threads, and install rubber seals on shaft. Position pivot shaft in control arm and while holding shaft centered, start bushings on shaft and into arms. Tighten bushings until they are solidly seated against the shoulder. Remove expander tool and turn shaft, as necessary, to centralize. Complete assembly by reversing removal procedure.

OLDSMOBILE 1955 FRONT SUSPENSION ASSEMBLY

1946-50 PACKARD

Clipper Eight, Model 1951 (1941)
Six, 2000, 2010 (1942); 2100, 2130 (1946-47)
Eight, 2001, 2011 (1942), 2101, 2111 (1946-47)
Eight, "2200" & "2300" Series (1948-50)
Super Eight, 2003 (1942), 2103, 2123 (1946-47)
Super Eight, "2200" & "2300" Series (1948-50)
Custom Super 8, 2006 (1942), 2106, 2126 (1946-47)
Cust. Eight, "2200" & "2300" Series (1948-50)

TYPE: Independent 'parallelogram' type with coil springs. Design not like that used on other Packard models in that torque arm not used. Lower control arm consists of a double arm pivoted on a bracket shaft bolted on the front frame cross-member near the center with the lower spring seat riveted on the arms. Spring seat also serves as a mounting for the lower rubber bumper and has a connection for the front stabilizer bar link.

CHECKING & ADJUSTMENT: Check front wheel bearings and adjust if necessary, check wheels and tires for balance and run-out, check shock absorber action. Set front wheels in straight ahead position and check following points first:

Tire Inflation (1941-47)—Inflate tires to 26 lbs. (Front—Six), 28 lbs. (Rear—Six), 28 lbs. Front & Rear (All Other Models).

Tire Inflation (1948)—Inflate tires (front & rear) to following pressures (cold):

2201 & 2211 (exc. St. Sedan), 2206, 2240	28 lbs.
2201 & 2211 Station Sedans	26 lbs.
2202, 2232, 2233	26 lbs.
2220, 2222, 2226	32 lbs.

Tire Inflation (1949-50)—Inflate all tires (cold) to 24 lbs. (except Super 8 7 Pass.), 26 lbs. (Super 8 7 Pass. only).

Frame Height—Car must be loaded or pulled down to correct riding height when checking front end specifications as follows:
Front End—3½" from lower face of frame side rail to top of lower control arm.
Rear End—5" from lower face of frame side rail to top of rear axle housing.

Kingpin Inclination: As follows:

1941-47 All Models	5°35' Crosswise
1948 2232 & 2233 Convertibles	5°35' Crosswise
1948 2226 & 2213 Custom	2°30' Crosswise
1948 All Other Models	5°50' Crosswise
1949-50 All Models	5°50' Crosswise

Caster: As listed below with correct Frame Height.

Caster Specifications

1941-47 All Six & Eight	Neg. 1° ± ½°
1942-47 All Super & Cust. Super 8	Neg. 2° ± ½°
1948 Six 2220	Neg. 2° ± ½°
1948 Six 2240 & Eight 2201, 2211	Neg. 1° ± ½°
1948 Super 8 2202, 2232	Neg. 1° ± ½°
1948 Super 8 2222	Neg. 2° ± ½°
1948 Custom 8 (All Models)	Neg. 2° ± ½°
1949-50 Eight	Neg. 1° ± ½°
1949-50 Super 8 exc. 7 Pass.	Neg. 1° ± ½°
1949-50 Super 8 7 Pass.	Neg. 2° ± ½°
1949-50 Custom 8	Neg. 2° ± ½°

To Adjust Caster—Loosen clamp bolt in upper end of knuckle support, remove lubrication fitting in front bushing at outer end of upper control arm, install Allen type wrench, special tool No. KMO-487, through lubrication fitting hole so as to engage socket in end of upper pivot pin, turn this eccentric pin clockwise to increase caster, counter-clockwise to decrease caster in complete turns only, tighten clamp bolt and re-install lubrication fitting. NOTE —This pin also controls camber and camber will be disturbed unless pin turned in complete turns only

Camber: 0° plus or minus ½° (All Models).

To Adjust Camber—Adjusted in same manner as Caster (above) except that entire range of adjustment secured in ½ turn of the eccentric pin. NOTE —This adjustment affects Caster and will be satisfactory if pin turned not more than ½ turn from point where correct caster adjustment is secured.

Toe-In:—0-1/16" (all models). Measure between tires 10" above floor. When checking toe-in, first set wheels straight ahead and correct tie rod lengths, if required, as follows: With wheels straight ahead, line up mark on steering gear case with mark on roller cross-shaft to insure roller being on high midpoint of worm, install Center Gauge J-2556 on frame cross-member, adjust tie rods (lengthen one rod, shorten opposite rod) until distance from mark on gauge to brake backing plate is same on both sides of car. CAUTION—See that steering marks kept in alignment while making this adjustment.

To Adjust Toe-In—Loosen clamp bolts on adjusting sleeve at outer end of each tie rod, turn both adjusting sleeves equally (to avoid disturbing steering gear position). Make certain that ball joint socket is horizontal or square with ball stud when tightening adjusting sleeve clamp bolts. NOTE—If correct toe-in adjustment cannot be secured by turning both tie rods equally within ½ turn (tie rod lengths equal within ½") without turning steering gear off high point of worm, steering gear pitman arm should be relocated on cross-shaft.

Steering Geometry:—With outer wheel turned exactly 20°, inner wheel should be turned 23° plus or minus ½°. No adjustment is provided. Check for incorrect Caster or bent steering arms if incorrect.

SERVICING: Knuckle Support Upper Pivot Pin & Bushings—To assemble knuckle support and upper control arm, thread eccentric pivot pin in upper end of knuckle support until larger center section is centered in support with adjusting wrench socket toward front of car (approximately two threads exposed at rear of support), install clamp bolt in support and tighten securely, install seals on each end of pin (front seal approximately ⅛" shorter than rear). Hold knuckle support centered in end of upper control arm, thread rear bushing in arm and on pin partially, start front bushing on pin, then tighten rear bushing securely to 90-100 ft. lbs. Turn front bushing in until clearance between hexagonal head of bushing and front face of control arm is 1/32", install clamp bolt in front eye of control arm and tighten this clamp bolt securely.

Knuckl Support Low r Pivot Pin—Consists of a bolt threaded through eyes at outer end of lower control arm and a bushing which is threaded in knuckle support and on the bolt. Bolt is retained by a nut on the rear end. To assemble, install bushing in knuckle support, tighten bushing to 145-155 ft. lbs. Slip rubber seal over each end of bushing, hold knuckle support and bushing centered in lower control arm, thread bolt through arm and knuckle support bushing from front, install nut and washer on rear end of bolt, snap seals down over bushing and into place on the bolt at each end of bushing. NOTE—Clearance between inner face of control arm and end of knuckle support bushing should be ⅛".

Lower Control Arm Frame M unting Pivot Shaft—Control arm is pivoted on shaft bolted to frame cross-member by bushings which are threaded in arm and on shaft. Shaft can be removed from arm by removing bushings. New bushings cut their own thread in the arm and must be installed as follows: Install special spreader tool J-1052 between inner ends of lower control arm to maintain correct distance of 11½" (plus or minus 3/64") between inner faces of control arm while bushings being installed (expand tool until correct distance of 11½" is secured). Hold pivot shaft centered in end of control arm so that distance from center-line of frame mounting holes to inner face of arm is 1½" at each end, see that seals installed on each end of shaft. Start bushing on shaft and in arm at same time, tighten bushings securely to 145-155 ft. lbs. Check to see that arm pivots freely on shaft and that 1½" dimension at each end is maintained (shaft can be rotated to centralize it in arm).

SPRINGS: Removal & Installation—To remove spring, support car with jack under lower control arm, raise wheel 3-4" off floor, place jack stand under frame side rail, disconnect stabilizer link at lower control arm, install jack under lower control arm frame mounting bar (inner end), take out mounting bar bolts and nuts, lower jack slowly to relieve spring tension, lift spring out.

Installation. Install in same manner paying particular attention to spring marks (see Note below). Make certain that flattened (ground) end of spring is upward and centralized by four lugs on cross-member, see that lower end of spring indexes with hole in spring seat (lower end not flattened and must be properly installed in spring seat recess).

1946-47 Spring Specifications

Car Model	U. S.—Part No.	Can. & Exp.
2100	367653	387864
2101, 2111	373862	387865
2103, 2106	367740	387866

1951-55 PACKARD

All Models (1951-54)
5540 Series, Clipper (1955)

▷*SERIES 5560 (CLIPPER DELUXE) & SERIES 5580 (PACKARD) NOTE:* "Torsion Level" Suspension used on these models. Front End Alignment (as indicated below) is the same for both types of suspension.

DESCRIPTION: Independent, parallelogram "Broad-Beam" type with new design Upper Support Arm and Direct Acting Shock Absorbers.

CHECKING & ADJUSTMENT: First check and adjust front wheel bearings, wheel and tire balance and run-out, and tire inflation. Place car on level floor and check following:

Tire Inflation (1951): 24 lbs., front and rear.

Tire Inflation (1952): (2513) 30 lbs. front, 40 lbs. rear. (Others) 24 lbs, front and rear.

Tire Inflation (1953): 24 lbs., (Exc. 2626, 2613, & 2633).
2626 Series—26 lbs., front & rear.
2633 Series—36 lbs, front & rear.
2613 Series—30 lbs., front, 40 lbs., rear.

Tire Inflation (1954): As follows:
5413—30 lbs. front, 40 lbs. rear.
5426—26 lbs., front and rear.
5433—36 lbs., front and rear.
Others—(With Conventional Steering) 24 lbs. front, 20 lbs. rear. (With Power Steering) 22 lbs. front, 20 lbs. rear.

Tire Inflation (1955): 24 lbs., front and rear. *NOTE*—If more than four passengers, inflate to 26 lbs., front and rear.

Kingpin Inclination: (2513, 2613, 2633, 5413, 5433) 2°30'. (Others) 5°50'.

Caster: (2513, 2613, 2633, 5413, 5433) Neg. 2° ± ½°. (Others) Neg. 1° ± ½°.
Adjustment—Remove lubrication fitting in bushing at forward end of upper support arm outer pivot pin, use Allen wrench inserted through this hole to turn the pivot pin in complete revolutions only.

▷*CAUTION—Pin is eccentric and will disturb camber setting unless it is rotated in full turns only.*

Camber: (1951)—0° ± ½°. (limits Neg. ½° to Pos. ½°.)

Camber (1952-55): 0° plus ¾°, minus ¼°.
Adjustment—Same as for Caster (above) except that eccentric pin should be turned not more than one-half revolution from point where correct caster setting secured. Entire range of adjustment is secured in ½ turn of the pin.

▷*CAUTION—Caster will be disturbed if pin turned more than one-half revolution.*

Toe-In: 0", plus 1/16", minus 0" (0" to 1/16" range). Adjustment—Loosen clamp bolts at each end of adjusting sleeve at outer end of each tie rod, turn adjusting sleeves on both tie rods equally.

Toe-Out on Turns: With outer wheel at 20°, inner wheel should be 23° ± 1° (1951-53), 23 ¾° (1954-55). No adjustment (check for bent steering arms).

SHOCK ABSORBER REPLACEMENT: Raise car until there is sufficient clearance to permit shock absorber to be removed through hole in bottom of lower support arm. Using an offset screw driver, insert the tool in slot of shock absorber extension. While holding top of shock absorber extension, remove shock absorber nut, washer, grommet. From underneath lower support arm, remove nuts holding shock absorber retainer bracket to bottom of lower spring seat, and remove shock absorber.

Installation—Reverse the removal procedure. Tighten shock absorber stud nut to 12-18 ft. lbs., and the lower retaining bracket nuts to 15-18 ft. lbs.

▷*CAUTION—Make certain that rubber grommets and cup-shaped washers correctly assembled on upper and lower mounting studs.*

COIL SPRING REPLACEMENT: Raise front end of car and place a jack stand under frame side rail to rear of suspension cross-member. Remove stabilizer to frame horn attaching nuts. Disconnect stabilizer end from lower support arm and remove shock absorber. Remove the front wheel and place a jack under outer end of lower support arm and raise just enough to relieve pressure on lower support pivot pin. Remove the pivot pin nut and screw out the pivot pin. Lower jack slowly to allow support arm to go down, then remove coil spring.

Installation—Position spring in lower support arm with the flattened end of spring upward. Place jack under lower support arm near outer end, and raise jack until holes in outer end of support arm are in line with holes in knuckle vertical support lower bushing. Centralize knuckle support in support arm (there should be approximately ⅛" clearance between inner face of arm and each bushing). Install lower pivot pin in through the front of support arm and tighten to 85 to 95 ft. lbs. torque. Position end of front stabilizer rod in lower support arm. Insert "ears" of the stabilizer attaching clips in holes of support arm, and spring the clip over bottom edge with tool J-4654. Install shock absorber through bottom frame front cross-member opening with the extension extending out through top of cross-member. Slip the rubber grommet and washer over top end of shock absorber and install the nut. Tighten retaining nut to 12-18 ft. lbs. torque. Install front wheel, remove stand from under car and lower car to floor.

▷*SPRING INSTALLATION CAUTION*—Flattened end of spring must be upward and end of lower coil must be seated in recess in lower spring seat so as to cover the drain hole in the spring seat.

1951 Spring Identification

SPRINGS:	Part No.	Load Rating
200 exc. Convt.	395720	2040x90
200 Convt.	382374	2180x90
300 & 400	382374	2180x90

1952 Spring Identification

Model	Syn. Mesh & O.D.	Ultramatic
200 (All Models)	387806	395720
250 (Sport Coupe)	387806	395720

2633 Commercial	446208	387866
2613 Commercial	395726	

UPPER SUPPORT ARM REPLACEMENT: Support front end on jack placed under lower support arm, remove wheel and tire assembly. Unscrew front and rear bushings on outer pivot pin. Remove clamp bolt from upper end of knuckle support, unscrew pivot pin from support. Remove two mounting bolts from support arm inner shaft, lift support arm assembly off. To remove shaft from support arm, unscrew bushing from arm at each end of shaft.

▷*INSTALLATION CAUTION*—When installing inner pivot shaft bushings in arm, use Spreader Tool J-3957 to maintain arm alignment while screwing bushings in. After installing support arm on frame, hold knuckle support centered in arm while screwing bushings in arm and on pivot pin. Make certain rubber seals installed at inner end of each bushing.

LOWER SUPPORT ARM REPLACEMENT: Remove shock absorber and coil spring (see directions above). Remove nut and lockwasher from rear end of lower pivot bolt at outer end of arm, unscrew bolt from knuckle support and support arm, lift support arm assembly off. Remove pivot shaft by unscrewing bushing from arm at each end of shaft.

▷*INSTALLATION CAUTION*—When installing pivot shaft bushings in arm, use Spreader Tool J-1052 to maintain support alignment. Install rubber seal at inner end of each bushing.

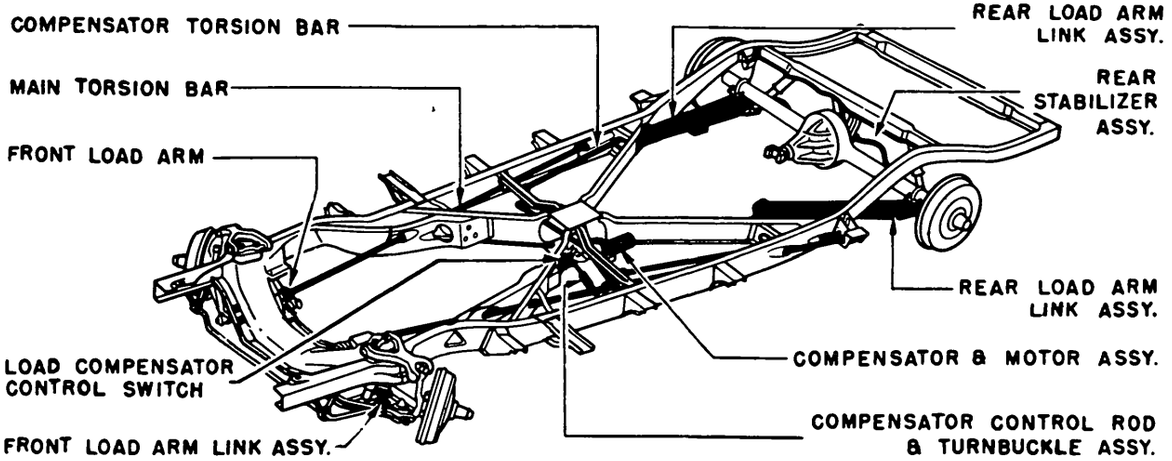
PACKARD FRONT SUSPENSION

PACKARD "TORSION LEVEL" SUSPENSION

5560 Series (Clipper DeLuxe) (1955)
5580 Series (Packard) (1955)

► CAUTIONS

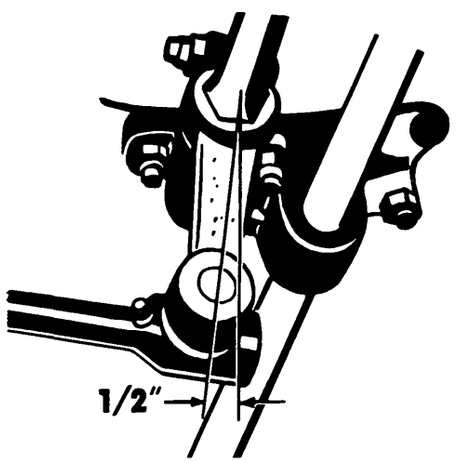
►*FRONT END ALIGNMENT NOTE: Alignment specifications are the same for "Conventional" & "Torsion Level" type suspensions. See "Packard (Conventional)" Front Suspension for data.*



►*SERVICING CAUTION: The "On-Off" Switch located below the instrument panel must be in the "OFF" position when cars "jacked-up" for service operations. DO NOT place jack or hoist under rear load arms as these may become disconnected.*

DESCRIPTION: Two long, torsionally flexible bars (running generally fore and aft along frame side rails) have hexagonal ends which fit into load arms (one at each end of each bar) which are hexagonally broached at one end. Front load arms pivot on anti-friction needle type bearings on brackets mounted on frame front cross member. Rear load arms also pivot on needle type bearings in brackets attached to frame side rails. Front arms are loaded against anti-friction links which seat in front suspension lower support arms. Rear arms are loaded against stirrup type links suspended from driving torque arms. Arms on each side are installed in such a manner that loaded ends are pointing in opposite directions (loaded end of front arm is pointing away from center of car whereas loaded end of rear arm is pointing toward center of car). Initial loading of arms is accomplished by "winding up" or twisting torsion bar during its assembly in chassis. Operating in conjunction with Torsion Level Suspension is a levelizing or compensating mechanism which automatically keeps car level and approximately at its designed height regardless of load.

Front Suspension: Except for minor design changes, the independent parallelogram type front suspension remains unchanged. Major change is elimination of coil springs.



Rear Suspension: Thrust of rear axle to frame, in order to move car, is accomplished by two driving torque arms, one at each side of frame, attached to frame at forward end by rubber cored bushings. Arms are also insulated by rubber at points of attachment to rear axle housing, permitting free movement of axle. Transverse or side-to-side movement of rear axle is controlled by two waved stabilizer bars which permit true vertical movement of rear axle. Rubber grommets, at ends of bars, insulate wheel shocks from frame.

Compensator: Basically, compensator consists of torsion bars approximately four feet long, connected by means of levers and links to a two-way motor with reduction gearing. Forward end of compensator bars rotate in bearings attached to frame. Hexagonal rear end of bars fit into rear load arms in milled hexagonal openings adjacent to main torsion bar openings. Bar type links are connected to the compensator gear box at their inner ends and, at their outer ends, to levers attached to front end of compensator bars. Six switches are used in compensator electrical system to control its operation. Control switch assembly is attached to frame forward of compensator motor. A lever in switch assembly is linked to a lever clamped to left main torsion bar near center of bar.

PACKARD TORSION LEVEL SUSPENSION ASSEMBLY

OPERATION: Torsion Level Suspension—Vertical wheel movement causes link end of load arms to move vertically. Vertical movement of either arm increases or decreases the amount of twist in the torsion bar which in turn transmits this twisting force to the arm on the opposite end of the bar and the load on the link end of this arm then is increased or decreased. The force beapplied to move front load arm is in an upward direction. The force opposing the movement of the rear load arm may be thought of as being in an upward direction. Therefore, the arms are being loaded against each other with the bar absorbing the torsional load. In addition to absorbing the torsional stresses created by road irregularities the load arms and torsion bars also function in a manner which raises or lowers the car, front and rear, on the side where road irregularity is encountered.

COMPENSATOR BAR "NO LOAD" POSITION

Compensator: With front and rear of car equally loaded, center section of main torsion bar has no rotation due to equal twisting forces being applied at each end of bar. When loading at either end of car is increased or decreased, center section of main torsion bar will rotate causing control switch to make contact and "make" and "break" circuit to compensator motor. This causes connecting links to move inward or outward to rotate compensator bars. The bars, in turn, cause rear load arms to pivot and either raise or lower rear end of car to make it level with front end. Thus, regardless of weight distribution, car remains level to road, front and rear, with very little change in car height. It should be remembered that compensator functions only when loading of car is changed and does not function to compensate for road irregularities. *NOTE*—Control switch has approximately a seven second delayed action to prevent motor from operating each time wheels pass over an irregularity in road.

Switches—Six switches used to control compensator as follows:

"On-Off" Switch—Located below instrument panel to left of steering column.

►*CAUTION: This switch is normally in "ON" position and is moved to "OFF" position to prevent compensator from operating when car is raised for service operations.*

Stop Light Switch—A three terminal two-way stop light switch is used to prevent compensator operation during brake application.

Control Switch—Used to energize compensator motor when car load is increased or decreased.

Limit Switch—Employed to permit compensator motor to operate only within a predetermined range in accordance with load changes in car.

Solenoid Switches—Two used to complete electrical circuit to compensator motor, one for each direction of rotation of the motor.

CONTINUED N NEXT PAGE

PACKARD "TORSION LEVEL" SUSPENSION (C nt.)

ADJUSTMENT: C mp nsator Linkage–Set car on its wheels. If rear end of car is too high, shorten compensator switch turnbuckle. If rear end too low, lengthen link.

LUBRICATION: Incorporates ten lubrication points which should be lubricated every 1000 miles with pressure gun grease. Whenever torsion bars are replaced or unloaded for other service operations, link seats should be lubricated with a special grease.

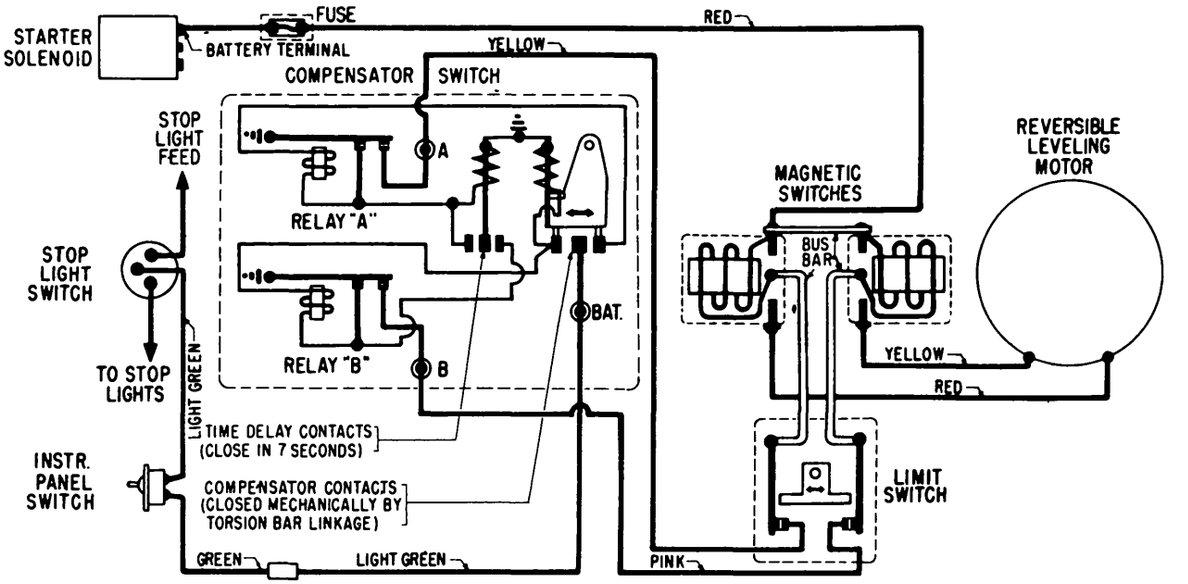
►*SERVICING CAUTION: Car should never be jacked in rear with jack r h ist under rear load arms as the rear l ad arm link may b com disconnected.*

TROUBLE SHOOTING (Electrical System): *NOTE–Two separat fuses ar used (one for leveling motor circuit, on for control circuit) and blown fuse in ither circuit will pr vent operation of compensator system.* If compensator does not operate, check as follows:

1)–Check control circuit fuse as follows: With dash compensator switch "On", apply the brakes. Stop lamps should light. If not, switch is disconnected or fuse is blown. *NOTE*–This fuse is the only 20 ampere fuse on the Fuse Block located under instrument panel near plenum chamber (fuse sizes are marked on holders).

2)–Check motor fuse as follows: Ground the "A". or "B" terminal on Compensator Switch mounted on left side of X-member directly forward of the leveling motor assembly (this switch has three terminals: "BAT", "A", "B"). Grounding of one terminal should cause motor to operate (grounding "A" terminal should lower rear end of car, grounding "B" terminal should raise rear end of car–see Note below). If motor does not operate in either direction, check for blown fuse. *NOTE*–This fuse is 20 ampere and located in cartridge type holder in lead near starter motor.

L v ling M t r N t –If compensator at limit of travel up or down, circuit will be broken by limit switch and grounding of compensator switch terminal will not cause motor to operate beyond this point. However, grounding of the other compensator switch terminal should cause motor to operate in opposite direction.



3)–Check wiring (see wiring diagram) and make certain that all connections are tight.

4)–If above checks indicate that trouble caused by malfunctioning Compensator Switch, Limit Switch, or motor control magnetic switches, replace units as required. Do not attempt to repair these parts.

L v ling M t r N t –Motor brushes and commutator can be serviced in same manner as for starter motors.

TORSION BAR REMOVAL: Position car on hoist and move the "on-off" switch, located under instrument panel to left of steering column, to the "off" position. Raise car and remove rear wheel on side from which torsion bar is to be removed. Proceed as follows:

1)–If a frame contact type hoist is used, place the high-jacks under rear axle housing and under the outer ends of front lower supports. On other type hoists, place the high-jacks at all four corners, front and rear, then extend jacks so that pads contact the frame.

TORSION LEVEL SUSPENSION CONTROL WIRING DIAGRAM

2)–Note position of compensator bar lever in illustration, as this is the position in which no load is being transmitted through the bar. Bar should be just off vertical toward the center. Move levers as necessary by grounding a terminal at the limit switch. Grounding rear terminal will move lever outward, front terminal will move lever inward.

3)–Remove nuts retaining rubber guide bearing and compensator retainer bracket to cross member and remove these parts. (*NOTE–If left tension bar is being removed, detach compensator link from compensator link from compensator bar).*

4)–Loosen rear load arm clamping bolt using an 11/16" socket and offset handle. Tap compensator bar forward and out of load arm. Slightly raise or lower rear hoist lift if required to centralize hex in arm with hole in bracket.

5)–Attach Load Arm Centering Tool J-6045 with piloting shoulder of tool in hole in bracket and opposite end of tool installed in elongated hole above compensating bar hole in bracket, tighten the locknut.

6)–Attach clamping detail of Torsion Bar Loading and Unloading Tool J-5954 at inner end of load arm and then install jack attachment to clamping detail. The hole in frame for attaching jack attachment is in line with the front of the brake drum. Operate jack to move inner end of load arm upward far enough to centralize the pivot bolt in bracket (pin is located between load bar and compensator bar holes in bracket). Use a brass drift and tap pivot bolt out of bracket.

7)–Tighten jack to move inner end of arm upward to clear load arm link and then move load arm link inward-Place a four inch block between rear axle case and bottom of frame "kick-up". While holding link inward, reverse tool ratchet and lower inner end of arm to relieve load on bar.

8)–Remove clamp from load lever and attach Removing Tool J-6046 to bar forward of bracket. Strike tool with a hammer and drive bar toward rear. Remove tool and push bar out toward rear.

TORSION BAR INSTALLATION: *CAUTION–An arrow is stamped in end of bar denoting direction in which bar must be "wound up". The three digits stamped in end of bar are the last three digits of bar part numb r.*

1)–Insert rear load arm in bracket and feed bar through bracket and load arm (if left bar being installed, feed bar through compensator link also), and into front load arm making sure that front load arm link is in correct position and that rear load arm is nearly vertical with clamping detail of Torsion Bar Loading and Unloading Tool J-5954, and Centering Tool J-6045 in place. Distance from rear end of torsion bar in load arm to rear face of bracket should be ¾" with rear load arm centered in bracket.

2)–Place special lubricant in seat in load arm link and connect tool jack to clamp on load arm. Operate jack and draw load arm up into position where pivot hole in arm lines up with pivot hole in bracket, and then insert pivot pin.

3)–Continue to draw upward while holding link inward until link can be swung outward under arm, then back off jack to seat arm.

4)–Position compensator bar in rear load arm and attach bearing at front of arm to frame (seal between bearing and lever should not be squeezed together but should contact both the bearing and lever). Tighten clamp nut in rear load arm. Remove clamp, jack, and centering tools.

5)–If left torsion bar replaced, attach compensator motor linkage so that rear edge of clamp lever is ¾" from front edge of rubber guide bearing retainer. Adjust compensator linkage (see above).

1946-48 PONTIAC

Six & Eight, All Models (1941-48)

DESCRIPTION: Linked parallelogram type with coil springs, and integral double acting shock absorbers.

CHECKING & ADJUSTMENT: Check and adjust front wheel bearings, check kingpins for looseness, check shock absorber action. Then check and adjust following points:

Tire Inflation: Check and inflate tires:

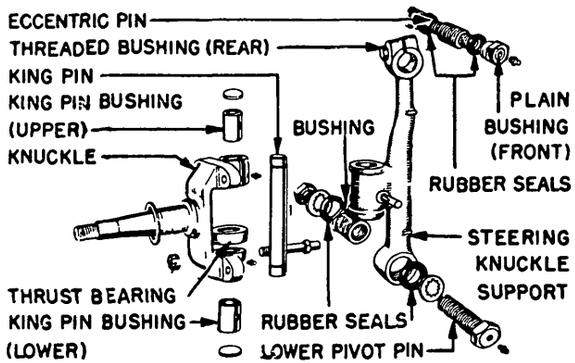
	Front	Rear
Pontiac All ('41-42)	28 lbs	28 lbs
Pontiac ('42)①	24 lbs	24 lbs.
Pontiac All ('46-48)②	28 lbs	28 lbs.
Pontiac All ('46-48)①	26 lbs	26 lbs.
Pontiac Sta. Wgn. ('46-47)③	32 lbs	32 lbs.
Pontiac Sta. Wgn. ('48) ③	27 lbs	36 lbs.

①—6.50x16 Tires. ②—6.00x16 Tires.
③—6 Ply 6.50x16 Tires.

Wheel Run-out: Wheel and tire run-out must not exceed ⅛". Mark "high" point of tire and place this mark at top (vertically) when checking toe-in and toe-out, place mark at one side when checking Caster, Camber, and Kingpin Inclination.

Kingpin Inclination: 5½-6° crosswise

Frame Height: Raise and lower front end of car several times to allow frame to assume normal level
NOTE—Car weight must be on wheels and wheels must be set in straight-ahead position when checking following specifications.



Caster: Neg. ¾° (Neg. ½° to Neg. 1°) and equal within ½° on both sides.
To Adjust—Loosen clamp bolt in upper end of knuckle support, remove lubricant fitting on front bushing of upper support pivot pin, insert Allen wrench J-720 through lubricant fitting hole and turn upper pivot pin clockwise to increase caster, counter-clockwise to decrease caster. CAUTION—Pin must always be turned in complete turns only to avoid disturbing camber adjustment (below).

Camber: 0°. Limits Neg ¼° to Pos ¼°
To Adjust—Same as for Caster (above) except that entire range of adjustment secured in ½ turn of eccentric pivot pin. CAUTION—Do not turn pin more than ½ turn when adjusting camber to avoid disturbing caster adjustment.

Toe-In: 0" to 1/16" measured 9-10" above floor.
To Adjust: Loosen clamp bolts at wheel end of each tie rod, turn adjuster on each rod equally and in opposite directions

Steering Geometry (toe-out on turns):—With outer wheel turned exactly 20°, inner wheel should be turned 23° ± ½°. No adjustment

SERVICING: Lower Control Arm & Pivot Shaft. Serviced as an assembly and not interchangeable on right and left sides of car. Pivot shaft at inner ends of control arms can be removed by taking out bushing in each arm. To install shaft, install tool J-1052 or block between arms adjacent to shaft eyes so that distance between inner faces of arms at shaft eyes is exactly 11½" (necessary to prevent distortion of arms when bushings installed). Install shaft with seal on each end adjacent to mounting bracket, thread bushing in on shaft and in arm simultaneously (new bushings cut their own thread in arm as they are turned in), tighten bushings with 150 lb. pull on 16" wrench (200 lbs. on 12" wrench) so that there is no clearance between bushing flange and control arm. See that distance between shaft bracket mounting holes and inner face of control arm is exactly 1½" at each end (turn shaft to centralize), and that seal ends lap over bushings.

Knuckle Support Lower Pivot Pin—To install pin, slip rubber seal over outer end of each lower control arm center knuckle support between lower control arms (approximately ⅛" between end of bushing and front arm, same distance between head of bushing and rear arm). Screw pivot pin through front arm, knuckle support bushing, rear arm, install nut on rear end of pin. Pull seals down over end of arms so that they seat on pin between arm and bushing at each side.

Knuckle Support Upper Pivot Pin—To install, center knuckle support in upper control arm yoke, screw pivot pin in until larger center section is centered in knuckle support, tighten clamp bolt. Install seal on pin at each side, start front bushing in on pin, then screw rear bushing in control arm and on pin and tighten securely. Turn front bushing in until clearance between front face or arm and head of bushing 1/32", tighten clamp bolt.

Kingpin Installation—Bushings are floating type and should be installed with lubrication groove on inner face leading toward outer end of bushings (up on top bushing, down on lower).

SPRINGS:—Lower end of spring not ground flat and must be installed with end coil fitted into recess in lower spring seat. Upper end of spring is ground flat. CAUTION—Spring must be installed with flat (ground) end up and lower end fitted in spring seat.

1941 Spring Specifications

Car Model	Spring Part No.
24, 26, 27 (exc. Sta. Wgn.)	509039
24 Station Wagon	509040
25 (exc Taxicab)	509037
25 Taxicab	509039
26 Taxicab	509040
28, 29	509040

1942-48 Spring Specifications

25 Torpedo 6 (except Convt. & Taxi)	509037
26 Strmlnr. 6 (exc. Sta. Wgn. & Taxi)	509039
27 Torpedo 8 (except Convt.)	509039
28 Strmlnr. 8 (except Sta. Wgn.)	509040
25 & 27 Convertibles	509038
25 Taxicab	509039
26 Taxicab	509040
26 & 28 Station Wagon	508116

1949-52 PONTIAC

All Models (1949-52)

►*1949-52 REBOUND NOISE CORRECTION*—If upper control arm strikes frame on extreme rebounds (causing loud metallic noise), replace standard bumper with higher bumper to prevent this contact (NOTE—Change bumpers on both sides)

Upper Control Arm Bumper

Standard (1¾" long) ..... **Part No. 1298323**
Special (2¼" long) ..... **Part No. 3687670**

DESCRIPTION: "Wishbone," independent, and linked parallelogram type with direct acting shock absorbers mounted within the coil springs, and new type upper control arm (not part of shock absorber assembly). Cross-member on which suspension unit mounted has separate brackets for upper control arm shaft mounting, for shock absorber mounting.

CHECKING & ADJUSTMENT: First check entire front end for wear and excessive play, inflate tires to correct pressures (see data below), check steering gear adjustment, wheel bearing adjustment, wheel and tire balance and run-out (run-out should not exceed 1/8"). Place car on level floor, "jounce" car at rear and front (see Leveling instructions) and check frame height. Then check and adjust all front end specifications in following order:

Leveling Frame: Jounce the car at the rear and then at the front end by grasping the bumper and raising and lowering the car violently at beginning to loosen up the suspension action and then with diminishing pressure until it finally comes to rest. Then measure frame height.
Frame Height—Measure vertical distance from underside of frame rail to top of lower control arm on each side of car. Distance should be the same on on each side of car. Unequal heights indicate sagged springs. See spring data.

Tire Inflation Pressure: For each tire size (Cold)
7.10x15 (Std.)—24 lbs. Front & Rear.
7.60x15 (Optl.)—22 lbs. Front, 20 lbs. Rear.
7.10x15 (Sta. Wgn. & Sedan Del.)—28 lbs. Front, 30 lbs. Rear.

Kingpin Inclination: 5° at 0° camber

Caster: Neg. ¾° ± ½°.
Adjustment—Loosen clamp bolt in upper end of knuckle support, use special wrench J-2998 to engage hexagonal head of bushing on pivot bolt in upper end of support, adjust caster by turning bushing in complete turns only to avoid disturbing camber.
►***CAUTION*—Clearance must be maintained between ends of bushing and control arm throughout suspension unit travel. Check for binding when adjusting caster.**

Camber: 0° ± ½°.

C NTINUED N NEXT PAGE

1949-52 PONTIAC (Cont.)

Adjustment—Same as for Caster (above) except that eccentric bushing should be turned not more than ½ revolution from point where correct caster secured (entire range of adjustment secured in ½ revolution of the bushing).

▷*ADDITIONAL RANGE OF ADJUSTMENT*—If correct camber cannot be secured by above adjustment, greater range of adjustment can be secured by taking out mounting capscrews in upper control arm shaft (on frame bracket at inner end of arm) and turning shaft over so that offset mounting holes tend to move shaft and control arm outward. This will provide approximately 2/3° additional camber.

▷*NOTE*—Control arm shaft is installed at factory with notch on side of shaft toward engine. When shaft turned over for increased camber, notch will be outward or toward wheel.

Toe-In: 0" to 1/16" measured 9" above floor.

Adjustment—Loosen clamp bolts at each end of adjusting sleeve at outer end of each tie rod, turn adjusting sleeves on both tie rods equally.

Toe-out on Turns: With inner wheel turned exactly 20°, outer wheel should be turned 18-19°. No adjustment. Check for bent steering arm if not correct.

SHOCK ABSORBER REPLACEMENT: *Not necessary to disturb Front Suspension Assembly.* Shock absorbers can be removed from below or above as desired.

Removal (from below)—Remove locknut and retainer nut on shock absorber upper stem at mounting bracket on frame, lift off upper grommet retainer and upper grommet (*NOTE*—If shock absorber turns when removing retainer nut, remove unit from above—see directions below). Remove three screws holding shock absorber lower mounting bracket on underside of spring seat on lower control arm, lower shock absorber and mounting bracket assembly out through hole in spring seat.

Removal (from above)—Jack up car, remove locknut and retainer nut from shock absorber lower stem at mounting bracket on underside of lower control arm (use pliers inserted through spring coil to keep shock absorber from turning), remove lower grommet retainer and lower grommet. Remove two nuts on shock absorber upper mounting bracket studs, lift shock absorber and upper mounting bracket assembly up and out through opening in frame above front wheel.

▷*INSTALLATION CAUTION*—Hold shock absorber from turning (with pliers inserted between spring coils) when tightening mounting nuts.

UPPER CONTROL ARM REPLACEMENT: *Upper pivot pin and eccentric bushing can be replaced without removing control arm from car.*

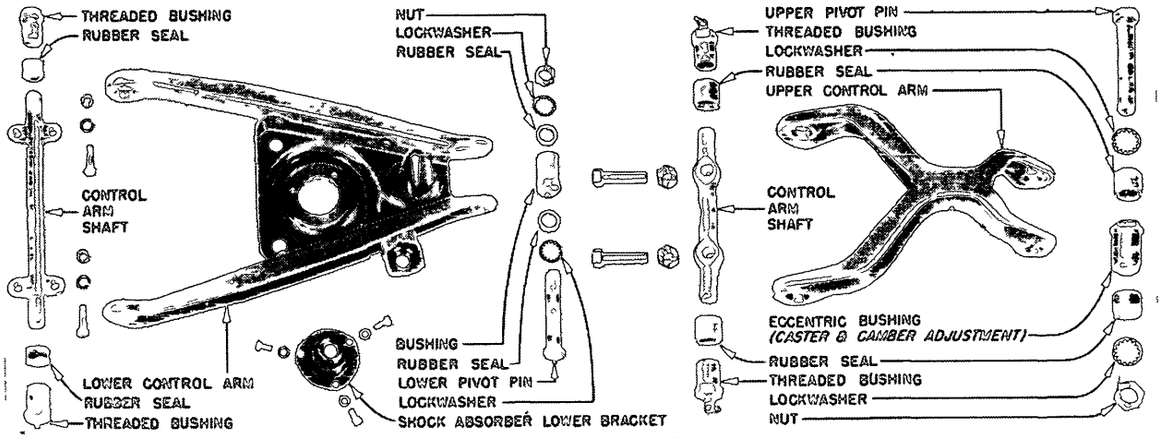
Removal: Support car with jack placed under lower control arm, remove wheel and tire. Remove shock absorber and upper bracket (see Shock Absorber Replacement). Take off nut on rear end of upper pivot pin, unscrew threaded pivot pin from knuckle support and control arm (CAUTION—wire knuckle support to frame to prevent damage to brake hose). Loosen clamp bolt in knuckle support, unscrew eccentric bushing from support. Take out two bolts mounting inner control arm shaft on frame, lift off control arm and shaft assembly.

▷*NOTE:* Note position of notch in shaft before removing shaft from control arm so that new shaft can be installed in same position.

Pivot Shaft Installation: Use spreader tool J-4251 to expand inner end of control arm to 7½" (measured between outer faces of arm). Position pivot shaft (with new rubber seal on each end) in control arm, lubricate shaft threads with chassis lubricant, start bushing on shaft and into eye in arm at same time, tighten bushing to 326-380 ft.lbs. torque and make certain that bushing flange firmly seated against arm. Center pivot shaft in arm (distance from shaft mounting hole center to outer face of arm should be 2" ± 3/64" at each end). Install second bushing. Remove tool and check control arm dimension (7½ ± 1/16" between outer faces of arm at pivot shaft), check pivot shaft position and center shaft by rotating it in the bushings. Check pivot shaft for freedom of movement (frictional drag of shaft should not exceed 12 in. lbs.). Position upper control arm and shaft on frame crossmember and install two bolts and self-locking nuts. Torque nuts to 60-65 ft. lbs.

Upper Pivot Pin & Eccentric Bushing Installation: Install new rubber seal on inner face of control arm eyes (slip end of seal over boss, double other end back to allow clearance for assembly). Install eccentric bushing in knuckle support. Hold knuckle support centered in upper control arm, thread pivot pin through control arm and bushing (coat pin threads with chassis lubricant, see that one lockwasher placed under head of pin) and tighten pin against arm with 50-55 ft. lbs. torque, then install pivot pin nut and lockwasher with 50-55 ft. lbs. torque. Turn ends of seals back to cover pivot pin threads.

Control Arm Installation: Notch on side of inner pivot shaft should face toward center of car (camber will be increased 2/3° if shaft turned over—see Camber Adjustment). Tighten pivot shaft mounting bolt nuts to 60-65 ft.lbs. torque.



LOWER CONTROL ARM REPLACEMENT: *Lower pivot pin and bushing can be replaced without removing control arm from car.*

Removal: Remove shock absorber (see shock absorber data), then proceed as for front spring removal (above). After spring removed, remove nut on rear end of lower pivot pin, unscrew pivot pin from knuckle support and control arm, lift control arm and pivot shaft assembly out.

Pivot Shaft Installation: Use spreader tool J-1052 to expand inner end of control arm to 11½" (measured between inner faces of arm). Position pivot shaft (with new rubber seal on each end) in control arm, lubricate shaft threads with chassis lubricant, start one bushing on shaft and into threads in arm at same time, tighten bushing to 385-455 ft.lbs. torque and make certain that bushing flange firmly seated against arm. Center shaft in arm (distance from shaft mounting hole centers to inner face of arm should be 1½" ± 3/64" at each end). Install second bushing similarly. Remove tool and check control arm dimension (11½"±3/32" between inner faces of arm at pivot shaft), check pivot shaft position and centralize it by rotating shaft in bushings.

Lower Pivot Pin & Bushing Installation: Install new bushing in lower end of knuckle support and tighten to 250 ft.lbs. (CAUTION—Bushings must be firmly tightened and bushing shoulder must be seated against support). Position new rubber seal on each end of bushing, hold knuckle support centered in lower control arm, thread pivot pin through control arm and bushing (coat pin threads with chassis lubricant, see that one lockwasher placed under head of pin), tighten pin against arm with 50-55 ft. lbs. torque, then install pivot pin nut and lockwasher, tighten nut to 50-55 ft. lbs. torque. Check knuckle support for centralized position (distance from end

CONTINUED ON NEXT PAGE

PONTIAC CONTROL ARM ASSY.

1949-52 PONTIAC (C nt.)

of bushing to inner face of control arm must be equal within one thread or ⅛" at each end of bushing).

KNUCKLE SUPPORT REMOVAL (For Kingpin Bushing Replacement): Take out brake backing plate mounting bolts and hang backing plate up out of the way (not necessary to disconnect brake line). Then remove upper and lower pivot pins (see Upper & Lower Control Arm replacement data).

SPRINGS: Springs have upper end flattened and lower end must be fitted in recess in lower seat. Color marks located on outside surface of spring center coil (if service springs not color marked, part number will be found on outside surface within 8" of top end measured on outer circumference).

COIL SPRING REPLACEMENT: Disconnect lower end of stabilizer link and remove shock absorber on side on which spring being removed. Lift front end of car with chain hoist or with jacks placed under frame side rails. Place additional jack under lower spring seat on control arm. Disconnect lower control arm from knuckle support by removing locknut and unscrewing lower pivot bolt. Lift car slowly (or lower jack under control arm) to relieve spring tension, lift spring out.

►***INSTALLATION CAUTION***—Install spring with flatted end at top and centered within positioning lugs on cross-member. See that end coil at bottom is fitted into spring recess in lower spring seat.

1953-55 PONTIAC

All Models (1953-55)

►CHANGES, CAUTIONS, CORRECTIONS

►*1953 & LATER PARTS REPLACEMENT CAUTION:* Front suspension parts are not interchangeable with previous model cars.

►*1953 FRONT SHOCK ABSORBER UPPER BRACKET MOUNTING CAUTION:* A few cars built prior to January 15, 1953 have one inch bolts installed to attach upper bracket to frame. Use of bolts longer than ¾" will cause interference with top coil of front spring causing squeak or failure of spring to seat properly. When these complaints encountered replace incorrect bolts with cadmium plated 5/16"–24x3/4" hex. head bolts, Part No. 181595.

DESCRIPTION: Independent linked parallelogram with direct acting shock absorbers mounted within coil springs.

CHECKING & ADJUSTING: Check entire front end for wear and excessive play, inflate tires to correct pressures, check steering gear adjustment, wheel bearing adjustment, wheel & tire balance and run-out (run-out should not exceed 1/8"). With car on level floor, jounce both ends (see Leveling instructions) and check frame height. Check and adjust front suspension assembly in following order:

Leveling Frame: Jounce car at the rear and then at the front and allow car to settle to normal operating position. Measure frame height.

Frame Height—Measure vertical distance from underside of frame side rail to top of lower control arm on each side of car. Distance should be the same on both sides of car. Unequal heights indicate sagged springs. See Spring Data below.

Tire Inflation Pressure: With tires COLD inflate to following pressures:

7.10 x 15 – 24 lbs.. Front & Rear.
7.60 x 15 – 22 lbs., Front 20 lbs., Rear.
7.10 x 15 (Sta. Wgn.)–28 lbs., Front. 30 lbs., Rear.
7.60-15 (Sta. Wgn.)–26 lbs., front and rear.
7.60-16 (With Air Cond.)–24 lbs. front, 20 lbs. rear.

Kingpin Inclination: 4½° at ½° camber (1953-54), 1°20' (1955).

Caster: 0°±½° (1953-54), Neg. 1°±½° (1955).

Adjustment—Loosen clamp bolt in upper end of knuckle support, use special wrench J-5343 to engage hexagonal head of bushing on pivot bolt in upper end of support, adjust caster by turning bushing in **complete turns only to avoid disturbing camber.**

►*CAUTION:* Clearance must be maintained between ends of bushing and control arm throughout suspension unit travel. Check for binding when adjusting caster.

Camber: Pos. ½°±½°.

Adjustment—Same as for Caster (above) except that eccentric bushing should be turned not more than ½ revolution from point where correct caster secured, (entire range of adjustment secured in ½ revolution of bushing).

Toe-In: 0" to 1/16" measured 9" from floor.

Adjustment—Loosen clamp bolts at each end of adjusting sleeve at outer end of each tie rod, turn adjusting sleeves **on both rods equally.**

Toe-Out on Turns: With inner wheel turned 20°, outer wheel should be 18-19°.

SHOCK ABSORBER REPLACEMENT: *Not necessary to disturb front suspension assembly.* Shocks remove from above upper control arm. Raise car so weight is off front wheels. Remove nut from bottom stud on shock absorber (hold shock with water pump pliers). Remove grommet and retainer and compress shock as far as possible by pushing lower section up. Remove two nuts holding shock bracket to frame (on left side of car, remove bracket from shock first). Shock can be removed through hole in frame. Install shock absorber with shock compressed, into spring, then extend shock so nuts and grommet can be installed on lower end.

UPPER CONTROL ARM REPLACEMENT: *Upper pivot pin and eccentric bushing can be replaced without removing control arm from car.*

Removal: Support car with jack placed under lower control arm and remove wheel. Remove shock absorber and upper bracket (see Shock Absorber). Take off nut on rear end of upper pivot pin, unscrew threaded pivot pin from knuckle support and control arm (CAUTION—Wire knuckle support to frame to prevent damage to brake hose). Loosen clamp bolt in knuckle support, and unscrew eccentric bushing. Take out two bolts mounting inner control arm shaft to frame (the nuts can be reached through access hole in front cross member).

Pivot Shaft Installation: Use spreader tool J-5324 to expand inner end of control arm to 6 9/16" (measured between inner faces of arm). Place pivot shaft with new rubber seals in position in control arm. After lubricating pivot shaft threads with chassis grease, start bushing on pivot shaft and into arm at same time. Tighten so bushing flange is firmly seated against control arm (326-380 ft. lbs. torque). Center pivot shaft in control arm and start other bushing being sure threads index so there is no bind. Tighten in same manner as other bushing. Remove spreader tool. Check to see that distance between inner faces of control arm is 6 9/16". Rotate shaft to centralize it so that bolt hole at each end of shaft is an equal distance from arm. *NOTE*–Frictional drag of shaft in bushings should not exceed 12 in. lbs.

Upper Pivot Pin & Eccentric Bushing Installati n: Install new rubber seal on inner face of control arm eyes (slip end of rubber seal over boss, double other end back to allow clearance for assembly). Install eccentric bushing in knuckle support. Hold knuckle support centered in upper control arm, thread pivot pin through control arm and bushing (coat pin threads with chassis lubricant, see that one lockwasher placed under head of pin) and tighten pin against arm with 50-55 ft. lbs. torque, then install pivot pin nut and lockwasher and tighten to 50-55 ft. lbs. torque. Turn pivot pin seals back to cover pivot pin threads.

CONTINUED ON NEXT PAGE

1953-55 PONTIAC (C nt.)

C ntr l Arm Installati n: Position upper control arm on frame cross member and install bolts and nuts. Tighten nuts to 80-85 ft. lbs. torque (nuts are self-locking and must be tightened with an extension inserted through hole in front cross member).

LOWER CONTROL ARM REPLACEMENT: *Lower pivot pin and bushing can be replaced without removing control arm from car.*

R m val: Remove shock absorber (see Shock Absorber data) then proceed as with Front Spring Removal. After spring removed, remove nuts and lock washers holding lower control arm shaft to frame cross member and remove control arm and shaft assembly. Remove shaft from control arm by removing front and rear threaded bushings from shaft and control arm.

Pivot Shaft Installation: Use Spreader Tool J-1052 to expand inner end of control arm to 11½" (measured from inner faces of arm). Position pivot shaft (with new rubber seals) in control arm, lubricate shaft threads with chassis lubricant, start one bushing on shaft and into threads in arm at the same time, tightening bushing to 385-455 ft. lbs. torque and firmly seated against arm. Center shaft in arm (distance from shaft mounting hole centers to inner face of arm should be 1½"±3/64" at each end). Install second bushing similarly. Remove tool and check control arm dimension (11½"±3/32" between inner faces of arm at pivot shaft), recheck pivot shaft position and centralize it by rotating shaft if necessary.

L w r Pivot Pin & Bushing Installation: Install new bushing in lower end of knuckle support and tighten to 250 ft. lbs.(CAUTION—Bushings must be firmly tightened and bushing shoulder must be seated against support). Position new rubber seal on each end of bushing, hold knuckle support centered in lower control arm, thread pivot pin through control arm and bushing (coat pin threads with chassis lubricant, see that one lock washer placed under head of pin) and tighten pin against arm with 50-55 ft. lbs. torque, install pivot pin nut and lockwasher, tighten to 50-55 ft. lbs. torque. Check knuckle support for centralized position (distance from end of bushing to inner face of control arm must be equal within one thread or 1/8" at each end of bushing).

KNUCKLE SUPPORT REMOVAL (For Kingpin Bushing Replacement): Remove brake backing plate and hang plate up out of way (not necessary to disconnect brake line). Remove upper and lower pivot pins (see Upper and Lower Control Arm data above).

SPRINGS: Upper end of springs are flattened and lower end must be fitted in recess in lower seat. Color marks located on outside surface of spring center coil

①—Same spring used with air conditioned cars.
②—Cars without Air Conditioning.
③—Cars with Air Conditioning.

COIL SPRING REPLACEMENT: Disconnect lower end of stabilizer link and remove shock absorber on side on which spring being removed. Lift front end of car with chain hoist, or with jacks placed under frame side rails. Place additional jack under lower spring seat on control arm. Disconnect lower control arm from knuckle support by removing locknut and unscrewing lower pivot bolt. Lift car slowly (or lower jack under control arm) to relieve spring tension, lift spring out.

►*FRONT SWAY BAR INSTALLATION CAUTION:* Sway bar must be installed with the proper side up or grommets may be damaged due to improper contact with eye in bar.

►*1953 FRONT SPRING RATTLE CORRECTION:* Check by striking spring with rubber hammer while pushing up and down on front of car. Rattle will be found at only one spring height. To correct, remove spring and cut semi-circular strip from 1/8" rubber about 3 long, the same shape as top of the spring coil. Clean all paint and grease off lower side of top coil and apply Plio-bond No. 30 to this surface and to surface of rubber strip, and apply strip to point where spring has been vibrating (shiny spot on spring).

1947-49 STUDEBAKER PLANAR

Champion, 6G (1947), 7G (1948), 8G (1949)
Commander & Land Cruiser, 14A (1947), 15A (1948) 16A (1949)

►CHANGES & CORRECTIONS

►***1947-48 PRODUCTION CHANGES: Due to production changes as listed below, indicated parts not interchangeable on cars produced before and after these changes. Serial number should be noted when ordering these parts:***

►**Champion 7G (1948) Steering Knuckle & Wheel Bearing Change:** Following parts changed at Serial No. G-337,462 (South Bend) and **not interchangeable with parts on earlier cars:** Steering Knuckle (Right & Left), Front Wheel Hub and Drum (Right & Left), Inner & Outer Wheel Bearing Assemblies (Bearing Cup, Cone & Rollers), Brake Drum Oil Catcher, Felt Grease Washer & Retainer Assembly.

►**Commander 14A (1947) Caster Change:** Caster changed to —2° to —3° beginning with following numbers:
Comm. 14A—Serial No. 4,276,243 (South Bend) & 4,819,208 (Los Angeles).
Comm. 14A Convertible—4,276,102 (South Bend).
Land Cruiser 14AY—4,276,053 (South Bend), & 4,819,188 (Los Angeles).
Other Cars—Following cars also have new Caster specification: 4819196, 4819200, 4819201, 4819177, 4819180, 4819185.

►**Commander 14A (1947) Front Suspension Parts Change:** At same time Caster changed (see above) parts listed below were changed and **are not interchangeable with parts used on earlier cars:** Steering Knuckle (Right & Left), Steering Knuckle Shims, Steering Knuckle Arm (Right & Left), Steering Knuckle Upper Bushing (Early Cars) and Bearing Rollers (Later Cars), Steering Knuckle Upper Control Arm Support (Right & Left), King Pin (Right & Left), and King Pin Thrust Bearing.

DESCRIPTION: Planar type independent suspension with transverse spring. Design changed from type used on 1946 Champion and previous Studebaker models.

CHECKING & ADJUSTMENT: Check front wheel bearing adjustment, tire inflation pressure, steering gear adjustment, shock absorber action, and steering linkage. Then check front suspension as follows:

Tire Inflation Pressures: For each tire size (Cold):
Champion—(5.50x15 & 5.50x16) 30 lbs. Front, 28 lbs. Rear. (6.00x15) 28 lbs. Front, 26 lbs. Rear. (6.40x15) 28 lbs. Front, 24 lbs. Rear.
Commander—(6.50x15) 26 lbs. Front, 22 lbs. Rear.

Kingpin Inclination—5½° crosswise.

Camber: (1947-48) ½° plus or minus ¼°.
(1949) 0° to Pos. 1° with ½° greater camber for left wheel than for right wheel.
Camber is controlled by number and thickness of slotted shims installed between each upper control arm bracket and frame.
To Adjust—Loosen upper control arm mounting bracket bolts, add shims (to increase camber), remove shims (to decrease camber) **equally at each bracket.** One thin shim will change camber approximately ¼° (thick shim equal to 4 thin shims).
CAUTION—Number and thickness of shims at each contr l arm bracket must be kept equal.

Caster: Not adjustable. Incorrect caster indicates bent parts or incorrect assembly (kingpin support not properly centered in control arms etc.).

►***PRODUCTION CHANGE NOTE—See 1947-48 Production Change Note for new parts and changed specifications.***

Caster Specifications

1947-48 Champion 6G & 7G	0° to Pos.1°
1949 Champion 8G	Pos. ½° to Pos. 1½°
1947 Early Comm. & Land Cr. 14A	0° to Pos. 1°
①1947 Later Comm. & Land Cr. 14A	Neg. 2° to Neg. 3°
①1948 Comm. & Land Cruiser 15A	Neg. 2° to Neg. 3°
1949 Comm. & Land Cr. 16A	Neg. 2° to Neg. 3°

①—See 1947 Production Change Note for Serial Nos. at which this change made.

Toe In: 1/16-⅛". Do not adjust toe-in until wheels correctly positioned and entire steering linkage checked and adjusted as follows:

►**1947-48 Adjustment Procedure:**

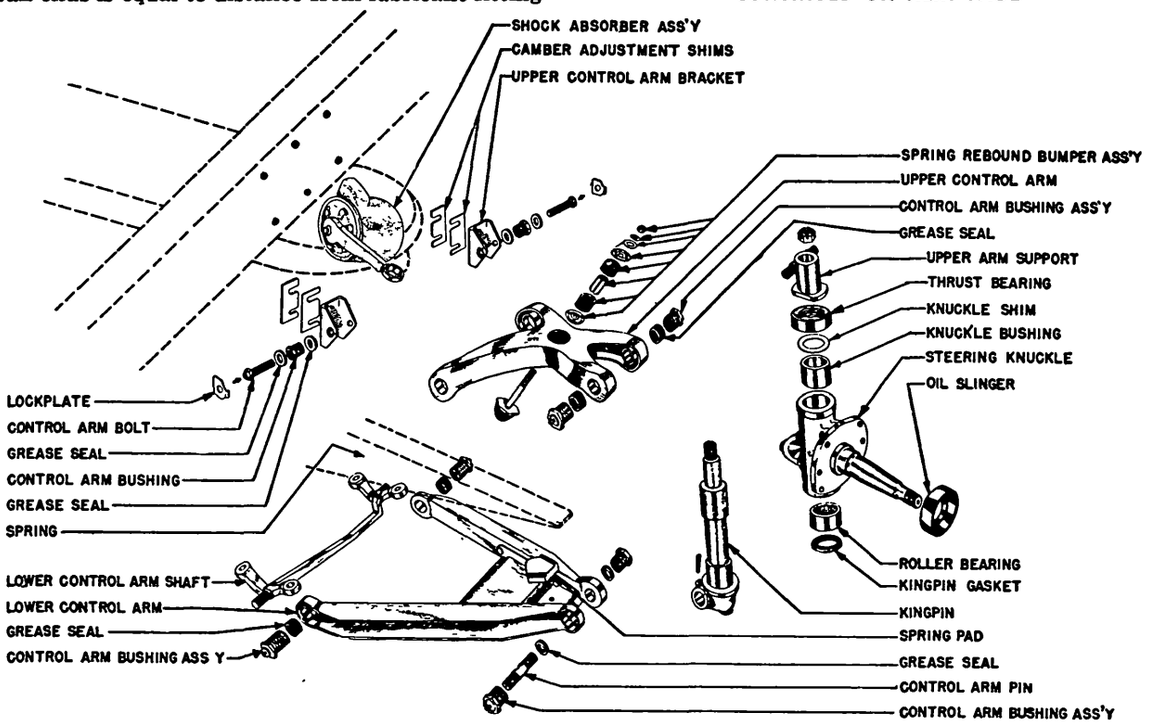
1). Left Hand Tie Rod Adjustment—Place steering wheel in straight-ahead position with cam lever studs on "high" points of cam, then line up left front wheel by stretching string between front and rear bumpers so that string contacts 1⅛" block (Champion), ½" block (Commander) placed against side of tire on rear wheel, adjust **left hand** tie rod so that front tire contacts string at front and rear of wheel, tighten tie rod clamp bolts. CAUTION—Do not disturb wheel position or this tie rod setting during remander of adjustment.

2). Center (Auxiliary) Tie Rod Adjustment—Adjust rod so that over-all length between centers of ball ends is equal to distance from lubricant fitting in auxiliary steering arm support to center of steering gear cam lever shaft (Champion), or to distance between lubricant fittings on the two steering bellcranks (Commander), tighten tie rod clamp bolts.

3). Toe-In (Right hand Tie Rod) Adjustment—Adjust right hand tie rod so that right wheel toed-in correct amount (1/16-⅛") with left wheel straight-ahead (see 1) above), tighten tie rod clamp bolts. CAUTION—On Champion, all tie rod clamp bolts must be positioned so that they are horizontal and below tie rods to prevent interference.

Right-hand Drive Car Note—Reverse above directions for toe-in adjustment on these cars (set right hand tie rod first, adjust toe-in at left hand tie rod).

►**1949 Adjustment Procedure:**



(1) Left Hand Tie Rod—Set steering wheel in center "straight-ahead" position with levers on high midpoints of cam. Adjust left hand tie rod so that left wheel points straight ahead.

(2) Right Hand Tie Rod—Adjust right hand tie rod to same length as left hand rod (on Champion, measure between ball stud centers at ends of rod; on Commander, measure between lubricant fittings on ends of rod).

(3) Center (Auxiliary) Tie Rod—Adjust toe-in by loosening clamp bolts and turning this center rod.

Steering Knuckle Stopscrew Setting—Adjust stopscrews for correct clearance with full right and left hand turns on each model as follows:
Champion—⅛" clearance between left hand back-

CONTINUED ON NEXT PAGE

1947-49 STUDEBAKER FRONT SUSPENSION

1947-49 STUDEBAKER (C nt.)

ing plate and control arms for full left turn, ⅛" clearance between steering gear arm and frame on full right turn.

Commander—⅛" clearance between backing plate and control arms for full right and left turns.

SPRINGS: Front spring is transverse leaf type with spring cover. Spring does not have conventional eyes (ends rest on spring pads on lower control arms). Removal and installation of spring requires special procedure and tools as follows:

Spring Removal: Raise front end of car, remove wheel and tire assembly, unhook outer end of one outer tie rod from steering arm. Place spring unloader puller plate (HM-925-19) across top outer end of front frame cross-member, attach puller arms and nuts (HM-925-17). Place guide plate center pad (HM-925-18) on underside of spring directly below puller plate, hook puller (HM-925) to puller arms. Tighten puller to compress spring until lower control arm relieved of spring pressure, take out four bolts in lower control arm inner shaft, swing control arm down out of the way. Remove six bolts mounting front spring plate on front frame cross-member. Relieve spring tension and remove puller. Slide spring out over opposite lower control arm inner shaft. Remove front spring plate from spring by taking off nuts on four U-bolts.

Spring Installation—Install spring by reversing removal directions above and note the following points: Tighten nuts on U-bolts just enough to hold spring plate in place on spring. With spring in place under car, align two holes in spring plate with two holes in cross-member nearest lower control arm which is assembled to cross-member (use two punches). Compress spring using puller assembly, install all six bolts mounting front spring plate on front cross-member. After connecting lower control arm and removing puller, and **with car weight on wheels, tighten the four U-bolt nuts to 75-80 ft. lbs. (Champion), 80-85 ft. lbs. (Commander).**

1950-55 STUDEBAKER

All Models (1950-55)

►CHANGES & CORRECTIONS

►*1955 CHUCKLING OR CRACKLING NOISE AT FRONT END CORRECTION:* Check lower support arm inner shaft attaching bolt nuts for tightness (black paint around inner shaft to crossmember contact area may be worn off or marked). Correct by removing the hug nuts one at a time. Place a hardened washer, Part No. 1539073 against the inner shaft boss and install new hug nuts. Tighten to 60-65 ft. lbs.

►*1955 SPEEDSTER MODEL FRONT SPRING SPACER PRODUCTION CHANGE:* Beginning with Car Serial No. 7166614, two spacers, Part No. 526830, are being installed on the left hand front spring as follows, to compensate for the greater load on that side. Install one spacer between front spring insulator and lower suspension arm. The other spring is installed between upper insulator and frame.

DESCRIPTION: Independent, parallelogram type with coil springs. Shock absorbers are direct acting type mounted within coil spring (except 1950 Commander—Rotary type).

►*1953 DESIGN CHANGE NOTE—Inner pivot shafts are mounted to upper and lower control arms with rubber type bushings. No lubrication required.*

CHECKING & ADJUSTMENT: First check (and adjust if necessary) front wheel bearings, steering gear, shock absorber action, steering arm and tie rod ends for looseness. Inflate tires to correct pressure. Place car on level floor when checking following specifications:

Tire Inflation: Different tires used on each model.
Champion (1950-55)—26 lbs. front, 24 lbs. rear.
Commander (1950)—24 lbs. front, 20 lbs. rear.
Commander (1951-53)—26 lbs. front, 22 lbs. rear.
Commander Exc. Sta. Wgn. (1954-55)—26 lbs. front, 22 lbs. rear.
Commander, Sta. Wgn. (1954-55)—26 lbs. front, 24 lbs. rear.
President (1955)—26 lbs. front, 22 lbs. rear.

Kingpin Inclination: 5¼° crosswise. Check camber if kingpin inclination not correct.

Caster: As indicated below: *CAUTION—Maximum variation between wheels must not exceed ¾°.*

Model	Caster
Champion (1950)	Neg. ½° ± ½°
Champion (1951)	Neg. 2° ± ½°
Commander (1950-51)	Neg. 2° ± ½°
All Models (1952-55)	Neg 1° to Neg. 2½°

Adjustment—Loosen clamp bolt in kingpin (knuckle support) at upper control arm pivot pin, remove lubrication fitting from front bushing of upper control arm outer pivot pin, insert Allen wrench through fitting hole and turn pivot pin until exact caster setting secured. Then adjust camber.

►*CAUTION—Camber will be disturbed by caster adjustment unless pivot pin rotated in complete turns only.*

Camber: 0° to Positive 1° (all models).

►*CAUTION—Manufacturer recommends ½° more camber on driver's side of car than on opposite side.*

Adjustment—After adjusting Caster (above), rotate pivot pin not more than ½ turn in either direction to secure correct camber. Recheck caster after camber adjusted (caster will be slightly changed but should be within limits specified).

►*CAUTION—Entire range of camber adjustment secured within ½ turn of pivot pin.*

Toe-In: 1/16/ to ⅛" (all models).

►*CAUTION—Tie rods must be adjusted in following order when making toe-in adjustment.*

(1) Left Hand Tie Rod (Wheel straight-ahead position). Turn steering wheel so that cam lever shaft is on "high" mid-point of cam (midway between end positions). If steering wheel spokes not horizontal in this position, remove and reposition wheel on shaft. Check left hand front wheel for straight ahead position by stretching string between front and rear bumpers on left side of car with 1 7/32" block (1950 Champion), ¾" block (1950 Commander), 1¼" block (All 1951 models) between sidewall of rear tire and string to compensate for difference in tread of rear wheel. If string does not contact tire sidewall at front and rear of front wheel, adjust left tie rod as required until wheel points straight ahead.

(2) Right Hand Tie Rod (Toe-In adjustment)—Without disturbing position of left hand wheel, check toe-in and adjust right tie rod for correct 1/16-1/8" toe-in.

►*RHD. CAR NOTE*—On right hand drive cars, reverse above instructions, setting right wheel in straight ahead position, and adjusting toe-in on left wheel.

Toe-Out on Turns: With outer wheel at 20°, inner wheel should be 23½°±1° (1950-54). With outer wheel at 20°, inner wheel should be 22½-23½° (1955). No adjustment. If incorrect, check for bent steering arm.

SHOCK ABSORBER REPLACEMENT: Can be removed and installed without disturbing other parts of front suspension system as follows:

All Models (Except Commander 1950): Remove lock and retaining nut at upper end of shock absorber. To prevent turning of shock absorber while removing, hold shock with wrench at small flats on end of shock absorber shaft. Remove grommet retainer, grommet and grommet seat. Remove two mounting plate retaining bolts, and thread the shock absorber out of spring.

►*CAUTION—There are no dust covers used on front shocks, therefore do not grasp exposed portion of shaft with tools, or mar the surface.*

Installation—Reverse removal procedure and note the following:

Retaining Nut Tightening—When properly tightened the retaining nuts should be flush with ends of threads on shaft.

Commander (1950): Remove shock absorber link nut at lower end of link arm (on inner side of frame side rail), free link from bolt and remove washers, rubber grommets, spacer, and grommet retainers (CAUTION—note location of these parts to insure re-installation in same order). Remove two bolts mounting shock absorber on end of upper control arm, remove shock absorber and cork grease seal. Install shock absorber in same manner.

COIL SPRING REPLACEMENT: To remove spring, raise front end of car and support it on jacks under frame side rails to rear of engine support cross-member. Place a hydraulic jack under mounting shaft at inner end of lower control arm. Disconnect stabilizer shaft at lower control arm, remove rubber bumper from arm (to prevent interference with

C NTINUED ON NEXT PAGE

1950-55 STUDEBAKER (Cont.)

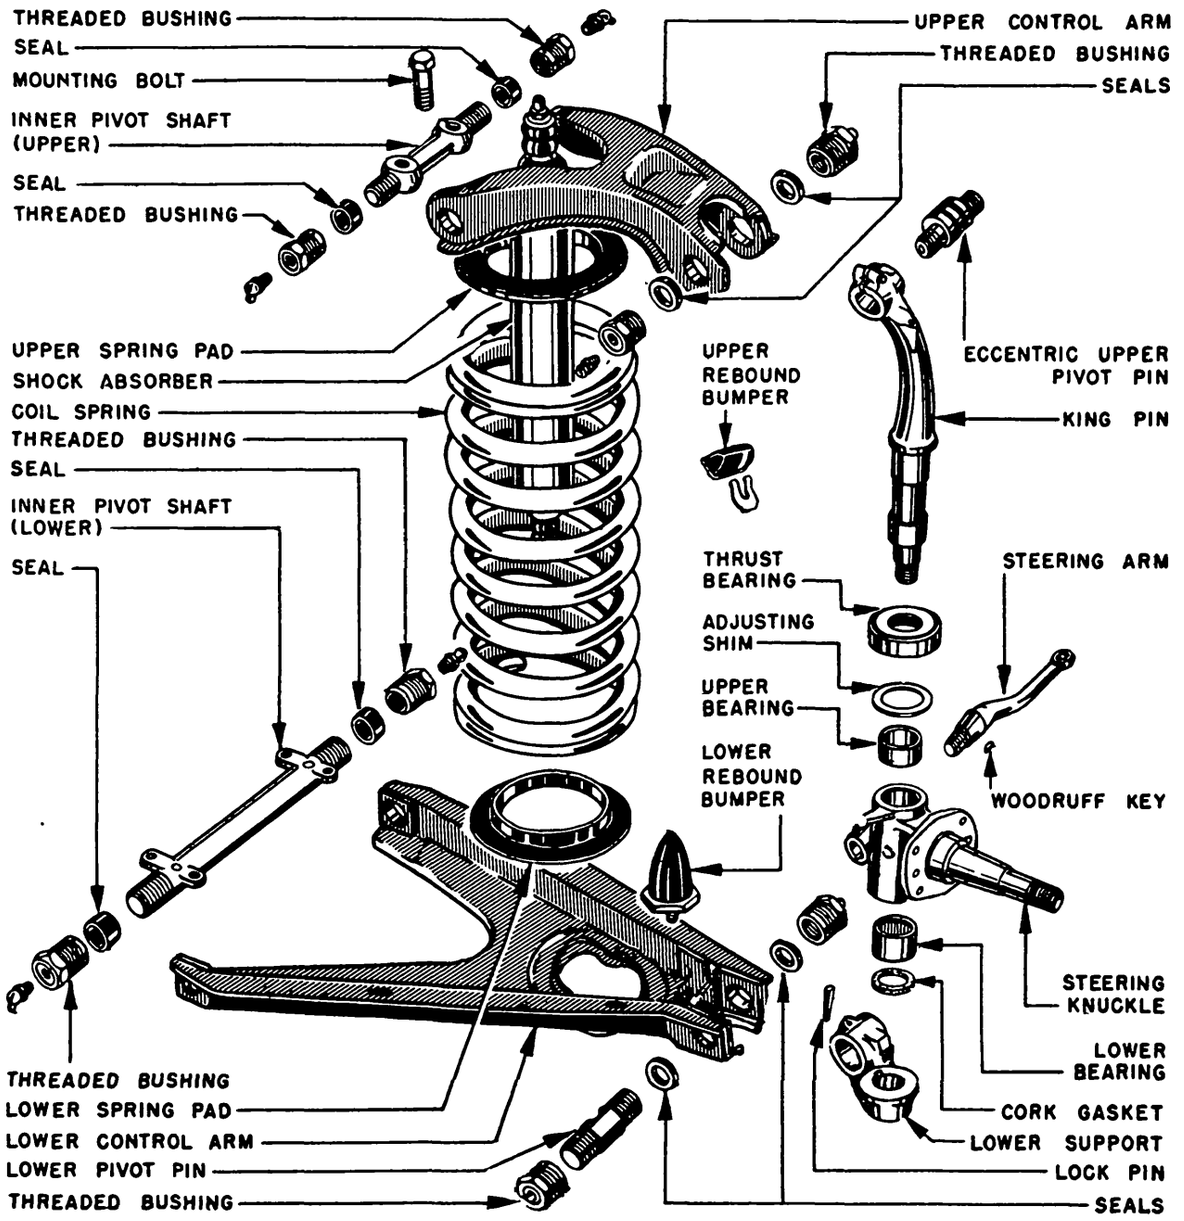
spring). Remove front shock absorber (except on 1950 Commander—see Shock Absorber Replacement above). **Take out four bolts mounting lower control arm shaft on cross-member (jack will hold arm in place), lower the jack until spring tension is relieved, remove jack, swing lower control arm out of the way, remove spring. Remove upper and lower spring pads.**

Installation—Be sure shock absorber mounting bolts are in place in control arm. Place lower spring pad on control arm seat. Position spring on upper spring seat. Hold spring so it remains seated and upper spring pad is not allowed to slip, then swing control arm inward seating the spring on control arm seat. Position pad of jack under inner shaft and slowly raise inner end of control arm and compress the spring. As the spring nears the cross-member, align holes of inner shaft and holes in flange of cross-member with a drift, then continue to lift inner shaft. With inner shaft held in position with jack, install the four retaining bolts and nuts and tighten securely.

LOWER CONTROL ARM REPLACEMENT: *NOTE*—1953 & Later Inner Pivot Shaft attached to control arm with rubber type bushings. Service procedures are different than on earlier types. See "1953 & Later Inner Pivot Shaft Removal & Installation" below.

Removal: Remove shock absorber and coil spring (see data above). Unscrew threaded bushings from outer end of control arm, drive out lockpin in lower support which locks pivot pin, then drive pivot pin out of support and lower control arm (CAUTION—use brass drift to avoid damaging pivot pin). Remove lower control arm and inner shaft assembly, clamp assembly in vise, unscrew inner shaft bushings, remove inner shaft and seals from arm.

Pivot Shaft Installation (1950-52 Models): Install new seal on each end of pivot shaft and position shaft in end of control arm. Use spreader tool J-2043 (1950), J-4677 (1951-52) installed on inner end of control arm to spread arm .015" (turn tool up finger tight, then turn ½ additional turn which will spread arms .015"). Hold shaft centered in arms and install bushings, tighten bushings to 170 ft. lbs. minimum torque. Remove tool and check to see that arm turns freely on shaft.



Pivot Pin Installation: Outer end of control arm must also be spread .015" when installing bushings (see Control Arm Reassembly following).

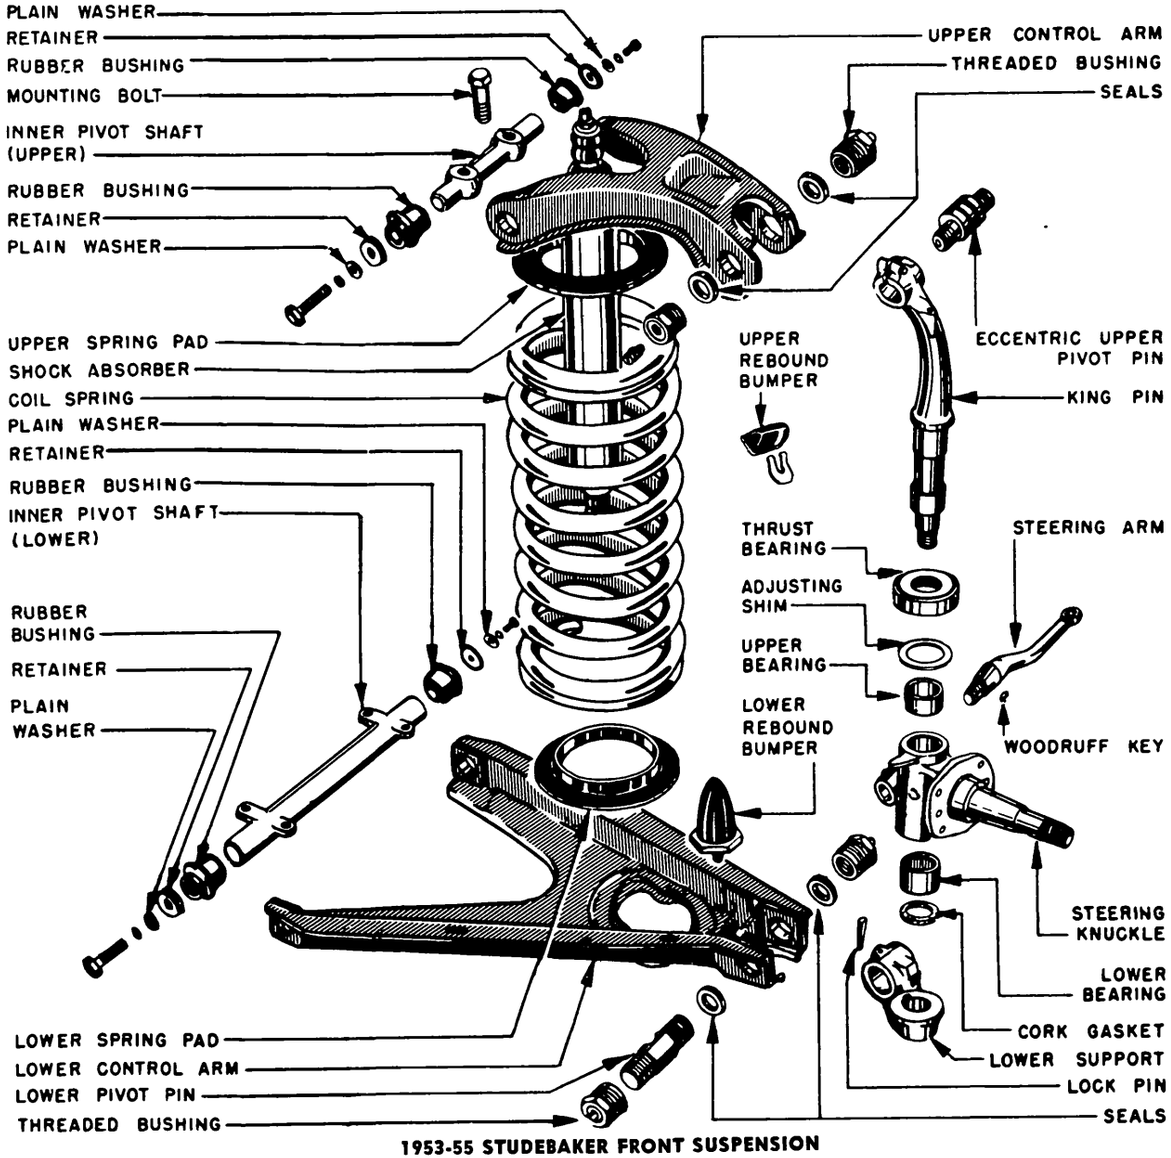
Reassembly & Installation: Establish desired dimension at outer end of control arm by measuring between outer faces of arm with calipers with .015" feeler placed between arm and one leg of calipers, lock calipers for use in checking arm after spreading. Position arm on lower end of knuckle support, install pivot pin in support with new seal on each end of pin, align slot in pin with lock pin hole in support (end of pin slotted for screwdriver blade), install lock pin. Use spreader tool J-2044 to spread outer end of arm until calipers just slip over arm without the .015" feeler gauge. Install bushings and tighten to 170 ft. lbs. minimum torque. Remove tool and check to see that arm turns freely on pin.

UPPER CONTROL ARM REPLACEMENT: *NOTE*—1953 & Later Inner Pivot Shaft attached to control arm with rubber type bushings. Service procedures are different than on earlier types. See "1953 & Later Inner Pivot Shaft Removal & Installation" below.

Removal: On 1950 Commander, disconnect shock absorber arm from frame bracket. Support car on jack under outer end of lower control arm. Remove wheel and tire. Unscrew both threaded bushings from outer end of control arm. On 1950 models, remove clamp bolt in upper end of knuckle support and remove pivot pin (not necessary on 1951-52 cars where arm can be maneuvered off over ends of pin). Mark top front end of inner pivot shaft to insure re-installation in same position, take out shaft mounting bolts and washers, lift control arm and shaft assembly off car. Clamp control arm in vise. On 1950 Commander, take out mounting bolts and remove shock absorber and cork gasket from arm.

CONTINUED ON NEXT PAGE

1950-52 STUDEBAKER FRONT SUSPENSION



1950-55 STUDEBAKER (Cont.)

On all models, unscrew both pivot shaft bushings, lift out pivot shaft and seals.

Pivot Shaft Installation (1950-52 Models): Install new seal on each end of pivot shaft and position shaft in control arm. Use spreader tool J-3957 (with adapter blocks J-3957-7 & J-3957-8 on 1951-52 cars). On 1950 cars, tighten tool hand tight, then turn hex. one complete turn additional to spread arm .090". On 1951-52 cars, tighten tool hand tight, then turn tool hex ⅓ (two flats) additional turn to spread arm .015". Hold shaft centered in arm with marked end in same relative position as originally, install both bushings, tighten bushings to 170 ft. lbs. minimum torque. Remove tool and make certain arm moves freely on shaft.

Pivot Pin Installation: Outer end of control arm must also be spread .015" when installing bushings (see Control Arm Reassembly following).

Reassembly & Installation: Install control arm and pivot shaft on frame making certain that shaft installed in exactly same position as originally (in accordance with marks made before removal). Spread outer end of control arm .015" using Spreader Tool J-2044 and calipers in same procedure as for lower control arm (see Lower Control Reassembly & Installation above). Insert pivot pin in upper end of knuckle support (hexagonal socket for adjusting wrench toward front of car) with new seal on each end of pin, align clamp bolt groove in pin with hole in support, install clamp bolt and tighten securely. Hold knuckle support centered in control arm, install bushings, tighten bushings securely to 170 ft. lbs. minimum torque. On 1950 Commander, install shock absorber making certain that cork gasket is in place, connect shock absorber arm link to frame bracket.

1953-55 STUDEBAKER FRONT SUSPENSION

1953 & Later Inner Pivot Shaft Removal & Installation (Rubber Type Bushings): Inner pivot shafts are mounted to control arms. No lubrication required.

Removal—Use Tool J-5472 to remove inner shaft control arm bushings, then remove inner shaft.

Pivot Shaft Installation (In Lower Control Arm): Insert one end of pivot shaft in member of control arm and push it as far as possible into member so opposite end of shaft can be swung into position and inserted in other member of control arm. Place J-5472-6 (Large Spacer) in position between ends of control arm. Start rubber bushings in holes at either end of control arm, then place J-5472-1 (Large Installer) in position on each bushing and, using an arbor press, force bushings into place until shoulder on outer sleeve of bushing is seated against control arm *(CAUTION*—Do not attempt to seat flange of bushing on control arm). Install bushing cap, flat washer, lockwasher, and capscrew. After control arm has been installed in car and with weight of car on springs, tighten the capscrews to 65 ft. lbs.

Pivot Shaft Installation (In Upper Control Arm): Insert one end of pivot shaft in member of the control arm and push it as far as possible into member so opposite end of shaft can be swung into position and inserted in other member of control arm. Place J-5472-5 (Small Spacer) in position between ends of control arm. Start rubber bushings in holes at either end of control arm then place J-5472-2 (Small Installer) in position on each bushing and, using an arbor press, force bushings into place until shoulder on outer sleeve of bushing is seated against control arm *(CAUTION*—Do not attempt to seat flange of bushing on control arm). Install bushing cap, flat washer, lockwasher, and capscrew. After control arm has been installed in car and with weight of car on springs, tighten the capscrews to 35 ft. lbs.

SPRINGS: Springs are installed with rubber pad in spring seat recess in front cross-member (upper) and lower control arm (lower).

►CHANGES, CAUTIONS, CORRECTIONS

►**SPRING MOUNTING PRODUCTION CHANGE (4-63 & 6-63):** Effective Serial No 65974 (4-63) and Serial No. 12098 (6-63) front spring clip plate changed. Parallel plate and two spring clip plates were added. Clip plates fit over ends of "U" bolts and are held in place by the downward projecting edges of parallel plate preventing side movement of spring and any change in camber.

►**REPLACEMENT SPRING CAUTION (4-63 & 6-63):** Manufacturer recommends that whenever front spring replacement required, special **Heavy Duty Spring** be installed on assumption that car is subjected to overloads or operated on rough roads. When these springs installed, other parts should also be installed as follows:

Replacement Spring Parts

Heavy Duty (Export) Front Spring	No. 646855
Spring Clip (2 required)	No. 646813
Spring Bumper (2 required)	No. 645763
Spring Clip Plate (2 required)	No. 641020
Front Shock Absorber	See Note

►**TOE-IN CAUTIONS TO PREVENT UNDUE TIRE WEAR:** Excessive tire wear may be caused by incorrect toe-in due to following causes:

Bent Tie-Rods—May be caused by tie rods contacting rails of "free-wheel type" lift and weight of wheels hanging on tie rods in this position.

CAUTION—Wheels should be blocked up when car raised on this type lift.

Incorrect Toe-In Adjustment Procedure—Toe-in changes with load and must be set exactly as specified under Toe-in below.

►**KNUCKLE SUPPORT INSTALLATION CAUTION:** on right & left side similar in appearance but must **not be interchanged** (results in wrong camber causing unstable steering). These parts marked for identification as follows:

Left Knuckle Support—Has part number—641026 (early cars) or letter "L" stamped on front face at center (later cars).

Right Knuckle Support—Has part number—641027 (early cars) or letter "R" stamped on front face at center (later cars).

DESCRIPTION: Planadyne independent suspension **with transverse spring serving as lower control arm (spring is "Dow" type with second leaf wrapped around spring eye in main leaf for safety). Short upper control arm is mounted at frame end on rubber bushings (movement of arm on frame bracket shaft permitted by flexing of rubber bushings). Direct acting type shock absorber is linked to spring pivot pin (lower end) and special mounting stud at midpoint of upper control arm (upper end).**

CHECKING & ADJUSTMENT: Check front wheel bearing adjustment, tire inflation pressure, steering gear adjustment, shock absorber action, and steering linkage for correct adjustment and freedom of movement first, then check front suspension system as follows:

Tire Inflation: Check and inflate each size tire as follows:
(6.00x15 & 6.50x15)—24 lbs. frt., 28 lbs. rear.
(6.70-15)—20 lbs. front, 24 lbs. rear.

Kingpin Inclination: 5° crosswise.

Caster: 1°. No adjustment (determined by design of front suspension units—correct by replacing necessary parts).

Camber: 1¼-1¾° (4-63, 6-63), 1° (Others). Controlled by shims under each control arm mounting bracket.

►*CAUTION*—Number and thickness of shims under both brackets on same side of car must be equal.

To Adjust—Loosen upper control arm frame bracket mounting screws, remove shims from between bracket and frame (to decrease camber), add shims (to increase camber) **equally at each bracket.** Shims are furnished in thicknesses of .060" and .120" and are slotted to facilitate adjustment (bolts need not be completely removed).

Toe-In: 1/16-1/8" at curb weight (car ready for road with full tank of fuel and spare tire, but without load)

►*CAUTION—Toe-in varies slightly with load and should be checked and adjusted exactly as follows:*

To Check Toe-In: Jack up front wheels, chalk center of tread over entire circumference of both front tires, use pencil to scribe a line at exact center of tread over entire circumference of tires (hold pencil on steady rest while rotating tire). Turn wheels to straight ahead position with steering gear on high midpoint of cam and steering wheel spoke parallel to windshield, lower car so that weight rests on wheels and load or weight down the front end of the car so that the **front spring main leaf is flat** (measure with straightedge below leaf). Roll car forward and backward to allow all parts to assume natural position. Check distance between marks on tires at front and rear of wheels and adjust to ZERO TOE-IN (equal distances at front and rear) under these conditions. NOTE—With toe-in set at ZERO under above loading conditions, toe-in will be 1/16" to 1/8" when load removed (dependent on arch of front spring).

To Adjust Toe-In: Loosen clamps on adjusting sleeve on each tie rod and turn adjusting sleeves on **both tie rods equally** when setting toe-in.

SPRINGS: ***CAUTION—See "Replacement Spring Caution" above for recommended replacement spring and other changes necessary when this spring installed.***

Standard Spring—"Dow" type with rubber inserts in forged cups at ends of spring leaves (spring movement flexes these rubber inserts).

Heavy Duty (Export) Springs—Not "Dow" type (no rubber inserts) but spring assembled with graphited compound between spring leaves. Both first and second leaves are wrapped around spring eyes for greater safety, and four additional clips are used to distribute rebound stress of main leaf throughout spring. NOTE—This spring is recommended as replacement for standard spring above.

SUSPENSION ASSEMBLY: When disassembling suspension system for renewal of parts, assemble as follows:

Upper Support Arm & Knuckle Support: Upper support arm is mounted on rubber bushings at inner (frame) end and on pivot bolt threaded through eyes in arm and in bushing in knuckle support at outer end.

Frame Support Bushings—Install bushing half in each side of frame bracket, install plain washer, lockwasher, and nut on support arm bar, tighten nut securely (shoulder on bar limits compression of rubber bushings).

Knuckle Support Pivot Bolt—Install threaded bushing in support with head toward front, tighten bushing to 175 ft. lbs. Place rubber seal on each end of bushing, hold knuckle support centered in end of support arm and thread pivot bolt in from front through support arm eye and knuckle support bushing, install nut on rear end of bolt

Knuckle Support & Spring Pivot Bolt: When installing support on car, hold support centered on spring eye while installing pivot bolt.

►***CAUTION—Knuckle support must be centered on spring (at bottom) and on support arm (at top) to insure correct Caster specification.***

1952-55 WILLYS PASSENGER CARS

All Models (1952-55)

▷CHANGES & CORRECTIONS

▷*1954 DESIGN CHANGES:* On 1954 & Later front suspensions the thickness of the lower pivot shaft and steering knuckle support are increased. Lower control arm trunnion was modified to provide a straight through trunnion bolt. Distance from center of upper trunnion bolt to center of lower trunnion bolt was changed from 10¾" to 11 5/16". The capacity of the front shock absorbers was increased and its position and action reversed. Front coil spring free length was increased from 17½" to 18½". Parts are not interchangeable with earlier type parts unless entire suspension assembly (both sides of car) is changed.

▷*1955 6-226 SPINDLE & TRUNNION KIT (To Insure Correct Thread Fit):* Kit, Part No. 910936, has been released. Kit consists of one spindle support, one upper and one lower trunnion, thread fits of which have been selectively fitted.

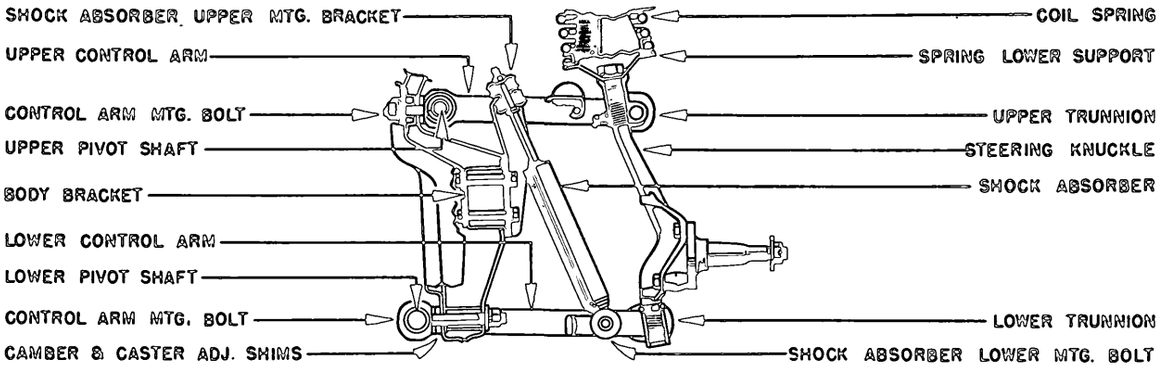
▷*1953 FRONT SUSPENSION PRODUCTION CHANGE:* A new cross-member, connecting right and left front suspension assemblies is used on later cars. Cross-member Kit, Part No. 809562 is available for installation on earlier cars.

▷*1953 LOWER CONTROL ARM TRUNNION PRODUCTION CHANGE:* Trunnion (0°), Part No. 806651 supersedes the previous trunnion Part No. 803215. When replacement is necessary, replace both trunnions with the later type. Reset camber and caster when new type trunnions are installed.

▷*1953 NOISY TRUNNION CORRECTION*—May be caused by overtightening bolt and nut holding lower end of shock absorber. To correct, loosen nut, then work suspension up and down until bind works free. Torque tighten nut to 50-55 ft. lbs. If noise persists, place .005" spacer washer on bolt between shock absorber bushing spacer and control arm yoke. Tighten nut to 50-55 ft. lbs. torque.

DESCRIPTION: Independent linked parallelogram, with new type coil spring mounting, and direct acting shock absorbers.

Shock Absorber—(1952-53) Upper end mounted on bracket on frame member, lower end connected to lower control arm. (1954 & Later) Upper end connected to upper control arm, lower end mounted on bracket on frame member.



CHECKING & ADJUSTING: Before making adjustments to front suspension system, check wheel bearing adjustment, steering gear adjustment, tire inflation pressure, wheel balance and tire run-out, then place car on level floor and check following specifications:

Kingpin Inclination: (1952-53) 8° crosswise. (1954 & Later) 6° crosswise.

Camber: (1952-53) Pos. 1° ± ¼°. (1954 & Later) Pos. ¾° to Pos. 1¼°.

Adjustment—Adjusting shims are located between lower control arm shaft eye bolts and frame, and camber adjustment is made by adding or removing an equal amount of shims at this point on both front and rear eye bolts—⅛" shims equal to ½°, 1/16" shims equal to ¼° of camber.

▷*SHIM NOTE—Caster will be affected if shims are not removed or replaced in equal thicknesses on the two eye bolts.*

1952-53 WILLYS PASS. CAR FRONT SUSPENSION

Caster: (1952-53) Pos. 1° ± ½°. (1954 & Later) Pos. ½° to Pos. 1½°.

Adjustment—Adjusting shims are located in same place as camber shims (above). Adding shims to the front mounting eye bolt provides Positive Caster. Adding shims to rear mounting bolt provides Negative caster.

ADJUSTMENT NOTE—It is recommended that caster adjustment be set to high limit.

Toe-In: 3/32" to 5/32".

Adjustment—With wheels set in a straight ahead position, and car at curb weight, loosen adjusting sleeve clampscrews on both adjusting sleeves and turn adjusting sleeves equally to get desired adjustment.

COIL SPRING REPLACEMENT (Removal): Disconnect brake line at wheel, and remove wheel, hub and drum as an assembly. Install the pair of spring clamps Tool W-235 on the coil spring (clamps opposite each other) and screw up on each clamp evenly until coil spring is compressed sufficiently for removal. Place jack under side of body and raise sufficiently to remove the spring from body and lower spring support. Install spring compressor Tool W-235 in spring and tighten enough to free spring clamps. Remove clamps and unscrew spring compressor.

Installation—Compress the coil spring with spring compressor Tool W-235 to a suitable length to install the spring clamps, then remove the compressor tool. Align the front spring lower support in control arm with spring well in wheelhouse, and install spring. Make sure that spring does not distort or bow.

SHOCK ABSORBER REPLACEMENT: On 1952-53 Models remove nut from top of shock absorber stem above bracket and remove rubber insulating pad. Push shock absorber stem down through bracket and free. Remove lower shock mounting bolt in lower control arm and remove shock absorber. On 1954 & Later Models remove nuts and bolts and each end of shock, then remove shock absorber. To install, reverse removal procedure. *NOTE*—On 1952-53 Models shock absorber stem is smoothly machined to work through tight seal in upper end of piston. Do not roughen stem with pliers or similar tools. Lubricate lower shock absorber bushing with liquid soap to facilitate installation of bolt.

CONTROL ARM ASSEMBLY REMOVAL: Upper control arm, lower control arm, shock absorber, and steering knuckle support is removed as an assembly, by removing coil spring (see above), and then remove nuts securing upper and lower control arms to frame brackets. *CAUTION*—Remove shims from lower control arm eye bolts, noting their thickness and position. These shims control camber and caster, and must be reinstalled in their respective positions when control arms are reassembled.

▷*NOTE:* On 1954 & Later Models crossmember must be removed before control arms can be removed.

Reassembly—Install trunnion in upper and lower control arms. Trunnion must be centered accurately by using a feeler gauge inserted between trunnion and control arm (push rubber seal aside). Make sure trunnion does not bind at any point and then tighten nuts securely against lockwashers. To install pivot shafts, Special Tools W-232 (upper Control Arm), and W-233 (Lower Control Arm) must be used to avoid distortion of control arms and for correct spacing of pivot shaft. Place control arm in vise with pivot shaft end upward. Install pivot shaft assembly and rubber seals (install seals on pivot shaft using liquid soap) in control arm and install special tool (see above) between ends of control arm pivot shaft and control arm. Install end bushing bolts and tighten to 65-80 ft.lbs. torque. Screw steering knuckle support into lower control arm trunnion until rubber bushing is positioned to seal the joint. *Do not screw support into trunnion enough to distort the bushing.* Install steering knuckle arm, and brake backing plate, then screw the upper trunnion on steering knuckle support until the distance from center of grease fitting in upper control arm to center of grease fitting in lower control arm is 10¾" (1952-53), 11 15/16" (1954 & Later). Attach spring lower support to upper control arm trunnion.

Installation—Reverse the removal procedure outlined above and install the same number and size shims on the same bolts from which they were removed. Install coil springs (see above) and check front suspension alignment.

SPRINGS: Free Length—(1952-53) 17½". (1954 & Later) 18½".

STEERING LINKAGE (MANUAL STEERING GEARS)

►CHANGES, CAUTIONS, CORRECTIONS

►*1954 NASH "RAMBLER" STEERING LINKAGE INTERFERENCE CORRECTION & PRODUCTION CHANGE:* To eliminate steering linkage interference, all "Rambler" Series cars after Serial No. D-179972, and prior to D-181012 (with Idler Arm No. 3116777), MUST HAVE THE IDLER ARM SPACER, Part No. 3140214, installed on idler arm bushing between head of bushing and the idler arm. Effective at "Rambler" Serial No. D-189717, the Idler Arm (Part No. 3117263), has been revised, eliminating need for above spacer.

►*1954 NASH IDLER ARM "RATTLE" CORRECTION:* To correct rattles proceed as follows: **1) Steering Linkage Ball S at**—Loosen adjusting plug several turns, retighten until it is up solid, then loosen plug to first cotter pin hole but not more than 90° maximum. **2) Ti Rod Ball Stud**—Center in opening of cross tube with tie rod square with steering arm by loosening one of clamps on adjusting tube and rotating tie rod to a position where stud will not contact side of cross tube opening (This practice should always be followed when adjusting toe-in). **3) Steering Worm & Cr ss Shaft**—Should be adjusted if there is evidence of clearance while wheels are in straight-ahead position on worm "high point". **4) Front Wheel B arings**—Adjust for minimum clearance by tightening until there is a slight drag noted, then loosen to first castellation. *(NOTE*—Looseness in wheel bearings can be felt by shaking wheel vertically—top and bottom).

►*1954-55 OLDSMOBILE STEERING TIE-ROD STRIKING OIL PAN CORRECTION:* To prevent tie-rod from striking oil pan on extreme turns, place a 7/16" flat washer under head of wheel stop bolt on steering knuckle support so that stop bolt protrudes a minimum of 1". If this does not provide at least 1/8" clearance between tie-rod and pan, reform pan slightly as necessary. *CAUTION* - Be careful not to puncture oil pan.

►*1955 F-100 & 250 FORD TRUCK DRAG LINK INSTALLATION CAUTION:* Due to design of drag link (THAA-3305-A), it is possible to install drag link in reverse position, causing steering interference. When properly installed, offset end of drag link is attached to sector shaft arm, and lubrication fitting will be at bottom side of link.

STEERING LINKAGE & ADJUSTMENT: Special linkage and adjustment on cars and trucks as follows:

1946-53 BUICK

Buick: Linkag - Direct center point steering type. Long right hand tie rod is located between steering arm and right wheel. Short left hand rod is located between other tie rod and left wheel. Right tie rod is joined to left tie rod and to pitman arm by a ball stud and spring-loaded bearing connections.

Toe-In Adjustm nt (1946-49) - Loosen clamp bolts. To increase toe-in, turn adjusting sleeves in same direction as wheels rotate when moving forward; to decrease toe-in, turn sleeves in opposite direction. *CAUTION*—Both sleeves must be turned *qual am unts in sam dir ction* in order not to disturb straight-ahead wheel position. After adjustment completed make sure tie rod clamps are within 1/8" of end rods and that ear of clamp overlaps slot in tube not less than 1/16".

Toe-In Adjustment (1950-53) - Loosen clamp bolts, then proceed as follows:

Series 40 & 50 - *Decrease* toe-in by turning *left* sleeve in same direction as wheel rotates moving forward and turn *right* sleeve in opposite direction. Increase toe-in by turning both sleeves in opposite direction.

Series 70 - *Increase* toe-in by turning *left* sleeve in same direction as wheel rotates moving forward and turn *right* sleeve in opposite direction. Decrease toe-in by turning both sleeves in opposite direction.

►*CAUTION* - Left and right adjusting sleeves must be turned exactly the *same amount but in opposite directions* in order to maintain front wheel straight-ahead position. On Series 70, make sure that tie rod clamps are within 1/8" of end of rods and that ear of clamp overlaps slot in tube not less than 1/16".

Tie Rod Plug Adjustment - Turn tie rod plug up solid, then back off two turns and install cotter pin.

1954-55 BUICK

Buick: Linkage—Consists of an intermediate rod between steering gear pitman arm and idler lever on right side of frame, and individual tie rods between intermediate rod and each wheel. Adjustable sleeves provided at end of each tie rod for toe-in adjustment.

Toe-In Adjustment—Turn steering wheel until lower spoke is vertical, with front wheels in straight-ahead position. Measure horizontal distance from near edge of front boss of lower control arm shaft to front edge of brake backing plate, on each side. Adjust tie rods, if necessary, to make measurements equal on both sides. To adjust toe-in, loosen clamp bolts and turn adjusting sleeves at tie rod ends as required. Decrease toe-in by turning left sleeve in same direction as wheel rotation when moving forward and turn right sleeve in opposite direction. To increase toe-in reverse direction of sleeve movement given above. *CAUTION*—Right and left sleeves must be turned equal amounts but in opposite directions when changing toe-in, in order not to disturb straight-ahead position of front wheels. Before tightening sleeve clamps, have slots in sleeve and clamps aligned.

Idler Lever & Support Adjustment—In order that idler lever ball stud is kept level with pitman arm ball stud, thread support into idler arm bushing until distance from center of support lower bolt hole to nearest face of idler lever is 2 21/32" to 2 3/4".

Intermediate Rod End Plug Adjustment—On idler lever end of rod, turn end plug up tight then back off 1/4-1/2 turn (1/2 turn preferred) and install cotter pin. On pitman arm end of rod, tighten end plug to 20-25 ft. lbs. torque, then back off 1 7/8—2 1/8 turns and install cotter pin.

1950-55 CADILLAC

Cadillac: Linkage—Consists of a drag link between steering gear pitman arm and idler arm mounted on right frame side rail, and individual tie rods between drag link and each wheel. Adjustable sleeves provided at outside ends of tie rods for toe-in adjustment.

Toe-In Adjustment—Loosen clamp screws on adjusting sleeves. Turning adjusting sleeves in direction of forward wheel rotation decreases toe-in. Turn sleeves equal amounts so that relation of steering gear high spot to straight-ahead position of front wheels will not be changed. When tightening clamp screws, be sure open side of clamp is over open side of adjusting sleeve.

Drag Link Adjustment—Place straight bar across two adjustable jacks, directly below drag link. Adjust height of jacks so that distance from top of bar to flat spot on frame is equal on both sides (Adjusting jacks to even number of inches will facilitate measurements). Measure distance from top of bar to bottom of drag link on both sides. Difference in measurement between 1st measurement (top of bar to flat spot on frame) and 2nd measurement (top of bar to bottom of drag link) should be 4-5/16" (1950-53), 4-7/8" (1954-55) and equal at both ends of drag link within 1/8" (MEASURE TO SEE THAT DRAG LINK IS PARALLEL TO FRAME WITHIN 1/8"). If idler arm end of drag link not within limits, remove idler arm support mounting screws on frame side bar, and screw idler arm in or out of bushing until correct height obtained. *(CAUTION*—When turning idler arm into bushing to raise drag link, be sure idler arm is at least 1/2 turn off base to prevent interference on turns. When turning idler arm out of bushing, do not unscrew more than 2 1/2 turns from base or excessive play will result). If proper height cannot be obtained with this adjustment, replace idler arm. If pitman arm end of drag link is not within limits, pitman arm must be removed and bent as required.

Drag Link Plug Adjustments—Install end plug in pitman arm end of drag link and adjust by turning down tight and backing plug off 1/2 to 5/8 turn. Install cotter pin. Install right end plug and adjust by turning down tight and backing off 1/4 to 1/2 turn. Install cotter pin.

Idler Arm Support Adjustment—Turn idler arm support with seal into idler arm bushing until it bottoms, and then back off 1/2 to 1 1/2 turns.

1949-54 CHEVROLET PASS. CARS

Chevrolet Passenger Cars: Linkage—Consists of steering idler and third arm mounted on frame cross member and linked to each front wheel by separate tie rods (adjustable rod on left side, non-adjustable rod on right side). Idler arm is linked to steering gear pitman arm by steering connecting rod (adjustable for length to enable maintaining high point of steering gear adjustment with front wheels straight-ahead).

Toe-In Adjustment—Loosen clamp bolts at each end of left hand tie rod and turn rod to increase or decrease its length as necessary, until proper toe-in is secured. Before locking clamp bolts, make sure tie rod ends are in alignment with their ball studs.

St ring C nn cting R d Adjustm nt—If wheels not in straight-ahead position with steering gear on high point, set front wheels in straight-ahead position

CONTINUED ON NEXT PAGE

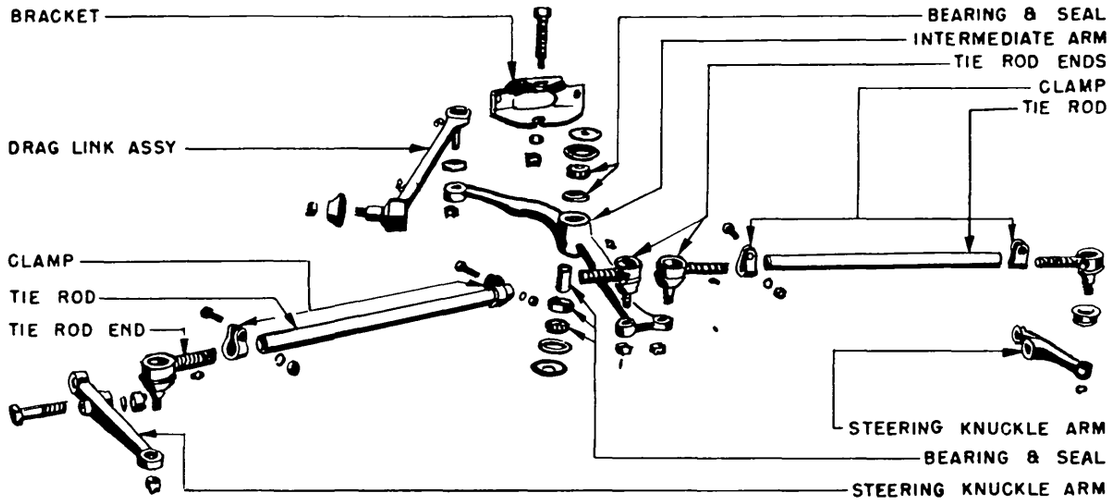
(MANUAL STEERING GEARS) (Continued)

(can be checked by measuring distance between lubrication fitting on lower control arm shaft and the wheel fellow on each side). Remove ornamental cap or horn button and check position of mark on end of worm shaft designating gear high point (mark should be at top of shaft). If gear has been moved off high point when setting wheels in straight-ahead position, loosen steering connecting rod adjuster clamps and adjust as necessary to bring gear back on high point.

Idler & Third Arm Pivot Pin Bushings Replacement–Drive out old bushings using K-318 steering knuckle bushing driver. Press new bushings in bracket using Tool K-318. Ream bushings to .922- 923" using J-3189 bushing reamer.

Idler & Third Arm Clearance Adjustment–If clearance between idler and third arm and bracket exceeds .006", when measured with a feeler gauge, install shim, Part No. 3687657, between bracket and lower face of idler and third arm assembly. If clearance between front suspension cross member and bracket at upper mounting hole exceeds .008", when measured with feeler gauge, add shims as necessary to bring space within allowable limits (.010" shims available).

1955 CHEVROLET PASS. CARS



Chevrolet Passenger Cars: Linkage–Consists of steering connecting rod between pitman arm and idler arm, bracketed on right frame side rail, and individual adjustable tie rods between steering connecting rod and each front wheel. Tie rods have adjusting sleeves at outer ends for making toe-in adjustment

Toe-In Adjustment–Set steering gear on high point of worm, with mark on top end of steering mainshaft in vertical position and steering wheel positioned for straight ahead driving Loosen clamp bolt at each end of each tie rod and adjust them individually for desired toe-in Position tie-rod clamp bosses below the tie rod to avoid frame interference,

Steering Wheel Alignment & High Point Centering - Remove steering wheel ornamental cap or horn button and wheel retaining nut. Set front wheels in straight-ahead position. Check position of mark on end of worm-shaft designating steering gear high point (Mark should be at top of shaft and aligned with mark on steering wheel). Remove steering wheel, if necessary, and align mark on wheel with mark on end of wormshaft. If gear has been moved off high point when setting wheels in straight-ahead position, loosen adjusting sleeve clamps on both right and left hand tie rods, then turn each sleeve an **equal amount in same direction** to bring gear back on high point.

1948-55 CHEVROLET TRUCKS

Chevrolet Trucks: Linkage–Consists of three-piece tie rod (rod and two tie rod end assemblies) between front wheels. Tie rod end assemblies have right and left hand threads to facilitate toe-in adjustment. A connecting rod, between steering third arm (on left wheel) and pitman arm, has permanently installed studs in ends. Ends of studs are threaded and are attached to steering third arm and pitman arm with a nut and cotter pin.

1946-54 CHRYSLER & DESOTO STEERING LINKAGE

Toe-In Adjustment–Loosen clamp at each end of tie rod and turn tie rod to increase or decrease its length until proper toe-in is secured. Before locking clamps, be sure tie rod ends are in alignment with studs.

1946-54 CHRYSLER & DESOTO

Chrysler & DeSoto: Linkage–Consists of steering gear intermediate arm mounted on frame cross member which transmits motion from steering gear, through drag link, to each front wheel, through independent tie rods. Both tie rods are adjustable.

Toe-In Adjustment–Loosen clamps on ends of tie rods. Adjust both tie rods equally. Lengths of tie rods should be equal after adjustment to insure correct steering gear position (intermediate arm should be on center-line of car when wheels are in straight-ahead position). When threading tie rod ends into tie rod, thread ends evenly to have a tie rod nominal length of 23" (center to center). *NOTE*–Steering wheel hub, gear arm, tube and steering gear roller shaft are machined with master serrations to place wheels in straight-ahead position when steering wheel is in center position. No attempt should be made to change relative position of these parts by altering master serrations. Improper positioning of steering wheel should be corrected only by adjusting tie rods. Make certain clamping bolts on bottom of tie rods, then tightened.

Drag Link Installation–Whenever drag link removed, care must be taken to insure proper reinstallation in order to provide clearance on extreme turns. It will be noted that one end of drag link is offset slightly, while other end is straight. Offset end should be connected to steering gear arm. On most cars, the drag link is marked "Rear" on the ball retainer expansion plug at rear end to insure proper installation.

Intermediate Arm Bearing Adjustment–Insert sufficient number of shims between upper bearing race and arm spacer so that when assembly is clamped in vise, arm can be rotated with a pull of approximately 1 lb. at end of arm (drag link end).

1946-55 DODGE 6 & PLYMOUTH 6

Dodge 6 & Plymouth 6: Linkag –Consists of long and short tie rods (both adjustable) attached directly to steering gear arm

Toe-In Adjustment–Place front wheels in a straight-ahead position, loosen clamps on ends of tie rods, adjust tie rods an equal amount in opposite directions until desired toe-in is obtained. If steering wheel center spoke does not point straight downward, adjust both tie rods an equal amount in same direction until steering wheel centered. When adjustment correct, pivot ends of tie rods on ball studs so they are both against front or back sides of studs, then tighten clamp bolts with clamping bolt on left end of long tie rod beneath tie rod to prevent interference on turns. *NOTE*–Steering wheel hub, steering gear arm, steering tube and steering gear sector shaft are machined with master serrations for a definite location. No attempt should be made to change relative position of these parts by altering master serrations. Improper positioning of steering wheel should be corrected only by adjustment of tie rods.

1955 CHRYSLER, DESOTO & PLYMOUTH 8 1954-55 DODGE V8

Chrysler, DeSoto, Dodge V8, Plym uth V8: Linkage–Consists of idler arm bracketed to right frame side side member and connected to right end of drag link Pitman arm is connected to left end of drag link Individual tie rods, connected to drag link near its center, have sleeve adjustment for toe-in at outside ends

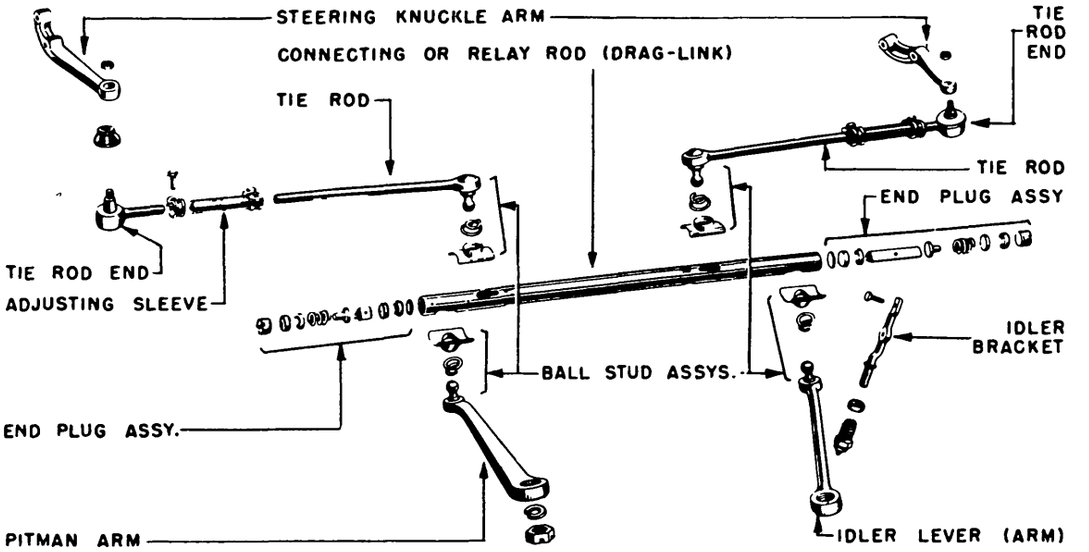
Toe-In Adjustment–Loosen clamp bolts at each end of adjusting sleeves. Ends should be threaded evenly into tube sleeves to have a nominal length (center to center) of 21-3/8". When tightening sleeve clamps, make sure bolts are beneath tie rods to prevent interference on turns. *NOTE*–Steering wheel hub, steer-

CONTINUED ON NEXT PAGE

(MANUAL STEERING GEARS) (Continued)

ing gear arm, steering tube and steering gear sector shaft are machined with master serrations for a definite location. No attempt should be made to change relative position of these parts by altering master serrations. Improper steering wheel positioning should be corrected only by adjustment of tie rods.

Idler Arm Clearance Adjustment–Screw idler arm support bracket into bushing until it bottoms. Then back off approximately one full turn of idler arm or, until a clearance of 1 7/16" plus or minus 1/16" has been obtained between shoulder of bracket and flat surface of arm.



Idler Arm Bushing Replacement–If idler arm bushing play exceeds 1/8" when idler arm is moved up or down or, if noise has developed in steering linkage a new idler arm bushing, support bracket or both should be installed as follows: Remove cotter pin, nut and spacer that holds drag link end ball stud to idler arm. Insert pry bar between idler arm and drag link. Jar drag link ball stud loose by driving on end of link. Separate link and arm, then remove seal. Remove two bolts and lockwashers that attach idler arm support bracket to frame side rail. Remove support bracket, idler arm and bushing as a unit. Unscrew idler arm support bracket from idler arm bushing, then remove seal. Clamp end of idler arm bushing in a vise and remove locknut. Now, unscrew idler arm from bushing. (NOTE–Before removing idler arm from bushing, mark flat of arm to indicate up or down side. Arm has tapered hole for ball stud and can only be installed in one position). To install, reverse removal procedure, noting "Idler Arm Clearance Adjustment" above. If straight fitting (lubrication) found on end of bushing, replace with a 60° or 90° fitting for ease in lubrication.

1952-55 FORD PASS CARS

Ford Passenger Cars: Linkage–Consists of steering arm-to-idler arm rod which transmits motion from steering gear through steering arm, attached to left end of steering arm-to-idler arm rod, to front wheels through spindle connecting rods (tie rods). Spindle connecting rods have adjustable sleeves on outside ends for toe-in adjustment. Idler arm attached to right frame side rail and to right end of steering arm-to-idler arm rod.

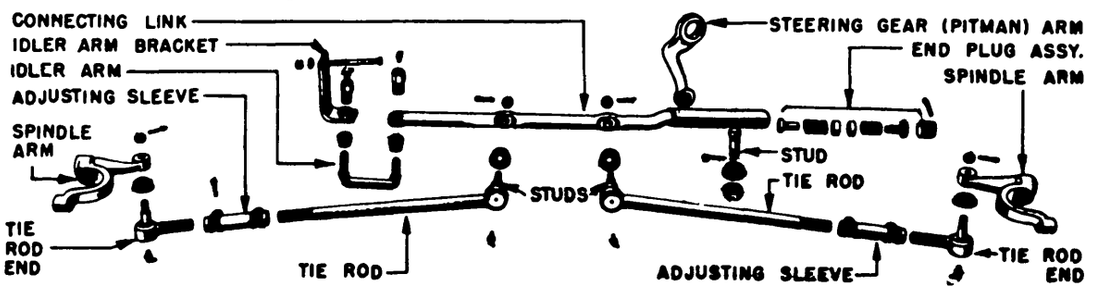
Toe-In Adjustment–(*NOTE*–Steering arm (pitman arm) should be pointing straight-ahead when steering wheel spokes are in horizontal position and steering gear worm is at mid-point of travel). To adjust toe-in, adjust sleeves equally. When tightening clamp bolts, make sure bolts are below top of tie rods.

Idler Arm & Bracket Adjustments–Steering idler designed to operate with 1/8" vertical free play. To reduce, proceed as follows (same procedure used when replacing idler arm or bushings): Remove bracket from frame side rail. Thread bracket and bushing off idler arm, then remove idler arm from steering arm-to-idler arm rod. Remove bushings from idler arm bracket and steering arm-to-idler arm rod, remove

CADILLAC, 1955 CHEVROLET, OLDSMOBILE, PONTIAC STEERING LINKAGE—TYPICAL OF BUICK

lubrication fittings from bushings. Check face of side rail for squareness by placing car on level floor, then measure distance from each side rail to floor. If distances unequal, jack up lower side rail until even with other rail. Place spirit level against inside surface of right hand side rail, adjacent to idler arm position, then establish true perpendicular. Measure distance between edge of level and side rail. Distance represents amount of spacing washers that must be installed between bracket and side rail to correctly position idler arm bracket. Check idler arm bracket for 92° included angle (between inside faces of bracket) and correct if necessary. Replace bushings in bracket and in steering arm-to-idler arm rod. Tighten bushings to 85-100 ft. lbs. torque. Reinstall grease fittings. Place new seals on idler arm. Thread idler arm into idler arm rod bushing until shoulder on arm is 11/16" plus or minus 3/64" from top face of rod when arm is in straight-ahead position. Thread bracket and bushing assembly onto idler arm until shoulder on arm is 19/32" plus or minus 3/64" below bottom side of bracket when bracket is parallel to frame side rail. Mount bracket on frame side rail, installing necessary number of washers between bracket and frame. Tighten attaching bolts to 30-35 ft. lbs. torque.

Ball Socket Adjustment–Whenever steering arm ball stud found to have play in socket, remove cotter pin from end of rod, tighten threaded plug in end of socket until all ball stud end play removed, then back off plug approximately 1 1/2 turns, install new cotter pin. Test adjustment by turning steering arm-to-idler arm rod by hand. Rod must move freely, but there should be no end play at ball stud.



1949-55 FORD TRUCKS

Ford Trucks: Linkage–Consists of a connecting rod between front wheels. Rod has adjustable features at both ends. Spindle arm, attached to connecting rod at its left end, is in turn attached to a one-piece drag link with manual adjustment features at both ends. Rear of drag link is attached to sector shaft arm (pitman arm).

Toe-In Adjustment–Loosen clamp nut at each end of connecting rod, turn connecting rod to lengthen or shorten to obtain desired toe-in.

Drag Link Adjustment–Remove cotter pins from each

CONTINUED ON NEXT PAGE

LINCOLN & MERCURY STEERING LINKAGE—TYPICAL OF FORD

(MANUAL STEERING GEARS)
(C ntinued)

end of drag link. Tighten each drag link plug until drag link ball springs are fully compressed. Back off each plug to first cotter pin hole, then install new cotter pins.

1951-54 HENRY J

H nry J: Linkage—Consists of pitman arm, connected directly to right (long) tie rod. Left (short) tie rod attaches to right tie rod. Tie rods have adjusting links at outside ends for toe-in adjustment.

Toe-In Adjustment—Loosen two clamps on adjusting links at end of each tie rod and turn link to adjust rod length as required.

1948-54 HUDSON (EXC. METROPOLITAN)
1953-54 HUDSON JET

Hudson (Exc. Metropolitan), Jet: Linkage—Consists of center steering arm on frame cross member, linked to each front wheel by adjustable tie rods and to pitman arm by a short drag link.

Toe-In Adjustment—Loosen clamps on end of tie rods. With wheels in straight-ahead position and steering gear on high point, lengthen or shorten tie rods equally until proper toe-in is obtained. Tighten clamps.

Center Steering Arm Adjustments—Using Tool J-2953 adjust arm for centered position as follows: Remove center steering arm nut and front bolt from arm support bracket, install gauge clamp over steering arm, install gauge. Insert bolt at front of gauge in hole in bracket from which bolt removed. Attach screw in center steering arm shaft, adjust gauge rods to contact both sides of front wheel evenly. Repeat procedure for opposite wheel, adjust tie rods equally until reading is same on both sides.

Center Steering Arm Pivot Shaft Replacement Adjustment—Press new shaft in place maintaining the 2.052-2.055" dimension from top of upper spacer and top of lower spacer before drilling and reaming hole for No. 5 taper pin.

1955 HUDSON (EXC. METROPOLITAN)

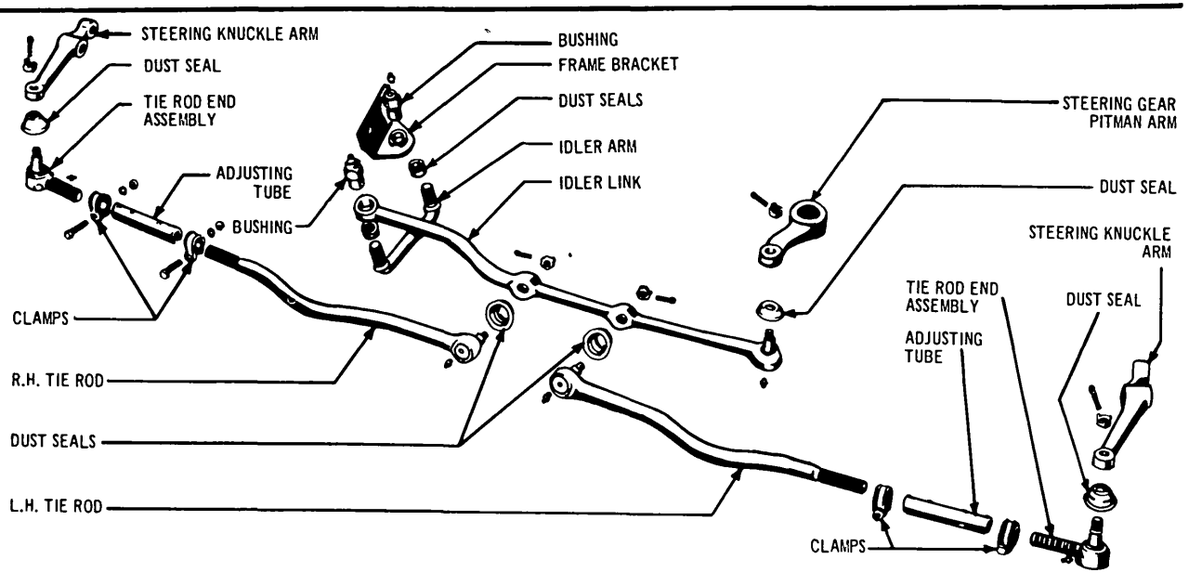
Hudson (Exc. Metropolitan): See Nash below.

1947-55 KAISER
1947-51 FRAZER

Kaiser & Frazer: Linkage - Idler lever is attached to frame crossmember and linked to each front wheel by adjustable tie rods.

Toe-In Adjustment—Loosen clamps on ends of tie rods, lengthen or shorten tie rods equally until desired toe-in is obtained. Check for binding at rod ends caused by cocking of ball seat in relation to stud.

Ball Socket Adjustment (Drag Link)—Remove cotter pin from end of socket and tighten end plug to remove all end play. Back off plug 1/2 turn and install cotter pin. Ball seats must be tight enough to prevent end play and loose enough to permit free movement.



Idler Lever Adjustment—Attach spring scale in hole in idler lever into which drag link connects. Tighten bolt to adjust idler lever bearings until a pull of 8-16 ozs. on spring scale is required to move lever.

1949-55 LINCOLN & MERCURY

Linc ln & M rcury: Linkag —Consists of steering connecting link between steering gear arm (pitman arm) and idler arm, mounted on right frame side rail, and adjustable tie rods between connecting link and each front wheel. Adjustable sleeves provided at outside ends of tie rods for toe-in adjustment.

Toe-In Adjustment—Loosen clamp bolts on adjustable sleeves. Adjust sleeves equally until proper toe-in obtained.

Connecting Link Plug Adjustment—Screw plug in left end of connecting link until it bottoms, back off 2½ turns ± 1/8 turn (1952-53), 1½ turns (1954-55 Mercury), 2-2½ turns ± 1/8 turn (1954-55 Lincoln), align cotter pin holes, install cotter pin.

1955 CHRYSLER, DE SOTO, DODGE V8, PLYMOUTH V8 STEERING LINKAGE

1954-55 METROPOLITAN

Metropolitan, Hudson & Nash Models: Linkage—Consists of adjustable cross tube (for toe-in adjustment). Idler assembly is attached to body sill at right of car and has a double arm, with front arm attached to cross tube and rear arm attached to right tie rod. Steering gear pitman arm is double-levered, with front lever attached to left of cross tube and rear lever attached to left tie rod. Idler assembly is not adjustable.

Toe-In Adjustment—Loosen lock nuts on ends of cross tube, lengthen or shorten cross tube until proper toe-in secured. Tighten lock nuts.

Cross Tube Plug Adjustment—Remove cotter pin, lightly screw plug in as far as it will go, back off to first cotter pin hole in alignment with castellation.

1950-55 NASH (EXC. METROPOLITAN)
1950-55 RAMBLER

Nash (Exc. Metropolitan), Rambler: Consists of steering linkage cross tube between steering gear pitman arm and idler arm, bracketed on right frame side rail. Individual adjustable tie rods are attached to ends of cross tube. Adjusting tubes at outer ends of tie rods provide for toe-in adjustment.

Toe-In Adjustment—Loosen clamps on ends of tubes on tie rods. Turn tubes equally in opposite directions until desired toe-in obtained. Before tightening clamps on adjusting tubes, square ball joints on their studs to prevent excessive steering linkage friction or wear.

1949-55 OLDSMOBILE

Oldsmobile: Linkage—Consists of steering relay rod between pitman arm and idler arm, bracketed to right frame side rail. Individual, adjustable tie rods are attached to center portion of steering relay rod and are provided with adjustable sleeves for toe-in adjustment.

Toe-In Adjustment—Loosen clamp bolts at each end of steering tie rod adjustable sleeves. With steering wheel in straight-ahead position turn tie rod adjusting sleeves to obtain proper toe-in adjustment. Insure that tie rod end ball seats are riding squarely in their seats, then position tie rod to relay rod ball studs to bottom of slot in relay rod. Position clamps on adjusting sleeves so that bolts are below upper surface of adjusting sleeves with edges of clamp **out of slot**, tighten clamp bolts.

Relay Rod Plug Adjustm nt—Draw nut tight, then back off 1/4-3/4 turn, install cotter pin.

Idler Lever & Support Adjustment—Whenever idler arm is disassembled from idler arm support, reassemble so that there is a dimension of 23/32" between upper face of idler arm and shoulder on support.

1946-55 PACKARD

Packard: Linkage—Consists of steering connecting rod between pitman arm and idler lever, bracketed to right frame side member, and individual tie rods (steering cross tubes) between steering connecting rod and each wheel. Adjusting sleeves at outer ends of cross tubes provide means for toe-in adjustment.

CONTINUED ON NEXT PAGE

(MANUAL STEERING GEARS) (C ntinued)

Toe-In Adjustment—Loosen clamps on adjusting sleeves at ends of tie rods. Turn sleeves equally until desired toe-in obtained. Before tightening clamps on sleeves, check each cross tube outer ball socket for being properly centralized.

Conn cting Rod End Plug Adjustment—Draw plugs up tight, then back up 1/4-1/2 turn to align slot with cotter pin hole.

1949-55 PONTIAC

Pontiac: Linkage—Consists of steering connecting rod between pitman arm and idler arm, bracketed on right frame side rail, and individual, adjustable tie rods between steering connecting rod and each front wheel. Tie rods have adjusting sleeves at outer ends for making toe-in adjustment.

Toe-In Adjustm nt—Remove horn button and set gear on high point of worm by turning steering wheel until mark on shaft is exactly at top. Loosen tie rod end clamp bolts and turn tie rod adjusting sleeves equally until desired toe-in is obtained. Turn right tie rod in direction of rotation of wheels to increase toe-in, turn left tie rod in opposite direction to increase toe-in. If front wheels not in straight-ahead position turn both tie rods in same direction (so as not to change toe-in) until error corrected. Tighten clamps on adjusting sleeves with slots in sleeve toward bolts in clamp.

Idl r Lever & Supp rt Adjustment—With lever and support off car, thread idle lever support into bushing until distance between upper face of lever and shoulder on support is approximately 23/32".

St ering Conn cting R d Plug Adjustment—Screw end plugs in until tight, then back off to nearest cotter pin hole alignment and insert new cotter pins (1953-1955), back off 1/4-1/2 turn (1949-52).

1951-55 STUDEBAKER

Studebak r: Linkag—Consists of two adjustable tie rods attached to bell crank mounted at center of frame cross member. Bell crank is attached to steering gear pitman arm by a reach rod (drag link).

T e-In Adjustm nt—If tie rods disassembled, count number of turns when unscrewing tie rod ends from rod to facilitate reassembly. To adjust toe-in, adjust right tie rod (left tie rod on right-hand control cars). When tightened, inner tie rod bolts should be at bottom and horizontal.

Bell Crank Bearing Adjustment—Insert shims between lower thrust washer and shaft until there is no end play. Shaft should, however, turn freely in bearings. Lock nut securely with cotter pin.

1952-55 WILLYS PASS. CARS

Willys Passenger Cars: Linkage—Consists of steering cross tube between pitman arm and idler arm on right frame side rail, and individual, adjustable tie rods between cross tube and each front wheel.

Toe-In Adjustment—Place steering gear pitman arm in straight-ahead position. Since front tread is 58" and rear 57" place straightedge 1/2" out from rear wheels and against front wheels. Adjust tie rods so that both front and rear of front wheels touch straightedge. Correct adjustment will require approximately 1/4 turn of adjusting sleeve of each tie rod.

1946-55 WILLYS UTILITY

Willys Utility: Linkage—Bell crank on frame cross member, linked to each front wheel by adjustable tie rods and to steering gear pitman arm by a steering connecting rod (drag link).

Toe-In Adjustment—Set tie rod end of steering bell crank at right angles to front axle, place straightedge or line against left rear wheel and left front wheel to determine if wheels in straight-ahead position. If front wheel tire does not touch straightedge both at front and rear, adjust left tie rod by loosening clamps on each end and turning tie rod until tire touches straightedge. Check right side in same manner and adjust right tie rod. Adjust toe-in by shortening each tie rod 1/2 turn.

STEERING LINKAGE (POWER STEERING)

Steering linkage on cars equipped with power steering is essentially the same as for manual steering except as noted for "linkage" types below:

BENDIX LINKAGE TYPE

Ford & Mercury (1953-55): One end of power cylinder is bracketed to right frame side rail and the other to steering pitman-to-idler arm rod. Control valve is mounted on right end of steering pitman arm-to-idler arm rod. Rubber bushings are used at each pivot point.

Nash Ambassador 6 (1953-55): Power cylinder replaces cross tube and is bracketed at right body side sill.

Packard (All Models 1953-54; 5560 & 5580 Series 1955): Power cylinder is bracketed at right frame side rail and attached to connecting rod at center between tie rod studs.

MONROE LINKAGE TYPE

Dodge 6 & Plymouth (1954): Power cylinder bracketed to right frame side rail at one end. Cylinder serves as cross tube with steering arm pivoted at left end of power cylinder. Tie rods are pivoted at points near center of power cylinder.

Hudson Wasp & Super Wasp (1954): Power cylinder connects steering gear to center steering arm through medium of a drag link and ball stud in power cylinder unit.

Hudson Wasp & Hornet 6 & 8 (1955), Nash Statesman (1954-55), Nash Ambassador V8 (1955): Power cylinder replaces conventional cross tube and is bracketed to right body side sill.

Kaiser (1953-55): Power cylinder replaces conventional drag link.

Packard 5540 Series (1955): Power cylinder is bracketed at left frame side rail and replaces conventional connecting rod.

Willys Pass. Cars (1954-55): Power cylinder replaces conventional drag link.

ROSS LINKAGE TYPE

Dodge V8 (1954): Power cylinder bracketed to right frame sill and other end attached to steering gear arm. Tie rods are attached to power cylinder near center of cylinder.

SAGINAW LINKAGE TYPE

Hudson Hornet (1954): Power cylinder connects steering gear to center steering arm through medium of a drag link and ball stud in power cylinder unit. Power cylinder is bracketed at right of frame crossmember.

CHEVROLET LINKAGE TYPE

Chevrolet Passenger Cars (1955): Power cylinder is connected to steering relay rod and piston rod is connected to bracket on right frame side rail.

Chevrolet Trucks (1955): Power cylinder is anchored to front axle and piston rod is attached to steering cross rod.

CHEVROLET LINKAGE TYPE

Ch vr l t (1955)

DESCRIPTION: Hydraulic linkage type. Hydraulic power cylinder assembly is mounted on a bracket on the relay rod at one end and to bracket on frame at other end. Hydraulic control valve is attached to left end of steering relay rod and is operated by pitman arm acting on spool valve assembly, through valve shaft. Spool is restricted to a .050" travel to right and left from centered position. Spool valve is normally centered (straight –ahead position) and in this position oil from hydraulic pump flows through center passage of valve body, through annular grooves in spool to annular passages in housing and back to pump. When axial movement of spool occurs with a 3 lb. effort on steering wheel, direct circuit of pump is interrupted by shutting off both direct return passages. Oil is then forced to travel to one end of power cylinder to move cylinder axially on piston shaft. At same time opposite end of power cylinder is open to hydraulic pump return line and permits oil at this end to return through control valve to pump reservoir. Manual steering is possible when hydraulic power not available.

Hydraulic Pump & Reservoir Assembly: Vane type oil pump is mounted on commutator end frame of generator and driven by a splined extension of the special generator armature shaft. Pump contains a combination overload relief valve, which is set to open at 750 psi. at 170°F. and a flow control valve which recirculates oil within pump as required to regulate output volume between 1.1 gallons at idling speed to 1.8 gallons per minute at approximately 3600 RPM. Reservoir encloses pump cover assembly and provides a reserve supply of oil to assure complete filling of hydraulic system. An air chamber in upper part of reservoir and a vented cover attachment provide for the escape of any air that may be introduced into system.

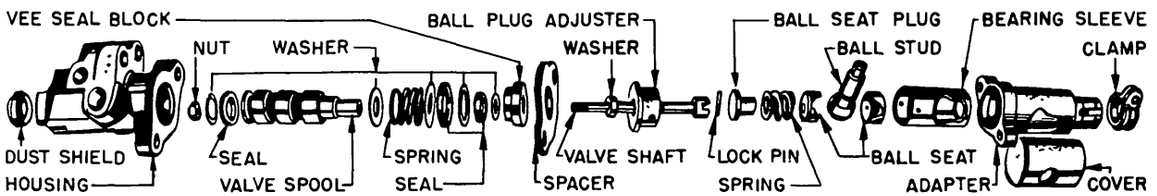
BELT ADJUSTMENT: Loosen outer bracket-to-generator bolt and retaining bolt on generator rear brace. Pull generator out from engine with all slack taken out of belt. Tighten retaining bolts. Push in on belt midway between water pump and generator pulleys with light push. If tension correct there will be 5/16" (6 Cyl.), 13/16" (8 Cyl.), deflection at this point with light push.

LUBRICATION: Checking Fluid Level–Check oil level in reservoir by removing dipstick. Fill to indicated level using Automatic Transmission Fluid "Type A" bearing an "AQ-ATF" number.

Refilling System (After Units Removed or Disconnected): Fill oil reservoir to proper level and let oil remain undisturbed for about two minutes. Raise front end of vehicle so that wheels are off ground. Start engine and run at idle for two minutes. Increase engine speed to approximately 1500 RPM. Turn wheels (off ground) right and left, lightly contacting stops. Lower car and turn wheels right and left on ground. Recheck for leaks. Check oil level and refill as required.

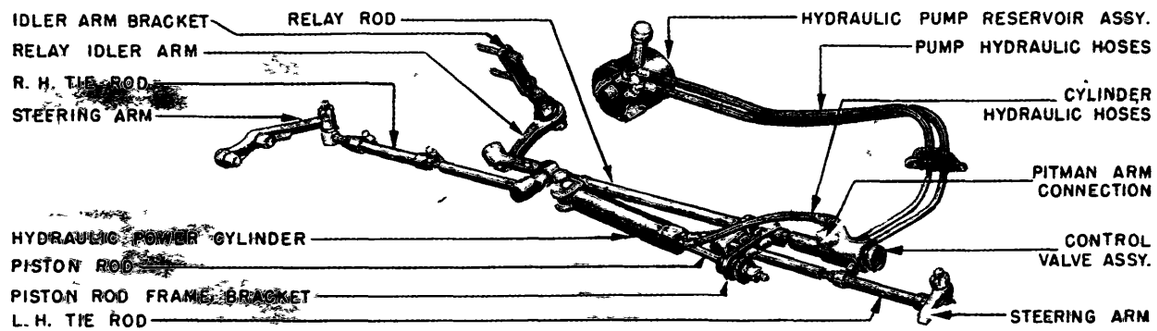
Checking Pump Pressure: Disconnect pressure line at pump connection (smallest, top line). *(CAUTION–* Some fluid will leak out when line is disconnected so provision must be made to collect this drainage). Install checking gauge tool J-5176 (with gauge valve closed) on pump and hose connection *(NOTE–*Adapter Kit J-5900 must be used to adapt pressure gauge to pump). Open gauge valve and run engine at idle. Turn wheels (on ground) against stops. Pressure should not be less than 750 psi. If pressure less than 750 psi., slowly close gauge valve observing gauge for pressure increase. Pressure will increase as valve is closed if pump is good. *(CAUTION–*Do not leave valve closed for more than 15 seconds). If pressure does not increase when valve is closed, difficulty is in pump, which must be removed for service. Shut engine off, remove gauge and valve, reconnect hose to pump if pressure satisfactory. Bleed hydraulic system of air (see above).

HYDRAULIC PUMP: (Removal)–On 6 Cyl. cars, loosen generator-to-bracket retaining bolts and remove fan belt. Pull generator all the way out from engine. On all models, place container under pump and disconnect hydraulic lines from pump allowing oil to drain out of reservoir into container. Remove retaining bolts from pump-to-generator and generator rear brace (V8 models), and remove pump. Complete draining remaining oil from pump reservoir before disassembly.



Disassembly: Remove retaining bolts and sealing washers from pump reservoir-to-pump cover assembly, and remove reservoir. Remove oil filter spring retainer from pump cover assembly. Remove cover plate spring and cover plate and then remove plug and "O" ring, flow spring and pressure relief valve assembly from pump cover assembly. Remove the three retaining bolts from pump cover assembly and remove pump cover from pump body. Remove oil filter and retainer. Remove cam ring, pump rotor and vanes. Remove and discard "O" rings from pump body, cover and cam ring. Remove and discard generator shaft oil seal from pump body.

Inspection: Wash all parts in solvent and dry with a lint free cloth. Check fit of vanes in rotor. Vanes must slide freely, but snugly in slots. Inspect flat face of pressure plate, cam ring, cover, rotor and pump body. If necessary, lap these parts for a good fit. Check surface of pressure relief valve and check fit of valve in pump cover. Correct slight irregularities by polishing.



Reassembly: Coat new "O" rings with Lubriplate and install in pump cover, cam ring and pump body. Install rotor and vanes in pump body with wear pattern or beveled edge of vanes against cam ring inner diameter. Install alignment sleeve in cam ring and install cam ring on pump body *(CAUTION–Wid r edg of cam ring should be installed toward pump body. Be c rtain to align bolt holes in cam ring to body bolt holes. Install rotor with rounded side of splin s toward gen rator end of pump).* Install pressure plate in pump cover and install filter retainer and oil filter. Install cover assembly to pump body, then install plunger and flow spring. Install plug and *"O" ring* assembly, cover plate, and retainer spring. Install filter retainer spring in cover assembly, and install reservoir, retaining bolts and sealing washers.

►*BRASS FITTING SEAT NOTE:* The seats of the brass fittings are the pressed in type and can be replaced in event of a fitting leak by tapping hole in the seat and then pulling the seat by using a bolt threaded into the tapped out seat and a flat washer and nut as an extractor. When installing new seats, align seat in its bore and press it into place by using the correct hose or tube fitting as a pressure tool.

Installati n: Reverse removal procedure.

POWER STEERING CONTROL VALVE ASSEMBLY

CHEVROLET POWER STEERING ASSEMBLY

CONTINUED ON NEXT PAGE

CHEVROLET LINKAGE TYPE

(C ntinu d)

CONTROL VALVE: (R m val)—Raise front of car and place it on stands. Loosen relay rod to control valve clamp and disconnect the two pump to control valve hose connections. Drain fluid into a container and then disconnect the two remaining valve to power cylinder hoses. Remove the retaining nut from the ball stud to pitman arm connection and disconnect control valve from pitman arm. Turn pitman arm to right to clear control valve and unscrew control valve from relay rod. Remove control valve.

Disass mbly: Remove dust shield from control valve housing and remove retaining pin and nut from valve shaft. Remove retaining bolts connecting valve assembly housing to adapter assembly housing and separate the two assemblies. *(NOTE*—Valve spool remains in housing when the two assemblies are separated. The seal at the end of the spool makes it necessary that spool be removed from the end of the housing). Remove spring thrust washer, spring, flat washer, "V" seal assembly, flat washer and spacer from valve shaft. Remove ball stud cover from adapter assembly housing. Push ball stud to the end of the adapter housing and remove lockpin. Remove threaded ball plug adjuster and valve shaft. Remove ball seat plug, spring, ball seats and ball stud. Remove bearing sleeve.

Insp ction: Wash all parts in solvent and dry with a lint free cloth. Inspect all parts for scratches, burrs, distortion, evidence of wear, and replace all parts that are worn or damaged, including mating parts where necessary. Replace all seals, gaskets and covers.

Reassembly: Place ball seat in bearing sleeve and insert sleeve in housing. Insert ball stud in sleeve. Install the remaining ball seat, spring and spring seat in bearing sleeve *(CAUTION—This is the heavier of the two springs used in the control valve).* Install valve shaft in adjuster and screw adjuster into sleeve. Tighten adjuster until it bottoms, and then back if off ¼ turn, plus or minus the amount necessary to install lockpin in nearest hole *(CAUTION*—Be sure ball seats remain in correct position, otherwise there will be insufficient clearance to correctly install retaining pin). Install ball stud cover and install washer and annulus spacer on the valve shaft. Install "V" seal block and ring assembly. Install the annulus washer, spring and spring thrust washer with chamfered side of thrust washer toward spool side. Install spool valve assembly and retaining nut *(CAUTION*—Install spool valve with the "V" seal at the threaded end of valve shaft). Tighten the retaining nut to 25 inch lbs. with a torque wrench and install retaining clip. Make sure that all parts are correctly located before tightening. Insert the assembled valve and adapter assembly into valve housing and install retaining bolts and lockwashers. Fill the end area with GM 4617-M grease and install valve housing dust cover.

Installati n: Install control valve on relay rod so that distance from center of control valve ball stud to center of tie rod end ball stud measures approximately 3 5/8". Tighten control valve clamp *(NOTE*—The clamp securing control valve to relay rod end should be positioned before tightening so that it will not interfere with steering linkage. Reconnect the four hydraulic hoses to control valve and fill system with Automatic Transmission Fluid Type "A".

POWER CYLINDER: (Removal)—Disconnect hydraulic lines connected to cylinder and drain fluid into a container. Remove retaining nut, washer, and rubber grommet from cylinder rod to brace attached to frame. Remove cotter pin, retaining nut, flat washer and bolt from end of power cylinder where it is fastened to relay rod bracket. Remove power cylinder.

Inspection: Inspect seals for leaks around cylinder rod and if leaks are present, replace the seals as follows: Use a hook tool and remove retaining ring. Remove wiper ring, backup washer, backup seal ring and seal *(NOTE*—Piston rod should not be removed unless there are signs of leakage along piston shaft at the shaft seal). Examine brass fitted hose connection seats for cracks or damage and replace if necessary. If other service required on power cylinder, replace the unit.

Installation: Install power cylinder by reversing the reversing the removal procedure. Reconnect the hydraulic lines and fill system with Automatic Transmission Fluid Type "A".

►CHANGES & CORRECTIONS

►*1955 HUDSON WASP & HORNET 6 PUMP PULLEY & BELT PRODUCTION CHANGE (To Increase Pump Spe d):* Effective with Serial No. W-7746 (Wasp), X-7519 (Hornet 6), Power Steering Pump Pulley, Part No. 3145367 (5" diameter), replaces Pulley, Part No. 3143342 (6½" diameter) in order to increase pump speed and oil flow. Belt No. 3145381 (Wasp), No. 3145382 (Hornet 6) must be used with new pulley.

►*1955 HUDSON & NASH V8 PUMP SUPPORT PRODUCTION CHANGE (To Lessen Pump Vibration On Air Conditioned Cars):* Effective Serial No. Y-6374 (Hornet), V-9917, (Ambassador) Power Steering Pump Brace Part No. 3146406, has been incorporated in production to alleviate power steering pump vibration, and is available for use on earlier models. Greater offset end of brace is attached to pump by upper right pump cover cap screw. Pump mounting bracket is also secured at this point. Lockwasher, Part No. GM-114606, must also be used. Discard original pump bracket mounting screw and use Screw, Part No. GM-179841, to secure pump brace to cylinder head. It is necessary to remove power steering pump pulley to remove pump cover cap screw. Prior to loosening pump and compressor drive belt, use belt to hold pulley while loosening screw.

►*1955 HUDSON V8 PUMP RESERVOIR COVER PRODUCTION CHANGE (To Correct Oil Leaks):* Effective Serial Number Y-6448 (Hornet V8) an improved Power Steering Reservoir Cover, Part No. 3119155, became effective in production. New cover incorporates a large inner baffle to correct leaks at cover vent.

DESCRIPTION: Monroe Power Steering is of the "Linkage Type". The power mechanism is built into the steering linkage and is used in conjunction with a standard steering gear. Power steering system consists of the following units:

Hydraulic Pump & Reservoir Assembly: On Dodge and Plymouth, the pump and reservoir assembly is mounted at rear of generator and driven by generator armature shaft. On others, assembly is mounted on engine and is belt-driven by crankshaft. Consists of rotor type pump with built-in relief valve (pre-set to specified limits - See "Testing Hydraulic Oil Pressure" below). A flow control valve limits maximum volume, at high engine speeds, to steering gear requirements.

P w r Link: Serves as drag link in steering linkage. Double-acting piston type. Piston rod is anchored to bracket on right frame side rail, with tie rods connected to ball studs which are firmly attached to the cylinder of the Power Link. The control valve body is an integral part of the Power Link, and moves with the Power Link cylinder. Precision type spool valve is centered in valve body by springs at either end. Stud, attached to pitman arm, extends through valve body, and can be moved in either direction to change position of valve spool thereby actuating Power Link.

►*ADJUSTMENT CAUTION—Whenever hydraulic system disturbed (by disconnecting lines, removal or installation of units, etc.) hydraulic system must be bled to remove air. See Bleeding Hydraulic System below.*

PUMP BELT ADJUSTMENT: (Dodge & Plymouth) Install adjusting tool C-3379 and torque wrench C-3005. Pull torque wrench to 15 ft. lbs. torque and tighten adjusting strap bolt and generator-to-generator bracket bolts. (Hudson 6, Kaiser, Willys) At proper tension, belt should not deflect more than 1/4" when thumb pressure exerted midway between power steering pump and water pump pulleys. (Nash) Tension should be sufficient to prevent belt slippage.

POWER LINK ADJUSTMENT: When it has been determined that valve spool in Power Link is not adjusted properly, adjustment can be made by turning plug in valve end of Power Link in or out, as required, 1/6 turn at a time. In no case should it be necessary to turn it a total of more than 1/2 turn to have a correct adjustment. Road test car and turn plug **IN** if left turn too hard, right turn too easy, poor recovery after

CONTINUED ON NEXT PAGE

MONROE LINKAGE TYPE (Con.inued)

right turns with good recovery after left turns, tendency of vehicle to wander to the right. Turn plug **OUT** if one or more conditions opposite the above exist. Proceed with adjustment of the link valve as follows: Scribe mark on plug in valve end of power link to indicate original position of plug. Remove cotter pin, turn plug in or out 1/6 turn (as determined by symptoms above). If plug held by wire and lead seal, remove seal and after adjustment, replace with cotter pin. Road test vehicle, then if steering action improved but still not correct turn plug an additional 1/6 turn, then road test vehicle again. If necessary, plug can once more be turned an additional 1/6 turn. When steering action is proper, install cotter pin to lock plug in position. If steering action still not correct after plug moved 1/2 of a full turn replace power link.

STEERING GEAR ADJUSTMENTS: Due to reduction of friction and wear, adjustments are made to minimum limits as follows:

Dodge: Remove steering gear chuck from vehicle. Torque required, pulling at 90° to spoke at rim of wheel, should be 1-4 ozs. with no endplay in bearing when roller tooth shaft (steering gear arm) is not assembled in housing. After shaft assembled, pull required to rotate wheel through center position should be 4-8 ozs., with no backlash in the worm and roller shaft at that point.

Hudson, Nash, Plymouth: *See "Gemmer Worm & Roller" in Steering Section.*

Kaiser: The pull at 90° to spoke at rim of wheel should be 1/4 lb. for worm bearing adjustment and 1 lb. pull for worm-to-roller backlash adjustment.

Willys: *See "Ross Cam & Lever" in Steering Section.*

FRONT END ALIGNMENT: All front end adjustments must be set with extreme accuracy due to sensitivity of power steering. Alignments for power steering are:

Hudson Wasp & Hornet (1955): Kingpin Inclination - 3°36'.
Caster - ½° to 1° (1° desired).
Camber - ¼° Neg. to ¼° Pos. (0° desired).
Toe-In - 1/16" to 3/16".

Kaiser: Kingpin Inclination—4-3/4° to 5-1/2°, 5° preferred.
Caster—0° to 1°, 1/2° preferred.
Camber—0° to 3/4°, 1/2° preferred.
Toe-In—1/8" total (1/16" at each wheel).
Toe-Out on Right Turn—Inner wheel 20°, outer 17-1/2°.
Toe-Out on Left Turn—Inner wheel 20°, outer 18-1/2°.

Nash Ambassador V8 & Statesman: Kingpin Inclination-6½°.
Caster—1/2° to 1°, 1° preferred.
Camber—1/4° Neg. to 1/4° Pos., 0° preferred.
Toe-In—1/16" to 3/16".

Willys: Kingpin Inclination - 8¼° crosswise.
Caster - Pos. 1° ± ½°.
Camber - Pos. 1° ± ¼°.
Toe-In - 3/32" to 5/32".

Oth rs: *S e Front Suspension Section on Car Mod l page.*

PITMAN ARM STOP SCREW ADJUSTMENT: Proceed as follows:

Huds n (1954): Turn steering wheel to full right turn and place a 1/16" shim between the stop on the right hand outer steering arm and the stop on the spindle support. With shim in place, adjust the stop screw at pitman arm stop bracket until screw just touches pitman arm, then tighten lock nut securely.

Kaiser: Stops are located on pitman arm and on a bracket on frame side rail. Whenever toe-in adjustment made or any part of steering linkage disturbed pitman arm stops should be adjusted as follows: Loosen lock nuts and turn pitman arm stops in a few turns, turn steering wheel **(without power assistance)** to maximum right turn position until right steering arm touches lower suspension arm outer pivot. Turn adjusting screw in frame bracket out against pitman arm until steering arm is moved approximately 1/8" away from lower suspension arm outer pivot. Tighten lock nut, then repeat this operation for full left turn, adjusting stop screw in pitman arm.

HUDSON (1954) DRAG LINK ADJUSTMENT: Disconnect drag link at stud which extends through valve portion of power cylinder. Set front wheels in straight-ahead position with steering gear on the high point (steering wheel spokes in horizontal position). If drag link will not enter over stud freely, loosen clamp screw and turn drag link arm in or out as required. After adjustment, securely tighten clamp screw and valve stud nut. *NOTE*—If adjusted properly, drag link and stud fit snugly on power cylinder without bind. It is essential that drag link and stud be able to move a few thousandths inch sideways to operate power cylinder. Maintain the 1.990" plus or minus .010" dimension between inner face of thrust washers. If drag link and stud drawn down too tightly on power link, steering effort will increase and wheels will not return properly after a turn. It may be necessary to disengage drag link from stud and remove one of two metal washers on stud and rubber cushion and the drag link. If this does not correct condition, it may be necessary to replace stud or drag link.

LUBRICATION: *CAUTION—Power Steering Unit and Steering Gear are lubricated separately with DIFFERENT lubricants:*

Power Steering System: Check fluid level every 2,000 miles (Dodge & Plymouth 1000 miles), maintain at indicated level near top of reservoir (Dodge & Plymouth 1/2" above highest point of filter element). Check for leaks before adding fluid to system. Capacity of system is 3 pints.

Recommended Fluid—(Dodge & Plymouth) SAE 10-W Engine Oil when temperatures consistently above 10° F. above zero, and SAE 5-W when temperatures reach 10° F. below zero and remain consistently below 10° F. above zero. At extreme high temperatures use SAE 30 Engine Oil. (Others) Automatic Transmission Fluid (Type A—AQ-ATF).

Draining System (Dodge & Plymouth): *(NOTE—Extreme care should be exercised to prevent dirt from nt ring res rvoir while cover is removed. To prevent damage to filter element, do not insert sharp objects into reservoir. Do n t disturb filter lem nt as periodic changes of this unit are not required.)* Disconnect high pressure (small) hose at power steering unit, place end of hose in suitable container. While holding hose in container start engine and allow to idle until all fluid is forced from unit (CAUTION—Do not run engine above idle speed). As soon as fluid starts to show great quantities of air bubbles, stop engine. Reconnect high pressure hose, refill.

BLEEDING (REFILLING) HYDRAULIC SYSTEM (HUDSON): *Loosen hose connections at booster cylinder* valve; with hoses disconnected at pump, fill hoses with fluid (Type A—AQ-ATF) until fluid runs out at the hose connections at booster cylinder free of air bubbles; then tighten connections at booster cylinder, while keeping hoses full of liquid. Install hose connections at oil pump and tighten securely. Fill oil pump reservoir to mark with recommended fluid. Fill cooling system. Start engine and run at idle speed for approximately 10 minutes to allow hydraulic system to clear itself of air that may be trapped in the system. *(CAUTION—Do not turn th steering wheel during this 10 minute p riod).* Recheck oil level. Install reservoir gasket, cover, cover attaching screw, flat washer and lock washer (use new gasket). Check all hose connections for leaks. *NOTE*—If oil pump is noisy and fluid level is up to mark in reservoir and all connections are tight, place car in service. Noise will disappear after three or four days usage. Pump noise is caused by air forced into the oil. The air will be gradually dissipated during usage. If care is taken during filling and while connecting hoses, condition should not occur.

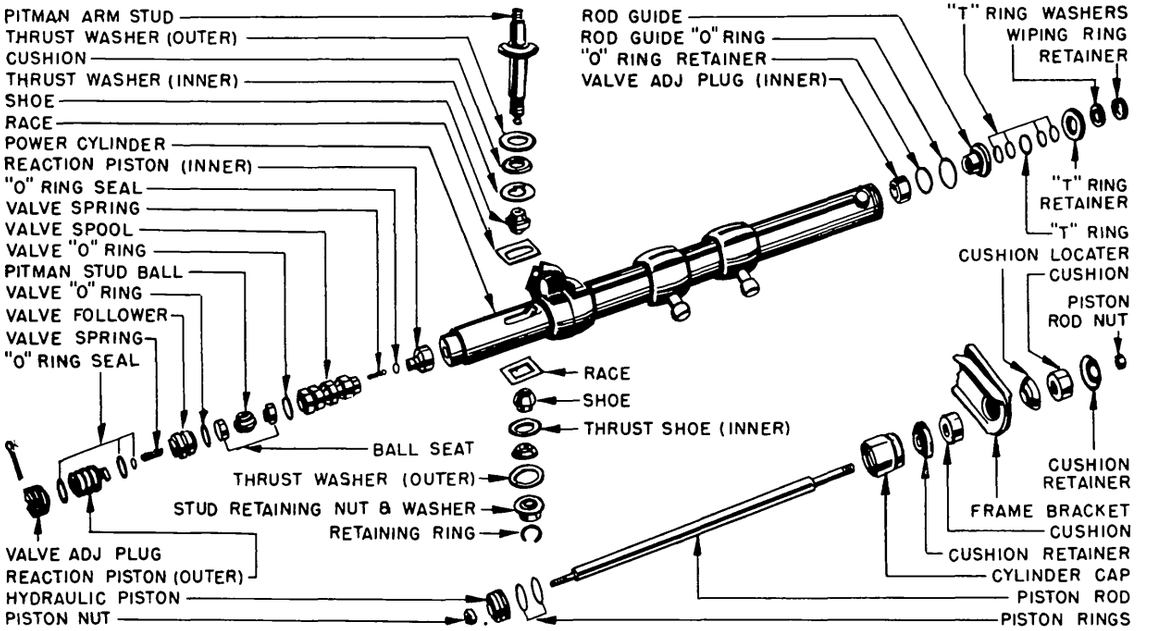
BLEEDING (REFILLING) HYDRAULIC SYSTEM (OTHERS): Fill reservoir to within one inch of top (Dodge & Plymouth slightly above normal). Start engine and allow to run for a short time to circulate oil through hoses. With engine running at idle speed, turn steering wheel back and forth several times from extreme positions to bleed any remaining air out of system. Check oil level in reservoir, refill to proper level.

TESTING: If Power Steering operation is unsatisfactory and before making any tests be sure pump belt tension is correct, fluid level proper, leaks eliminated; that wheel alignment, pressure and condition of tires and shock absorbers are satisfactory. Then make tests as follows:

Steering Effort: Start engine. With engine running at idle speed (Automatic Transmission in neutral), front wheels on dry, smooth concrete (or smooth steel plates), a 3-10 lb. pull should be sufficient to turn steering wheel one full turn in either direction from center. If otherwise see "Trouble Shooting" below.

Hydraulic Pressure (Dodg & Plym uth): With engine turned off, connect pressure gauge in pressure line between pump and hose with shut-off valve open. Start engine. If, when turning steering wheel to either extreme position, the gauge does not show 500 lbs. per square inch, slowly close valve. If pressure does not gradually increase as the valve is closed, flow control valve may be stuck in open position or drive coupling may be broken. *(NOTE*—If gauge not available, a fairly accurate way of making test is as follows: Start engine and turn wheel to both extreme

CONTINUED ON NEXT PAGE



MONROE LINKAGE TYPE
(C ntinu d)

positions. If high pressure hose flexes, pump is in good condition. If high pressure hose does not flex, lack of pressure from pump is indicated.) Turn engine off, and remove reservoir cover. Restart engine and turn steering wheel. If oil flows through filter, flow control valve plunger is stuck. Turn engine off and remove gauge. Insert a 1/4" blunt probe against valve plunger. If valve moves inward, it was stuck. Recheck pressure and if gauge registers less than 500 lbs. per square inch, a broken coupling is indicated and must be replaced. Remove pump from generator. If either coupling is broken, turn pump shaft by hand at least ten revolutions. If shaft turns freely, install a new coupling on both the pump and generator shafts. If pump shaft binds when turned by hand, replace both pump and couplings. If generator armature shaft is damaged, replace necessary parts.

Hydraulic Pressur (Oth rs): With engine turned off, connect pressure gauge in pressure line at pump, turn gauge to open position. Start engine and idle for approximately two minutes for fluid to reach operating temperature. With gauge valve open, turn wheels against a curb or other suitable object, maintain sufficient force on steering wheel to keep hydraulic power applied to steering linkage and front wheels. Note pressure on gauge, then release steering wheel. *CAUTION–Do not maintain force on steering wheel for any xt nded p riod of time to avoid undue wear in hydraulic system.* If pressure noted was 500-800 psi., power link and pump are operating properly and it is unnecessary to continue further. If less than 500 psi. close gauge valve and note pressure developed by pump, then open gauge valve. *CAUTION–Do not leave gauge valve closed for more than 3 or 4 seconds.* If pressure developed by pump increases to 500-800 psi. (650-900 psi. on Ambassador V8 & Hornet V8) fault is in Power Link. Check the pitman arm for binding on valve body. If pitman arm not binding, remove Power Link piston and rod assembly. Check piston and rings, replace if necessary. Make another pressure check and if pressure still low, replace Power Link. If pressure does not increase to 500-800 psi. (650-900 psi. on Ambassador V8 & Hornet V8) replace relief valve spring and flow control valve spring. If pressure still low, pump must be removed and overhauled. If pressure ever exceeds 800 psi. (900 psi. on Ambassador V8 and Hornet V8), replace relief and flow control valve unit.

TROUBLE SHOOTING: *Diagnose trouble as follows:*

Hard Ste ring in B th Directions: **1)** Leak in system, fluid level low, insufficient fluid flow in system due to plugged flow restrictor or hoses.
2) Steering gear and linkage not lubricated, pitman arm and stud binding on power link, bend in power link piston rod, bind in steering column or gear.
3) Low pump pressure caused by stuck relief and flow control valve, weak or broken flow control valve spring, weak or broken relief valve spring, rotors not turning, rotors worn, pump body or cover worn.
4) Loss of pressure in power link caused by internal fluid leak past piston or valve.

MONROE LINKAGE TYPE POWER STEERING UNIT

5) Valve in power link misaligned or sticking.
6) Tire pressure too low, improper front end alignment.
7) Pump belt slipping or broken.

Hard Steering in one Direction Only: **1)** Valve in power link misaligned or sticking.
2) Tire pressure too low, improper front end alignment.
3) Bend in power link piston rod, bind in steering column or gear.

Poor Recovery on Turns: **1)** Tire pressure too low, improper front end alignment.
2) Pitman arm and stud binding on power link, bind in steering column or gear, bind in steering knuckles.
3) Bend in power link piston rod, or valve in power link misaligned or sticking.

Vehicle Attempts to Turn unless Force Applied to hold Steering Wheel: **1)** Tire pressure uneven.
2) Pitman arm and stud binding on power link.
3) Valve in power link misaligned or sticking.

Noise: **1)** Pump belt tension is incorrect, pump drive pulley retaining bolt loose, pump drive pulley key does not fit, pump shaft bearing worn, worn bushings in pump body or cover.
2) Low fluid level, dirt and sludge in pump.
3) Pitman arm stud loose, tie rod clamps tightened in wrong position, power link bracket on frame hitting lower suspension arm.
4) Restricted air vent in reservoir cover.
5) Noise in power link valve.

REMOVAL & INSTALLATION OF VALVE & POWER CYLINDER (POWER LINK): Proceed as follows:

D dg & Plym uth: Raise vehicle (preferably with hoist). Remove right and left tie rod ends at steering knuckle arms. Place drain pan beneath power unit at hose fittings. Disconnect hoses, plug hose fittings and cap fittings on unit. *(CAUTION–After fittings on unit have been capped, care should be exercised to prevent movement of the unit on piston rod. If steering wheel is turned or if other force is put on unit, seals can be blown. Do not start engine after removing hoses and putting plugs in lines.)* Disconnect power unit from steering arm at steering arm attaching stud. *(CAUTION–Power steering unit should be prevented from dropping by either holding or tying in place. Tap on steering arm, not on attaching stud and do not pry between valve and steering gear arm).* Holding piston rod at flat section with 9/16" open end wrench, remove piston rod attaching nut. Remove outer linkage bracket cushion retainer and cushion. Disconnect piston rod from frame bracket. Remove tie rods from power unit if necessary and replace before installing in vehicle. To install, reverse removal procedure. Tighten nuts to 45-75 ft. lbs. torque. Check oil level in reservoir and refill (see Lubrication above) as necessary.

Hudson (1954): Turn front wheels full left. Remove cotter pin from drag link ball stud at valve shaft and remove castle nut (7/8" wrench). Remove drag link ball stud from valve stud, using Tool J-2781. Remove cotter pin, end plug, safety plug, spring and ball seat, then disconnect valve and cylinder from center steering arm. Raise car and place on stand jacks. Disconnect piston rod at support bracket at No. 3 crossmember by removing cotter pin and lock nut (3/4" wrench) and push the piston rod through bracket and remove piston shaft washers, rubber bushings

CONTINUED ON NEXT PAGE

MONROE LINKAGE TYPE (Continu d)

and retaining washers. Disconnect hoses at oil pump and lift valve and power cylinder up through engine compartment. To install, connect piston to frame bracket and tighten castellated nut until **two full threads** of piston rod extend beyond top of nut. (DO NOT exceed this limit). Assemble drag link onto valve stud and install nut and cotter pin. Tighten drag link arm-to-valve stud nut to 50-60 ft. lbs. torque, then tighten other valve stud nut to give equal compression of rubber cushion against power cylinder. It is essential that valve and drag link are able to move a few thousandths of an inch sideways to operate power cylinder spool valve. (CAUTION—Maintain the 1.990" plus or minus .010" dimension between inner face of thrust washers. If this dimension not held, drag link and stud may be drawn down too tightly on power cylinder, increasing steering effort so that wheels will not return properly after making a turn. Install washers in sequence (reverse to that in which removed). It may be necessary to remove one of metal thrust washers to correct an overtight condition). Assemble steering arm ball (center) into slot in unit and install ball seat, spring and spring seat plug. Install hoses, but do not tighten. Fill hoses with fluid until fluid runs out at hose connections at booster cylinder free of air bubbles, then tighten connections at booster cylinder, while keeping hoses full of fluid. Install hose connections and tighten securely. Refill system (See Bleeding (Refilling) Hydraulic System (Hudson) above).

Hudson (1955), Nash: Disconnect oil hoses from the unit, and disconnect rod from side sill bracket. Disconnect tie rods from cylinder and valve assembly. Remove pitman arm stud adjusting nuts, washers, cushions and spacers and remove cylinder and valve assembly from pitman arm. To install, reverse the removal procedure. Tighten inner nut on pitman arm stud until there is sufficient tension on rubber cushions to prevent rattles and grease leakage and still permit free movement of the stud.

Kaiser & Willys: Raise the vehicle on hoist, remove cotter pins, then back out plugs in ends of tie rods to disconnect tie rods from ball studs of power link. Disconnect hoses at power link, after noting position of hose connectors so they can be replaced in same position. Cap hose ends and install plugs in power link. Remove cotter pin and nut attaching pitman arm to stud in power link. Tap on side of pitman arm with hammer to loosen stud. Do not pry between pitman arm and valve as this may damage washers on stud. Remove cotter pin, nut, retainers, and insulator from end of piston rod to disconnect piston rod from frame bracket, remove power link. To install, reverse removal procedures. Make certain dirt does not enter fluid lines when installing unit. Use torque wrench to tighten pitman arm stud nut to 55-65 ft. lbs. torque. Pitman arm and stud should fit snugly on power link but not bind. It is essential that pitman arm and stud are able to move a few thousandths inch sideways to operate power link valve. Lubricate stud. Install tie rods to power link, turn plugs in tight, then back out 1/4 to 1/2 turn. Check and adjust toe-in and steering wheel alignment if tie rod length was disturbed. Bleed system, check for leaks, then check operation.

VALVE & POWER CYLINDER (POWER LINK) OVERHAUL: Valve Disassembly: Remove valve and power cylinder assembly from vehicle (See Removal & Installation above), then proceed as follows:

Dodge & Plymouth - Clean outside of the valve and cylinder assembly in suitable solvent. Remove cotter pin from outer adjusting plug. Using a scribe, mark the location of the adjusting plug (to assist in making final adjustment *(CAUTION—Do not use center punch for marking).* Count number of turns, turning adjusting plug in until it bottoms, and record. *(CAUTION—Do not bottom adjusting plug unless attaching stud has been left assembled through ball, otherwise damage to ball may result from crushing.)* Remove outer adjusting plug. Note air vent in plug to see that it is open. Disassemble and remove steering arm stud. Using attaching stud, or brass rod, inserted through steering arm ball pull the right turn (outer) reaction piston, spring, follower and ball seat toward outer end of valve bore as far as possible. Remove attaching stud and ball. Insert finger in valve bore and push out assembly. Remove valve spool by tapping valve end on wooden bench or block of wood. Remove spring and left turn (inner) reaction piston.

Hudson, Kaiser, Nash, Willys - *(NOTE* - Kaiser recommends that spool valve springs and parts inside valve body **not** be removed or replaced. These parts are selectively fit at time of manufacture). On Hudson, disconnect hoses from power cylinder and valve. Remove cotter pin and outside spring seat plug to disconnect unit from center steering arm. All cars, clean outside of valve and cylinder assembly thoroughly. Punch mark adjusting plug to insure accurate reassembly, remove plug, then remove the valve spring, follower (or retainer), ball and ball seat. Hold unit in vertical position and tap valve end lightly on wooden bench or block to allow valve spool to slide out of valve body. Remove inside valve spring. *NOTE*—Inner adjusting plug is staked in position and cannot be removed. On Hornet and Ambassador V8, valve spool inner components may be replaced as well as "O" rings. Valve spool is not supplied for service due to possibility of improper spool to port alignment of replacement part. On Statesman, valve parts are supplied only with cylinder and valve assembly as total length of components must be held to close tolerances to maintain correct valve spool port alignment.

Cylinder Disassembly: Remove cylinder cap (or unscrew cylinder plug) from cylinder. Pull out on piston rod to remove piston and guide assembly. *(CAUTION—Except on Kaiser and Willys, rod guide should not be disassembled unless unit has been leaking at that point).* To disassemble rod guide (except Kaiser and Willys), use screwdriver to separate "T" ring retainer from rod guide. Remove two outer phenolic rings, "T" ring and two inner phenolic rings. Remove large "O" ring from piston rod guide and discard. Disassemble "T" ring retainer only when wiper needs replacement. Using screwdriver, remove wiping ring from "T" ring retainer. To reassemble rod guide, reverse removal procedure (Lubricate rings with Lubriplate or equivalent).

Inspection: Thoroughly clean all parts in suitable solvent. Remove "O" rings and discard. Inspect all parts for nicks, scores, and burrs. (NOTE—Valve spool not replaceable as separate item, due to close fits). Small scores and burrs can be removed with crocus cloth, if used carefully. Make sure rings rotate freely in piston ring grooves. (NOTE—Piston and rod replaceable as an assembly).

Valve Reassembly (Dodge & Plymouth): Reverse the removal procedures. Lubricate new "O" rings with Lubriplate or equivalent. To facilitate assembly, place inner reaction piston spring in recess in spool and hold with Lubriplate or equivalent. Back off adjusting plug same number of turns as recorded when valve disassembled. Check valve assembly operation by placing a long pin through ball, you should be able to slightly move valve assembly back and forth in bore. Do not install cotter pin until unit has been installed in vehicle and power link adjustment checked. NOTE—Overtightening of steering arm stud will create an increase in steering effort and cause poor recovery from turns.

Valve Reassembly (Hudson, Kaiser, Nash, Willys): Reverse removal procedures. Line up adjusting plug punch mark made at disassembly.

Cylinder Reassembly: Reverse removal procedures. Lubricate rings with Lubriplate or equivalent. Be sure rings locked in position and staggered. Wet "T" ring seals (where applicable) with power steering fluid.

PUMP OVERHAUL: References are as follows:

Dodge & Plymouth: *See "Gemmer Hydraguid".*

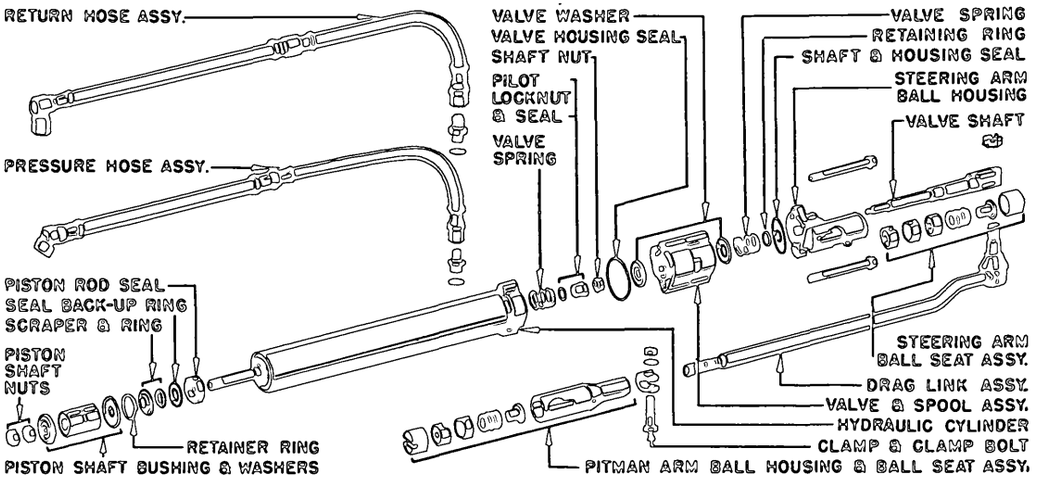
Hudson Wasp & Hornet 6: *See Vickers Pump data under "Eaton & Vickers Hydraulic Power Pumps".*

Hudson Hornet 8, Nash, Kaiser, Willys: *See Eaton Pump data under "Eaton & Vickers Hydraulic Power Pumps".*

STEERING LINKAGE : *See "Steering Linkage".*

SAGINAW LINKAGE TYPE

Hudson Hornet, Model 7D (1954)



DESCRIPTION: Hydraulic linkage type. Power unit is a complete assembly with control valve built-in the end of the hydraulic power cylinder. The unit is connected in the steering linkage between the drag link and the center steering arm on the frame front cross-member (drag link connected to spool valve stem, center steering arm connected directly to same end of power cylinder) so that steering wheel motion is transmitted to the wheels mechanically to permit manual steering when hydraulic power is not available. Power unit piston rod is attached to a bracket on the frame so that hydraulic pressure tends to move the hydraulic cylinder on the stationary piston. Hydraulic application is controlled by the spool valve which is connected directly to the drag link.

Hydraulic Pump & Reservoir Assembly: Vickers vane type hydraulic pump. *See "Vickers & Eaton Hydraulic Power Pumps" in Power Steering Section*

BELT ADJUSTMENT: Loosen two bolts attaching pump to mounting bracket, move pump upward until belt deflection midway between fan and pump pulleys is ¼" with thumb pressure, tighten attaching bolts to 25-30 ft. lbs.

POWER CYLINDER ADJUSTMENT: Remove Power Cylinder Assembly (See Removal & Installation below). Clamp head of valve shaft in vise so that shaft is in a vertical position. While holding spool shaft nut, remove pilot lock nut and loosen shaft nut. Tighten shaft nut until a definite resistance is met, then back off nut ½ turn. A minimum of 5/16" thread should be showing beyond nut. (*NOTE*—If there is less than 5/16" thread, the inner valve washer has caught on the spool shoulder and is not centralized on valve shaft). After determining that 5/16" dimension is correct, screw on pilot lock nut by hand. Using the two valve body-to-cylinder attaching screws and two 3/8"-16 nuts, assemble the valve body and shaft assembly together (tighten to 12-15 ft. lbs. torque). Tighten valve shaft nut to 9-11 ft. lbs. torque. Release tension and tighten to 3-5 ft. lbs. torque. While holding valve shaft nut against turning, tighten pilot lock nut to 5-10 ft. lbs. After final tightening, use a fine punch and working through one of the small holes in the pilot lock nut, make a punch mark to stake lock nut to valve shaft. Place power cylinder on valve assembly and install attaching screws (dip threads in sealer). (CAUTION—Do not gouge or slice pilot lock nut seal when assembling cylinder to valve assembly). Tighten valve housing attaching screws to 12-15 ft. lbs. torque. Install valve fittings and seals in their proper places. Assemble pressure and return hoses to their proper fittings on valve body assembly. Install assembly on car (See Removal & Installation below).

STEERING LINKAGE ADJUSTMENTS: Pitman Arm & Stop Screw—Turn steering wheel to full right hand turn, place a 1/16" shim between stop on right hand outer steering arm and stop on spindle support. With shim in place, adjust stop screw at pitman arm stop bracket until screw just touches pitman arm, then tighten lock nut securely.

SAGINAW LINKAGE TYPE POWER STEERING UNIT

Drag Link—Set front wheel in straight-ahead position with steering gear on high point (steering wheel spokes in horizontal position). Drag link stud should hole in valve shaft freely. If not, disconnect drag link at pitman arm, loosen clamp at junction of male and female connection of drag link and turn drag link in or out as required. After adjustment, tighten clamp screw securely. Adjust drag link end plug by tightening plug to end of travel and back off to nearest cotter pin hole. Install and secure cotter pin. Install drag link, nut and cotter pin to valve shaft.

LUBRICATION: *CAUTION—Power Steering System and Steering Gear are lubricated separately and with different lubricants:*

Power Steering System: Check fluid level in reservoir every 2000 miles, add fluid to maintain level.

Checking Fluid Level—Thoroughly clean top of reservoir, remove cover, maintain fluid level even with mark near top of reservoir. Use Automatic Transmission Fluid Type A.

Refilling System (After units removed or disconnected)—*CAUTION—Fill exactly as follows to prevent air entering the system which will cause pump to be noisy:*

1) With both hydraulic hoses disconnected from the pump, loosen hose connection at the power unit, fill the hoses with fluid and allow it to run out at the power cylinder end until it is free of air bubbles, tighten connections at power cylinder end, connect hoses to pump. *CAUTION*—keep hoses filled with fluid while making the connections.

2) Fill oil pump reservoir to the full mark. Start the engine and run it at idle speed for approximately 10 minutes to remove air which may be trapped in system. *CAUTION—DO NOT TURN STEERING WHEEL DURING THIS PERIOD.*

3) Recheck fluid level, add fluid as required. Install reservoir cover. Check all connections for leaks.

NOTE—If pump is noisy after system has been refilled exactly as noted above, this noise should disappear after several days useage when air in fluid should be dissipated.

BLEEDING HYDRAULIC SYSTEM: Follow steps 2) and 3) of "Refilling System" under LUBRICATION above.

TESTING: If power steering operation is unsatisfactory and cause unknown, refer to "Trouble Shooting" below, and starting with easiest operations first continue to check until trouble found.

Steering Effort: Attach spring scale to spoke near rim of steering wheel. With engine running at idle speed and transmission in neutral, and with front wheels on dry, smooth concrete floor or smooth steel plates, a 3-8 lb. pull should be sufficient to turn wheel one full turn in either direction from center. If steering effort in both directions greater than 8 lbs. at rim of steering wheel, it indicates hard steering. (See "Hard Steering in Both Directions" in Trouble Shooting). If steering effort is more than 8 lbs. in one direction only and very low in other direction refer to "Hard Steering in One Direction Only" in Trouble Shooting for possible causes.

Hydraulic Pressure: If "Trouble Shooting" of items in system other than pump does not disclose trouble, difficulty may lie in pump. To check pump proceed as follows: With engine off, install pressure gauge in pressure line. Turn gauge valve to open position. Start engine and let it idle for approximately two minutes to permit fluid to reach operating temperature. With gauge valve open, turn wheels against a curb or other suitable object and maintain sufficient force on steering wheel to keep hydraulic pressure applied to steering linkage and front wheels. Note pressure shown on gauge, then release steering wheel. (*CAUTION—Do not maintain force on steering wheel for any extended period of time, as this may cause undue wear in hydraulic system).* If pressure reading above is 500-800 psi., the power cylinder and pump are operating properly and it is unnecessary to continue further. If reading less than 500 psi., close gauge valve and note pressure developed by pump, then open gauge valve (*CAUTION—Do not leave gauge valve closed for more than 3 or 4 seconds).* If pressure reading increases to 500-800 psi., pump is delivering sufficient pressure and

CONTINUED ON NEXT PAGE

SAGINAW LINKAGE TYPE (Continued)

fault is in power cylinder (See Power Cylinder Check below). If pressure did not increase to 500-800 psi., replace relief and flow control valve unit and flow control spring. If pressure still low, pump must be removed and overhauled. If pressure ever exceeds 800 psi., replace relief and flow control valve unit.

POWER CYLINDER CHECK: Check drag link and stud to make sure it does not bind on valve body. Correct if necessary (See Steering Linkage Adjustment above). If drag link is not binding, remove power cylinder piston and rod assembly. Check piston and rings and replace if necessary. Make another pressure test and, if pressure still low, replace power cylinder.

TROUBLE SHOOTING: *Diagnose trouble as follows:*

Hard Steering in Both Directions—Leak in steering system, pump belt slipping or broken, fluid level low, steering gear and linkage not lubricated, tire pressure low, drag link and stud binding on power cylinder, power cylinder piston rod bent, low pump pressure, loss of pressure in power cylinder, insufficient fluid in system, bind in steering column or gear, improper front end alignment, valve in power cylinder misaligned or sticking.

Leaks: At hose fittings, pump body, valve end; around piston rod on power cylinder.

Hard Steering in One Direction Only: Tire pressure too low, power cylinder piston rod bent, bind in steering column or gear, improper front end alignment, valve in power cylinder misaligned or sticking.

Car Attempts to Turn Unless Force Applied to Hold Steering Wheel: Tire pressure uneven, drag link and stud binding on power cylinder, valve in power cylinder misaligned or sticking.

Poor Recovery on Turns: Tire pressure too low, drag link and stud binding on power cylinder, bind in steering column or gear, bind in power cylinder piston rod, improper front end alignment, valve in power cylinder misaligned or sticking.

Noise—Pump belt tension incorrect, fluid level low, pump drive pulley retaining bolt loose, pump drive pulley key does not fit properly, pump shaft bearing worn, bushings worn in pump body or cover, dirt and sludge in pump, drag link stud loose.

REMOVAL & INSTALLATION: Proceed as follows:

Reservoir & Pump Assembly: Removal—Raise hood and drain radiator by opening cock at lower right side of radiator. Remove upper radiator hose. Disconnect hydraulic hoses at unions on pump (*NOTE*—Secure ends of hoses in raised position at pump unions to prevent oil drainage). Remove drive pulley attaching nut, lockwasher and flat washer (¾" wrench). Loosen two pump-to-bracket screws (9/16" wrench). Slide pump toward engine and remove pulley belt. Remove pump pulley by tapping lightly on back face with a soft hammer. Remove two screws attaching pump to bracket (9/16" wrench). Remove reservoir and pump assembly to bench for draining and repair.

Installation—Reverse removal procedure. Adjust belt tension, then follow procedure outlined for "Refilling System" under LUBRICATION.

Valve & Power Cylinder: Removal—Turn front wheels fully to left. Remove cotter pin from drag link ball stud at valve shaft and remove castle nut (7/8" wrench). Remove drag link ball stud from valve shaft with Tool J-2781. Remove cotter pin, end plug, safety plug, spring and ball seat and disconnect valve and cylinder assembly from center steering arm. Raise car and place on stand jacks. Disconnect piston rod at support bracket at No. 3 crossmember by removing lock nut and retaining nut (¾" wrench) and push the piston rod through bracket. Remove piston shaft washers, rubber bushings and retaining washers. Disconnect hoses at oil pump and lift valve and power cylinder up through engine compartment (*NOTE*—Use screw caps to plug both hoses and both pump fittings to keep oil from draining out).

Installation—Enter complete assembly through hood opening. Attach piston rod to bracket at No. 3 crossmember; assemble one piston shaft washer, one rubber bushing and one rubber bushing retainer on each side of bracket. Cupped portions of washers should be toward rubber bushings. Install one attaching nut and compress rubber bushing to 1 11/16-1 3/4". Tighten securely. Install second nut and tighten securely. Second nut must be flush with end of shaft. Attach steering arm ball stud housing to center steering arm. Install ball seat on side of center steering arm. Enter steering arm ball, ball seat, dust seal, spring, safety plug and end plug. Adjust end plug by tightening plug to end of travel and backing off to nearest cotter pin hole. Install and secure cotter pin. Install drag link, nut and cotter pin to valve shaft. Refill system following procedure outlined for "Refilling System" under LUBRICATION.

VALVE & POWER CYLINDER OVERHAUL: Disassembly—Clean outside of valve and cylinder assembly thoroughly. Remove both hoses from valve body and inspect hoses for wear or cracks. Replace if necessary (13/16" and 7/8" fittings). Remove two screws attaching steering arm ball housing and the valve and spool assembly to hydraulic cylinder assembly (*CAUTION—This is a spring loaded assembly and screws should be loosened equally until spring is relieved).* Overhaul components as follows:

Hydraulic Cylinder: Hydraulic cylinder serviced only as an assembly. Following parts **only** are furnished separately: Retaining lock ring, scraper back-up ring scraper, seal back-up ring, piston rod seal.

Piston Rod Seal—(*NOTE—Piston seal should not be removed unless there are signs of leakage around the piston shaft seal).* To replace seal, proceed as follows: Use a hook tool or screwdriver and remove retaining lock ring. Remove scraper back-up ring, scraper, seal back-up ring and piston rod seal (*CAUTION—When removing seal do not damage piston rod).* Install NEW oil seal, reversing removal procedure.

Valve: Remove valve centering spring. Remove "O" ring from pilot lock nut. While holding spool shaft nut, remove pilot lock nut (11/16" wrench). Remove control valve assembly with spools from valve shaft. Remove valve washer from valve shaft. Remove "O" ring seals from each end of valve body. Remove spools from valve housing, being careful not to damage or drop either the spools or housing (*NOTE*—Check spools and housing bore for excessive wear). Remove pressure and return fittings and seals from valve housing. DO NOT place housing in vise. Remove valve washer and valve return spring. Push valve shaft through steering arm ball housing so that valve shaft "O" ring seal may be accessible. Remove shaft retaining ring and seal. Remove valve shaft from steering arm ball stud housing. Clean all parts in a clean solvent and blow dry with compressed air.

Reassembly: Valve & Power Cylinder—Clamp head of valve shaft in a vise so that shaft is in a vertical position, install steering arm ball housing over valve shaft. Install new valve shaft "O" ring and spiral retaining ring. Place valve return spring and valve washer over valve shaft and into steering arm ball housing (*NOTE*—Install valve washers with machined surfaces toward valve spools). Assemble valve spools into valve housing. Insert largest diameter spool in end of housing having three small holes (*CAUTION*—Use care to prevent scratching or nicking spools or bore in housing). Install "O" ring seal in circular housing groove. Slide valve housing and spool assembly carefully over valve shaft. The three holes in the valve housing should point up toward threaded end of valve shaft. Install valve washer over valve shaft. Apply Lubriplate to valve shaft threads. Install shaft nut until a definite resistance is felt. Back off ½ turn. A minimum of 5/16" thread should be showing beyond nut. (*NOTE*—If there is less than 5/16" thread, the inner valve washer has caught on spool shoulder and is not centralized on valve shaft). After determining that 5/16" dimension is correct, screw on pilot lock nut **by hand.** Using the two valve body-to-cylinder attaching screws and two 3/8"-16 nuts, assemble valve body and shaft together (tighten to 12-15 ft. lbs. torque). Tighten valve shaft nut to 9-11 ft. lbs. torque. Release tension and re-tighten to 3-5 ft. lbs. torque. While holding valve shaft nut against turning, tighten pilot lock nut to 5-10 ft. lbs. torque. After final tightening, use a fine punch and working through one of the small holes in the pilot lock nut, make a punch mark to stake lock nut to valve shaft. Install "O" ring seal on pilot lock nut. Remove two cap screws and nuts used to assemble valve body and shaft together. Install valve spring. Insert housing seal in the contoured ring groove in valve housing. Place power cylinder on valve assembly and install attaching screws(dip threads in sealer). (*CAUTION*—Do not gouge or slice pilot lock nut seal when assembling cylinder to valve assembly) Tighten valve housing attaching screws to 12-15 ft. lbs. torque. Install valve fittings and seals in their proper places. Assemble pressure and return hoses to their proper fittings on valve body assembly.

HYDRAULIC PUMP OVERHAUL: *See Vickers Pump data under "Vickers & Eaton Hydraulic Power Pumps"*

STEERING GEAR ADJUSTMENT & OVERHAUL: *See "Gemmer Worm & Roller"*

ROSS LINKAGE TYPE

Dodge V8 (1954)

DESCRIPTION: Ross "Hydrapower" hydraulic, linkage type power unit (power cylinder and control valve assembly). Power unit is an integral part of the steering linkage and transmits steering wheel motion to the wheels mechanically which permits manual steering when hydraulic power not available. Steering gear pitman arm is connected to spool valve in control valve assembly (bolted on side of power cylinder) with a reactor link extending from the opposite end of the control valve to a mounting bolt at opposite end of power cylinder. Two ball stud joints are mounted at center of reactor link for right and left tie rod connection. Spool valve is normally centered in valve housing (by spring at each end) so that pressures are equalized throughout the system. Whenever steering wheel pull exceeds 2 lbs. spool valve moves off center so that hydraulic pressure directed to one end of cylinder and other end opened directly to the reservoir. This causes the power cylinder to move in correct direction to provide power assistance. As soon as steering wheel pull drops below 2 lbs., spool valve returns to centered position and power assistance ceases.

Hydraulic Pump & Reservoir Assembly: "Single Rotor" type hydraulic pump and reservoir assembly mounted on generator. *See Hydraulic Pump data in "Gemmer Hydraguide" in Power Steering Section.*

►*ADJUSTMENT CAUTION: Whenever hydraulic system disturbed (by disconnecting lines, removal or installation of units, etc.) hydraulic system must be bled to remove air. See Bleeding Hydraulic System below.*

BELT ADJUSTMENT: *CAUTION–Pump is driven by fan belt and belt should be checked frequently and adjusted exactly as follows:* Use special tool C-3379 with a torque wrench. Hook tool over generator frame at the adjusting strap bolt lug, loosen strap bolts and bracket bolts, pull outward on torque wrench until indicated torque is 15 ft. lbs., tighten adjusting strap bolts before slackening off on wrench, tighten bracket bolts.

OTHER ADJUSTMENTS: No adjustments required in service.

►*STEERING GEAR ADJUSTMENT NOTE:* If steering gear chuck replaced due to accident or extremely high mileages, make check as follows: Remove chuck from vehicle. Torque required to rotate wheel (with scale pulled 90° to spoke of wheel at rim) when roller tooth (steering gear arm) shaft is not assembled in housing, should be 1-4 ozs. with no endplay in bearing. Then, after roller tooth shaft has been assembled, additional pull is required, making a total of 6-10 ozs. pull at rim to rotate steering wheel through mid-position, with no backlash in the worm and roller shaft at that point.

FRONT END ALIGNMENT: Same as for Manual Steering Gear. *See "Front Suspension" on Car Model Page.*

LUBRICATION: *CAUTION–Power Steering System and Steering Gear are lubricated separately and with different lubricants as follows:*

Power Steering System: Check fluid level in reservoir every 1000 miles, add fluid to maintain correct level. **Checking Fluid Level**–If dipstick provided in reservoir cover, maintain fluid level at mark on dipstick. If no dipstick provided, thoroughly clean top of reservoir, remove cover, maintain fluid level at least 1/2" above filter element in reservoir. Use SAE 10-W engine oil (5-W for temperatures consistently below 10°F).

Draining System–*CAUTION–Extreme care should be taken to prevent dirt from entering reservoir while cover is removed. To prevent damage to filter element, do not insert sharp objects into reservoir. Do not disturb filter element as periodic changes of this element are not required.* Disconnect high pressure (small) hose at booster. Place hose in suitable container. While holding hose in container start engine and allow to idle until all fluid is forced from unit. *(CAUTION–Do not run engine above idle speed).* As soon as fluid starts to show great quantities of air bubbles, stop engine. Reconnect high pressure hose.

Refilling System (after units removed or disconnected)–Fill reservoir to higher level than normal. Start engine and allow it to idle for short time to circulate oil through system. With engine idling, turn steering wheel through entire travel (from extreme right to extreme left) several times to bleed air out of system. Check oil level in reservoir, add oil as necessary. **Capacity**–3 pints.

Steering Gear: Same type as used on cars without power steering and lubricated similarly.

BLEEDING HYDRAULIC SYSTEM: With engine running at idle speed, turn steering wheel back and forth several times from extreme right to left to bleed any air out of system. Check oil level in reservoir. Add oil as necessary to bring level to "Full" mark.

TESTING: Should lack of steering assistance be encountered and other checks have been made (See Trouble Shooting below), a pressure check should be made to determine if pump is at fault.

Hydraulic Pressure Check: 1) Connect gauge C-3102 in pressure line between pump and hose with shut-off valve on gauge in open position. Start engine and turn steering wheel. If gauge does not show at least 400 lbs. pressure when steering wheel is in either extreme position, check pump by turning valve of gauge to closed position. If pressure does not gradually increase as valve is closed, flow control valve in pump may be stuck in open position, or drive coupling may be broken. See step 2) below. If 400 lbs. pressure does show on gauge with engine idling, pump is in good condition (Look for trouble as indicated in Trouble Shooting below). Remove gauge and connect high pressure hose to pump.

►*NOTE:* If gauge not available, a fairly accurate way of making test is as follows: Start engine and turn wheel to both extreme positions. If high pressure hose flexes, pump is in good condition. If high pressure hose does not flex, lack of pressure from pump is indicated. Shut off engine and check pump as follows: 2) Remove cover from reservoir, start engine and turn steering wheel. If oil flows through filter, a stuck flow control valve plunger is indicated. Shut off engine, remove high pressure hose at pump fitting and insert a 1/4" clean, blunt probe against valve plunger. If plunger moves inward 3/16-1/4", plunger was stuck and will probably function properly next time.

3) Recheck pressure. If it still registers less than 400 lbs. and if oil still flows through filter but does not flex pressure line, remove flow control valve plunger and clean thoroughly. If this does not correct condition, install a new pump assembly.

4) If oil does not flow through reservoir filter in above test, a broken coupling is indicated. Remove pump from generator. If either coupling is broken turn pump shaft by hand at least ten revolutions. If shaft turns freely, install new couplings on both pump and generator shafts. If pump shaft binds when turned by hand, replace both pump and couplings. If generator armature shaft is damaged, replace necessary parts. *(CAUTION–*Service package, Part No. 1450759 has been made available to prevent mixing of new coupling Part No. 1552859 with OTHER couplings in field). Reinstall pump on generator.

TROUBLE SHOOTING: *Diagnose trouble as follows:*

Hard Steering in Both Directions: Leak in system, pump belt slipping or broken, fluid level low, steering gear and linkage not lubricated, tire pressure too low, anti-roll bracket and pin binding, bend in power unit piston rod, low pump pressure, loss of pressure in power unit, insufficient fluid flow in system, bind in steering column or gear, improper front end alignment, valve in power unit sticking.

Smaller Turning Radius in One Direction: Wheel stops not adjusted properly.

Hydraulic Fluid Leaks (Locations): At hose adapters, pump body, valve assembly, valve spool assembly, reservoir cover gasket; around piston rod on power unit; between control valve body and cylinder head.

Hard Steering in One Direction Only: Tire pressure too low, bend in power unit piston rod, bind in steering column or gear, improper front end alignment, bind in control valve assembly.

Poor Recovery on Turns: Tire pressure too low, bind in valve assembly, bind in steering column or gear, bind in steering knuckles, bend in power unit piston rod, improper front end alignment, anti-roll pin and bracket binding.

Noise: Fan belt tension incorrect, low fluid level, pump shaft bearing worn, bushings worn in pump body or cover, dirt and sludge in pump, reactor link loose, tie rod clamps tightened in wrong position, steering gear arm adapter to valve spool loose or worn, steering gear arm nut loose, frame bracket cushion retainers striking frame bracket, position of clamp interfering with left tie rod.

REMOVAL & INSTALLATION: Proceed as follows:

Reactor Link Assembly (Unit in Car): Removal–Raise vehicle (preferably with hoist). Remove tie rods from reactor link assembly by removing cotter pins and nuts holding tie rods to threaded ends of the reactor link ball studs. Note position of clamp assembly (to prevent interference on turns), then loosen.

CONTINUED ON NEXT PAGE

ROSS LINKAGE TYPE
(Continued)

Remove reactor link-to-cylinder mounting bolt and lockwasher. Lift reactor link assembly over dowel ring (at mounting bolt end) and slide out of cover reducer end of control valve assembly. *NOTE–Dowel ring may remain in link or cylinder.*

Installation–Place dowel ring in position in cylinder. Install tie rod dust seals and lubrication fittings into reactor link assembly. Install clamp assembly (if removed), then slide reactor link assembly into cap reducer end of the control valve assembly, and position over dowel ring. Install mounting bolt and lockwasher, torque to 45-55 ft. lbs. Position clamp assembly for maximum clearance with tie rod ends, torque to 15-20 ft. lbs. Lubricate fittings and road test.

Power Steering Assembly: Removal–Raise vehicle (preferably on a hoist). Place drain pan beneath power unit at hose fittings, disconnect both hydraulic lines (pressure and return) from power unit. Remove tie rods from reactor link assembly by removing cotter pins and nuts which hold tie rods to threaded ends of the reactor link ball studs. Disconnect piston rod boot at frame bracket end. Holding flattened section of piston rod with 9/16" open end wrench, remove piston rod-to-frame bracket retaining nut. Remove outer linkage bracket cushion retainer and cushion, disconnect piston rod from frame bracket. *(CAUTION*–Booster unit should be prevented from dropping by either holding or tying in place). Disconnect steering gear arm from steering gear arm adapter by removing cotter pin and nut. *(CAUTION*–Tap on steering gear arm and not adapter stud). Remove unit. Then proceed with Bench Operation below.

Bench Operation–Remove piston rod cushion locator, cushion and inner cushion retainer from piston rod. Remove piston rod boot from piston rod bearing retainer. Carefully fold back rubber boot over anti-roll pin and bracket. Remove the two anti-roll bracket retaining nuts and lockwasher. Remove anti-roll bracket from valve and cylinder assembly. Remove anti-roll pin (stud), which clamps steering gear arm adapter to valve spool. Holding valve spool by flats provided for this purpose, remove steering gear arm adapter from control valve assembly by unscrewing adapter from threaded end of valve spool. Remove dust seal from threaded end of valve spool.

Installation–Reverse steps given in **Bench Operation** above. Install inner linkage bracket cushion retainer, cushion and cushion locator on piston rod. Place piston rod through frame bracket and install the cushion, outer retainer and nut. Holding piston rod by flattened section with 9/16" open end wrench, tighten nut to 55-65 ft. lbs. torque. Place steering gear arm adapter stud in steering gear arm and install nut–tighten to 55-65 ft. lbs. torque, replace cotter pin. Connect piston rod boot at frame bracket. Place tie rods on reactor link assembly ball studs and install nuts–tighten to 55-65 ft. lbs. torque, replace cotter pins. Install hydraulic lines to power unit assembly. Refill reservoir (see Lubrication above). It will be necessary to recheck front end and steering wheel alignment, if tie rods have been changed. (see (See "Front Suspension" on Car Model page). Road test.

OVERHAUL: *CAUTION*–Cleanliness through all phases ov overhaul cannot be overemphasized. Unit should be thoroughly cleaned in a suitable solvent when removed from vehicle. When disassembling, each part should be placed in the solvent, washed, then dried with compressed air. Careful handling of parts must be exercised to avoid occurence of nicks and burrs. Crocus cloth may be used to remove small nicks and burrs provided it is used carefully. When used on valve spool, **use extreme care not to round off the sharp edge portion. The sharp edge portion is vitally important to this type of valve.** It helps to prevent dirt and foreign matter from getting between valve and bore, thus reducing possibilities of sticking. Remove and discard all "O" ring seals, and seals, using new ones lubricated with Lubriplate when reassembling.

Disassembly of Power Steering Unit Assembly (Into Major Components): Note position (to prevent interference on turns) of clamp assembly on reactor link then loosen nut. Remove reactor link mounting screw and lockwasher and slide link assembly from end cover. Remove dowel from cylinder. Scribe a line across valve body and cylinder head to show position of parts when reassembled. *(CAUTION*–There is only one correct position of control valve on cylinder head which will permit proper alignment of the four oil passages. Should valve be incorrectly assembled, unit will not function). Remove the four valve body-to-cylinder head mounting bolts, nuts and lockwashers and separate valve body from cylinder. Note two different length bolts used. Power Unit is now set up into three serviceable items–Reactor Link Assembly, Control Valve, and Power Cylinder. Disassemble these components and inspect as follows:

Reactor Link Assembly–Assembly is self-contained unit. Check ball studs for wear. If studs are loose in ball sockets, replace reactor link assembly.

Control Valve–*NOTE*–Since this unit works in oil during operation, very little wear is anticipated on any of moving parts. The major component parts of valve are machined to very close limits and selectively fitted. Use extreme caution when handling these parts as damaged sealing edges or burrs will not permit unit to function properly. It is not practical to service valve body or spool separately. Because of their selective fit and difference in size, gland and reaction rings will be referred to as **Left** and **Right.** This identification has reference to position of parts relative to their position in the vehicle and **not** to the direction of steering wheel turn. These parts are not interchangeable. **Always note their position when disassembling** so their position is not changed when reassembling. The largest gland and reaction ring are the parts for the left side and **must** be installed in the steering gear arm end of the valve. Glands and reaction rings are serviced in matched sets. Disassemble as follows: Using screwdriver or punch, unlock end cover caps by straightening lock ring tabs. Unscrew and remove both end covers from valve body. *(CAUTION*–Use extreme care so as not to damage mating surfaces on valve body when removing caps. Also the use of a strap wrench will prevent damage to exterior finish of caps). Remove lock rings. Remove right gland and spring by slightly pushing on threaded end of valve spool. Remove "O" ring from end of valve spool (end from which gland was just removed). Remove left gland and spring by pulling on threaded end of valve spool. When removing spool, one reaction ring will probably remain in valve body and can easily be removed. The other ring remains on spool. Remove remaining "O" ring and reaction ring from valve spool. Match reaction rings with their respective glands. Remove "O" rings from glands.

Inspection–Since very little wear is contemplated on any of moving parts of control valve, the only parts that may need replacement, in addition to "O" rings, are centering springs, lock rings, and occasionally an end cover or clamp assembly. Inspect valve spool and bore for nicks, burrs, and scoring. If used carefully, crocus cloth may be used to remove slight score marks. *CAUTION–Do not round off sharp edge portion of spool when using crocus cloth.*

Cylinder–Drain oil from cylinder assembly by moving piston rod in and out from one extreme end of its travel to the other. Remove four "O" ring seals from cylinder head. Note position of piston rod bearing retainer snap ring in end of cylinder (retainer locks snap ring into position). Using punch, straighten tang on retainer and remove snap ring with tool C-3106. Remove piston, rod, bearing and seal assembly from cylinder. *(CAUTION*–Do not clamp or mark sealing surface of piston rod as damage will result to seals. When removing parts from piston rod, always slide them off piston end of rod). Holding piston rod at flattened section at frame bracket end of piston rod, remove cotter pin, nut and backup washer (steel). Remove piston and rings, piston rod bearing, and "O" ring seal from outer diameter of bearing. Remove oil seal from inside of bearing. Remove piston rod bearing backup washer (steel). Remove plastic shims (Note number removed). Slide piston rod seal retainer and spline seal from piston rod.

Inspection–Inspect all parts closely for damage and wear. Check for nicks, burrs, and scores. Crocus cloth may be used (carefully) to remove slight nicks, burrs, and scores.

Reassembly: *(CAUTION*–Be sure all parts washed in suitable solvent and dried with compressed air. Use new "O" rings, seals. Use extreme care in handling parts to avoid damaging sealing edges or causing burrs). Reassemble components on Steering Gear Unit Assembly as follows:

Control Valve–Lubricate valve spool with SAE 10W engine oil, then with twisting motion slide spool (threaded end toward steering gear arm) into valve body. Push spool through body sufficiently to install

CONTINUED ON NEXT PAGE

ROSS LINKAGE TYPE
(Continued)

right reaction ring (check marks made during disassembly for identification). Lubricate new "O" ring seal with Lubriplate and install on valve spool. Install left reaction ring on threaded end of valve spool followed by a new "O" ring seal lubricated with Lubriplate. Place springs (one on each end) into position in valve body. Lubricate new "O" ring seals with Lubriplate and install on glands. Install glands (identified as right and left at disassembly) into their respective positions in valve body. Position lock rings over threaded ends of valve body. *(CAUTION*–Make sure tangs on lock rings mate with grooves on valve body). Start end cover reducer (one with clamp assembly) on valve body (opposite threaded portion on valve spool), then start other end cover, draw down evenly and tighten. Using small punch and hammer, stake lock rings to end cover and reducer. *CAUTION*–Use extreme care so as not to damage mating surfaces on valve body when installing end covers.

Cylinder–*(CAUTION*–It is suggested that assembly be made from piston end of rod to prevent damage to any of parts). Lubricate new splined seal with Lubriplate and install in retainer, (tapered side of seal to correspond with concave of retainer). Slide splined seal and retainer (seal side of retainer up, so it faces to inside of cylinder down on to piston rod). Install plastic shims (same number as removed). *(NOTE*–The number of shims used will vary. They may also be added or removed without completely disassembling cylinder by cutting and placing them around piston rod. These shims are used to control the amount of end play between piston rod bearing retainer snap ring and bearing seat in cylinder. A maximum of .005" end play is permissible after shimming. Shims available .005", .010", .015" thick). Install piston rod bearing backup washer (steel). Using a vise with protective jaws, press new seal (lip of seal first) into piston rod bearing. Lubricate new "O" ring seal with Lubriplate and install on outer diameter of piston rod bearing. Slide piston rod bearing assembly (seal end first) onto piston rod. Install piston rings on piston, making sure they are free to rotate in glands. Install piston and backup washer (steel) on piston rod. (NOTE–Inside of piston tapered). Install nut (castle), then holding piston rod by flats provided on opposite end, use tool C-3005 and tighten nut to 35-45 ft. lbs. torque. (CAUTION–Always use torque wrench to avoid any possibility of over-tightening which might cause piston to swell and prevent assembly entering cylinder). Install cotter pin. Lubricate piston rings with Lubriplate and stagger ring gaps. Use extreme care, insert piston and rod assembly into cylinder, compressing rings with fingers. Push assembly gently (to insure compressing rings and avoid scoring of cylinder wall) into cylinder as far as it will go. Position piston rod bearing retainer in cylinder (opening in snap ring to line up with tang on retainer and hole in cylinder) and install snap ring. Make sure snap ring is seated properly. Check end play between retainer and snap ring, if .005" or less use punch and lock retainer in place. If more than .005" end play exists unit will have to be disassembled sufficiently to permit plastic washer of greater thickness to be installed. Move piston rod in and out of cylinder to make sure it does not bind. Cylinder and control valve can now be assembled.

Cylinder & Control Valve–Lubricate new "O" ring seals (4) with Lubriplate and position around oil passages on cylinder head. Check markings on control valve and cylinder head, then position valve on head. *(CAUTION*–Make certain oil passages in control valve housing match those in cylinder head). Install four mounting bolts, lockwashers and nuts. *(CAUTION*–*DO NOT TIGHTEN NUTS.* The two long bolts are used in the outer holes adjacent to threaded end of valve spool for retaining anti-roll bracket). Install tie rod dust seals and lubrication fittings (if removed) into reactor link. Place clamp assembly on end cover reducer (if removed) and install dowel ring in cylinder casting. Install reactor link into end cover reducer and position other end of link over dowel. Install reactor link mounting bolt and lockwasher. Draw four control valve mounting bolts down evenly, then, using tool C-3005, tighten to 15-20 ft. lbs. torque. Using tool C-3005, tighten reactor link mounting stud to 45-55 ft. lbs. torque. *(CAUTION*–Tightening in above manner assures alignment between control valve and reactor link mountings). Position clamp assembly for maximum clearance with tie rod, then tighten to 15-20 ft. lbs. torque. Install dust seal over threaded portion of valve spool and down against end cover. Holding valve spool by means of flats provided for this purpose, screw steering gear arm adapter onto valve spool until it bottoms against end of threaded section of spool. Install anti-roll stud, then place anti-roll boot over anti-roll stud and fold back to install anti-roll bracket, tighten bracket retaining nuts to 15-20 ft. lbs. torque. Check alignment of anti-roll stud in slot of anti-roll bracket. The centerline of stud should be approximately in the center of the slot. The center of the barrel section of the anti-roll stud should line up with the mid point of the thickness of the bracket. A standard flat washer may be added, if necessary, beneath anti-roll stud shoulder to obtain this alignment. Fill anti-roll boot with chassis lubricant and snap into position on bracket. Install piston rod boot over piston rod bearing retainer. Power Steering Unit Assembly is now ready for installation in car (See Steering Gear Installation above).

HYDRAULIC PUMP REMOVAL & INSTALLATION: *See "Hydraulic Pump Overhaul" under "Gemmer Hydraguide"*

HYDRAULIC PUMP OVERHAUL: *See "Hydraulic Pump Overhaul" under "Gemmer Hydraguide"*

FORD & MERCURY BENDIX POWER STEERING

Ford, All Models (1953-55)
Thunderbird (1955)
Mercury, All Models (1953-55)

▷CHANGES, CAUTIONS, CORRECTIONS

▷*1953 FORD SPINDLE CONNECTING ROD END CLAMP INSTALLATION CAUTION:* Left hand spindle connecting rod end must be installed on sleeve with ears on forward side of connecting rod and bolts in a vertical position. This position will prevent interference of ears with centering spring cover.

▷*PUMP ROTOR SHAFT BEARING REPLACEMENT CAUTION:* When replacing power steering pump rotor shaft bearing, use only replacement bearing 7RA-10094-A with neoprene grease retaining seal. Do not use bearing 7RA-10094-B with nylon grease retaining seal. Tests show that operating conditions in pump cause nylon seal to wrinkle and become rigid, allowing bearing grease to escape. Neoprene seal does not react this way and provides better sealing conditions.

▷*1954 FORD 6 CYL. PUMP LEAKAGE CORRECTION:* To minimize leakage at unused return port on pump, a plug (B4A-3569-A) and gasket (B4A-3592-A) are available for service and should be used to replace cup type plug used on earlier models if leakage is encountered.

▷*1955 FORD PRESSURE CHECK GAUGE ADAPTER KIT CHANGE:* Due to pump design change in May, 1955 it is necessary to use new adapters for pump fittings. Fittings can be made up using 5/8" inverted male connector (87974-S), 2¼" inverted female connectors (87200-S), 3⅝" inverted flare nuts (87953-S), a 5/8" short nut (87424-S), a 5/8" male connector (87234-S) and two pieces of soft copper tube 2½" long, 3/8" O.D.

▷*1955 MERCURY PUMP PRODUCTION CHANGE:* New pump differs from earlier type in that return port has been moved from pump body to a position on side of reservoir near bottom. Adapter, No. 3500-C must be used with Pressure Check Gauge No. 3500 when checking pressures. See Ford Pressure Check Gauge Adapter Kit Change (above).

▷*1953-55 MERCURY POWER CYLINDER & CONTROL VALVE REPAIR KITS:* The following repair kits are available for power cylinder and control valve repair: Drag Link Ball Stud Repair (MDK-3312-C), Power Steering Cylinder Seal (B3A-3315-A), Control Valve Seals (B3A-3316-A), Control Valve Centering Spring Repair (B3A-3317-A).

DESCRIPTION: Ford and Mercury "Linkage Type" Power Steering has its power mechanism built into the steering linkage (or attached to it) and is used in conjunction with a standard steering gear (with special ratio to take care of added power). Power steering system consists of the following units:

Hydraulic Pump & Reservoir Assy.—Mounted on engine and belt-driven from crankshaft. Consists of an Eaton rotor type pump with a built-in Relief Valve (pre-set to 700-900 psi.) and Flow Control Valve (limits maximum volume at high engine speeds to steering gear requirements).

Control Valve—Spool type valve located in end of steering drag link with valve spool directly con-

CONTINUED ON NEXT PAGE

FORD & MERCURY (C nt.)

nected to pitman arm. Valve is actuated by pitman arm (when steering wheel turned) and directs fluid pressure to one end of power cylinder and at same time vents the opposite end of the cylinder to the reservoir. Control valve also has a ball check valve in a by-pass passage in the valve housing to permit manual steering with power off.

Power Cylinder—Double-acting piston type. Piston rod is anchored to frame side rail and cylinder is connected to drag link so that power application tends to move the drag link in the same direction in which it is being moved by the steering wheel.

ADJUSTMENT: Proceed as follows:

►***ADJUSTMENT CAUTION—Whenever hydraulic system disturbed (by disconnecting lines, removal or installation of units, etc.) hydraulic system must be bled to remove air. See Bleeding Hydraulic System below.***

Pump Drive Belt Adjustment: Check tension of the pump belt by having another person bring wheels against stop and hold for a few seconds. Observe if pump pulley slows down or stops. If it does a loose belt is indicated. Belt tension should be 5-7 lbs. with ¼" deflection at center of belt.

►***1954-55 FORD V8 & THUNDERBIRD PUMP BELT ADJUSTMENT NOTE:*** To prevent slippage of belt on hard right and left turns, belt must be adjusted so that torque of 14-16 ft. lbs. is required to slip pulley against the belt tension. To check, install a torque wrench on pump pulley-to-rotor shaft bolt and check torque required to slip the pulley. If torque is not 14-16 ft. lbs., install a 2½" heavy duty "C" clamp so end of clamp is positioned against lower edge of pump-to-cylinder head bracket, and screw of clamp is against top edge of movable pump bracket. Loosen the four attaching bolts and tighten "C" clamp screw to increase belt tension to obtain a torque of 14-16 ft. lbs., required to slip pulley against belt. Tighten pump attaching bolts and remove "C" clamp.

LUBRICATION: ***CAUTION—Power Steering Unit and Steering Gear are lubricated separately with DIFFERENT lubricants as follows:***

Power Steering System: Maintain fluid level in reservoir at full mark as indicated on dipstick. Use Automatic Transmission Fluid Type "A".

Steering Gear: Check at 1000 mile intervals. Keep filled to level of filler plug with SAE 90 Mild EP. gear oil.

BLEEDING HYDRAULIC SYSTEM: Fill reservoir to full mark (indicated on dipstick) with Automatic Transmission Fluid Type "A." Start engine and run at idle speed for two minutes. Recheck fluid level and inspect hose connections for leaks. Increase engine speed to 1000 RPM. and turn wheels from right to left five or six times. DO NOT HIT STOPS. Recheck for leaks. Check oil level and refill as required.

TESTING: When operation of the system is unsatisfactory and before performing any tests be sure pump belt tension is correct, fluid level is proper, and oil leaks eliminated. Before testing Power Steering unit be sure that wheel alignment, pressure and condition of tires and shock absorbers are satisfactory. Then make tests as follows:

Steering Effort: Set the hand brake, start engine, and rotate steering wheel to left and right to warm up oil. DO NOT turn wheel to limit of its travel (to prevent unnecessary strain on system). Hook 15 lb. scale to rim of steering wheel and measure the pull it takes to turn wheel. If pull on the wheel is between 7 and 12 pounds, on a dry concrete floor with engine at idle speed, unit is working properly.

Hydraulic Pressure: First remove the pressure hose from pump, connect gauge between pressure fitting on pump and pressure hose that leads from pump to power unit. Let engine idle until oil reaches operating temperature. Then turn wheel for a full right or full left turn. The gauge should read between 700 and 900 psi. If pressure less than 700 psi., close the valve at gauge and note pump pressure. If low with valve closed, pump is not operating properly. If pressure goes up with valve closed, it indicates that low pressure in system is due to internal leakage in power unit, providing all connections are tight.

TROUBLE SHOOTING: ***Diagnose trouble as follows:***

Sticky Feeling Off-center, or Poor Recovery:
1) Steering wheel bind at steering column, or steering gear shaft bind in column; steering linkage bind.
2) Excessive gear mesh preload.
3) Interference of pitman arm and valve sleeve at ball stud connection or of ball stud in T-slot of valve sleeve; ball stud adjustment too tight; damaged sleeve.
4) Valve spool bolt adjustment too tight or binding valve spool.
5) Excessive break away friction of cylinder rod seal.

Excessive Free Play or Lost Motion in Steering:
1) Improper sector shaft or mesh preload.
2) Improper adjustment of valve sleeve ball, or valve spool.
3) Excessive play in steering linkage or excessive negative caster.
4) Defective valve center spring.

Loss of Power Assistance: 1) Inoperative pump or damaged or leaking lines.
2) Internal parts of power cylinder broken or damaged.
3) Extreme maladjustment of valve spool.

Loss of Power Assistance—In One Direction Only:
1) Incorrect adjustment of valve spool in valve.
2) Inoperative by-pass check valve.

Oil Leaks: 1) Loose or damaged hose connections.
2) Leaking valve or cylinder seals.
3) Loose or defective cylinder bleed line or fittings.

Hard Steering: 1) Low pump output.
2) Improper gear mesh preload, lubrication. valve spool adjustment, or ball stud adjustment.
3) Excessive valve or cylinder leakage; sticky valve; loose cylinder housing.
4) Linkage bind.

REMOVAL & INSTALLATION: Proceed as follows:

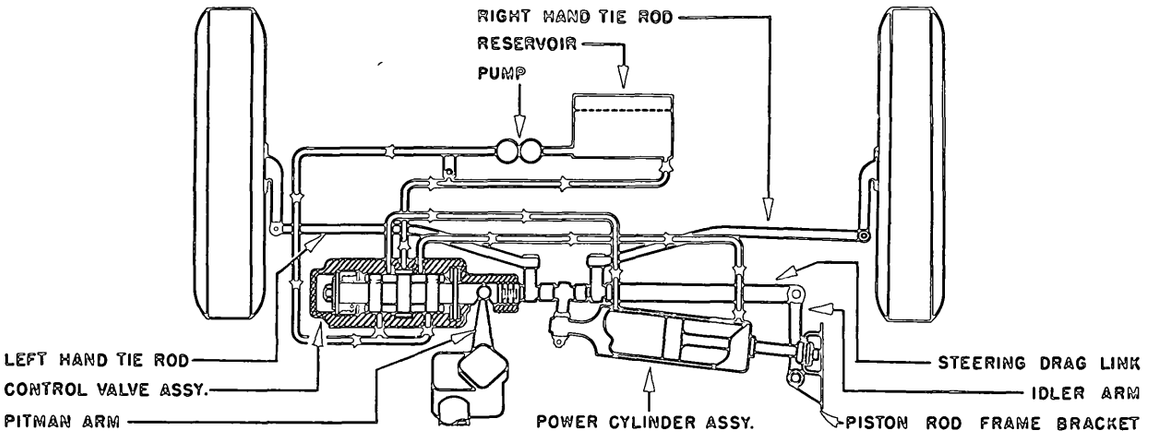
Control Valve: Removal—Remove the filler cap from reservoir, with suction gun remove as much oil as possible from reservoir. Raise car on hoist and drain remaining fluid by disconnecting valve-to-cylinder hoses at valve (to insure complete drainage, move wheels to left and right several times). Disconnect pressure and return lines from valve, drive locking pin up into steering arm rod just far enough to clear threads. ***CAUTION—Do not drive pin all the way into rod as damage to threads on opposite side of valve will result.*** Loosen sleeve clamping bolt. Remove cotter pin and nut that retain pitman arm to ball stud of valve, loosen pitman arm on stud using remover tool. Raise valve and move ball stud forward to clear pitman arm. Turn wheels to full left turn, then turn valve counterclockwise to remove valve from steering arm-to-idler arm rod. Drive roll pin completely out of steering arm rod.
Installation—Screw valve clockwise on steering arm rod until approximately four threads are showing on rod. Install ball stud in pitman arm and check distance between ball stud of valve and inner ball stud on left steering spindle arm connecting rod. (See table below for dimensions). Adjust valve, clockwise to reduce distance and counterclockwise to increase distance, until desired dimension obtained. Line slot in sleeve with hole in steering arm rod, lock valve in this position with locking pin. Tighten sleeve clamp bolt to 30-35 ft. lbs. (Ford), 25-30 ft. lbs. (Mercury). Install ball stud nut and tighten to 50-60 ft. lbs. (Ford), 60-65 ft. lbs. (Mercury), lock nut with cotter pin. Install pressure and return lines. Install short valve-to-cylinder hose first, with tube end of hose toward cylinder. This hose is installed in forward hole of cylinder and lower hole of valve. Then install longer hose with tube end toward cylinder, in rearward hole of cylinder and upper hole of valve. Lower car, then visually check straight ahead position of steering wheel. Make necessary adjustment of steering wheel or front wheels at tie rod ends. Check toe-in and correct, if necessary. Fill reservoir and bleed system (See Bleeding Hydraulic System). Check steering effort (See Steering Effort under Adjustments).

Car Model	Ball Stud Dimension
1953 Ford & Mercury	5⅛"
1954-55 Ford & Mercury	9"
1955 Thunderbird	9 9/16" ± 1/32"

Power Cylinder Assembly: Removal—First remove the filter cap from reservoir and with suction pump drain as much oil as possible from reservoir. Raise car on hoist, drain remaining fluid by disconnecting valve-to-cylinder hoses at cylinder (to insure complete drainage of system move wheels right and left several times). Remove palnut and nut that secure piston rod to mounting bracket on frame. Remove cup washer and rubber bushing. Next, remove palnut and nut that secures cylinder to stud on idler arm rod. Remove cup washer and rubber bushing, remove cylinder.
Installation—Place cup washer and rubber bushing on piston rod, insert piston rod through hole in frame bracket. With low pressure seal bleed line at top and forward of cylinder, place end of cylinder on steering pitman-to-idler arm rod stud. ***CAUTION: With cylinder in position on car, low pressure seal bleed line must be at top and forward of cylinder.*** Place rubber bushing and cup washer on steering pitman to idler arm rod stud. Install nut and tighten until it bottoms. Install palnut finger tight plus 1/3 turn. Place rubber bushing and cup washer on piston rod. Install nut and tighten until it bottoms. Install palnut finger tight plus 1/3 turn. Install valve to cylinder hoses, short hose in forward hole of cylinder, long hose in rear hole. Fill reservoir and bleed system (See Bleeding Hydraulic System).

Reservoir & Pump Assembly: Removal—First remove the filler cap and with a suction pump remove as

C NTINUED N NEXT PA E



FORD & MERCURY (Cont.)

much oil as possible from reservoir. Disconnect hoses at unions on pump assembly, place ends of hoses in raised position to prevent drainage of oil. Loosen belt tension bolt, remove pump belt. Remove pivot cap screw and adjustment bolt that secure pump mounting bracket to engine bracket. Remove reservoir, pump and pump bracket as an assembly. Installation—Reverse removal procedure (above). Torque pivot screw to 20-25 ft. lbs., hose fittings to 35-50 lbs. Adjust belt tension (See Adjustments). Torque tighten belt adjusting bolt to 20-25 ft. lbs. Fill reservoir and bleed system (See Bleeding Hydraulic System).

CONTROL VALVE OVERHAUL: Disassembly—Install brass jaws on vise, place valve in vise. *CAUTION—Do not tighten vise too tightly.* Cut and remove safety wires located at each end of valve housing, remove two cap screws that secure centering spring cover to valve body, then remove centering spring cover. Remove spool adjustment nut, small washer, large washer, centering spring, spring spacer, and large washer. Remove adapter plate and seal retainer. Remove two cap screws that secure sleeve and ball stud assembly to valve housing, remove sleeve and ball stud from valve housing. Remove valve spool from housing by pressing spool toward spool adjustment end of housing, remove seal from spool. Remove retainer spacer, bushing, and seal from sleeve end of valve housing.

Cleaning & Inspection: Wash all parts in suitable solvent, wipe dry with clean lint-free cloth. Check condition of all parts. Inspect valve spool to be sure it is free from burrs and not scored or damaged in any way. Remove burrs by carefully using fine crocus cloth. *CAUTION—Do not round sharp corners of spool.* Inspect valve housing for burrs, scored, or damaged condition. Remove burrs by carefully using fine crocus cloth. If check valve needs replaceing proceed as follows: Remove return line fitting seat by tapping existing hole in seat with 3/8" starting tap. Remove all tapping chips. Using 3/8" bolt, a large washer (large enough to fit over port), and a nut as a puller tool, remove fitting seat. Remove check valve retainer with screw driver, remove spring and ball. Inspect and replace defective parts, then install ball, spring, and valve retainer. Place fitting seat in place in port. Screw a 5/8"-18 bolt in port, and tighten sufficiently to seat fitting seat. All fitting seats in valve housing except pressure line port can be removed at outlined above. Pressure port has smaller diameter seat hole (3/16").

Reassembly: Put light film of Automatic Transmission Oil Type "A" on spool and slide spool, while rotating, into housing. *CAUTION—Install spool with large diameter end of spool toward small end of housing.* Lubricate and install small seal over small diameter end of spool. With small screwdriver CAREFULLY work seal into housing. Install bushing and retainer spacer in sleeve end of housing, seat retainer spacer in housing. Lubricate and install large seal over large diameter end of spool and CAREFULLY work seal into housing. Install adapter plate on small end of valve housing, check valve spool for freedom of movement. Install valve bolt of sleeve and ball stud assembly through spool in valve housing. Position sleeve so that ball stud is in line with three ports in valve housing. Install two cap screws and tighten to 25-30 ft. lbs. torque. Install large washer, spring spacer, large washer, and small washer on valve bolt. Compress spring and install adjusting nut. Tighten nut until solid, then back off 1/4 turn. Check valve spool for freedom of movement, by moving ball stud back and forth along sleeve. Movement should be approximately .060" travel. Install centering spring cover and retain with two cap screws, tighten to 12-15 ft. lbs. torque. Install locking wire between two centering spring cover cap screws, similarly between sleeve cap screws. NOTE—Lock wire on sleeve cap screws should be located on side opposite from dust shield. Check freedom of movement of valve by installing castle nut on ball stud and placing nut in vise. Actuate valve by pushing center spring cover end of valve housing toward ball stud. Then rotate valve 180° and push sleeve end toward ball stud.

FORD & MERCURY "LINKAGE TYPE" POWER STEERING SYSTEM

POWER CYLINDER ASSEMBLY OVERHAUL: Construction of power cylinder is such that repair of piston and rod is not feasible. If failure of cylinder occurs, it must be replaced as a complete assembly. However, seal and scraper at piston rod end of cylinder can be replaced if there is indication of leakage (see below). Bleed line can be replaced if damaged. Fitting seats located in ports at end of cylinder can also be replaced (see below).

Cylinder Rod End Seal Replacement—Remove cylinder from car (see Removal above). Place end of cylinder in vise, clamping on eye end, remove snap ring from cylinder rod end with special pliers. Remove scraper by pulling piston rod outward. If scraper does not come out in this manner use a prick punch. Remove seal using prick punch. Lubricate new seal, install seal and scraper. Seat seal and scraper using a 7/8" deep well socket, install lock ring. Install cylinder on car (see Installation above).

Replacement of Fitting Seats—Remove cylinder from car (see Removal above). Tap existing hole in seat using 3/8" starting tap. *CAUTION—Be sure all chips are removed after tapping.* Using a 3/8" bolt, a large washer (larger enough to fit over port) and a nut as a puller tool, remove fitting seat. Place fitting seat in place in port, screw a 5/8"-18 bolt in port, then tighten sufficiently to seat fitting seat. Install cylinder on car (see Installation above).

SLEEVE ASSEMBLY OVERHAUL: Disassembly—Place stop screw in vise, pull valve bolt out from sleeve to take up slack, drive pin from stop screw. Remove sleeve from stop screw by turning sleeve counter-clockwise. Remove valve bolt from stop screw, then remove dust shield. Move ball stud toward enlarged portion of hole in sleeve, remove ball stud, socket tube, plug, springs, and ball stud seats.

Cleaning & Inspection: Wash all parts in suitable solvent, wipe dry with clean lint-free cloth. Inspect condition of each part, replace any damaged parts.

Reassembly: Place ball stud seats, spring, plug and socket tube in sleeve housing. Insert ball stud through enlarged opening of sleeve housing. *CAUTION—Be sure ball joint seats are properly aligned.* Install stop screw with valve bolt in place. Tighten screw until solid, then back off to nearest hole. Align slot in valve bolt head with hole in stop screw, install pin. Install dust shield.

PUMP OVERHAUL: *See Eaton Pump data under "Power Steering Hydraulic Pumps" for complete data.*

STEERING GEAR ADJUSTMENT & OVERHAUL: *See "Gemmer 305, 335, 375" Steering Gears for complete data.*

STEERING LINKAGE: *See "Steering Linkage."*

BENDIX POWER STEERING

Nash Ambassador 6 (1953-55)
Packard, All Models (1953-54)
Packard, Series 5560, 5580 (1955)

DESCRIPTION: This "Linkage Type" Power Steering differs from other types in that the power mechanism is built in the steering linkage (or attached to it) and is used in conjunction with a standard steering gear (gear has special ratio to take advantage of added power). Power steering system consists of the following units:

Hydraulic Pump & Reservoir Assy.—Mounted on the engine and belt-driven from the crankshaft. Consists of an Eaton rotor type pump with a built-in Relief Valve (pre-set to specified limits—See Testing Hydraulic Oil Pressure below) and Flow Control Valve (limits maximum volume, at high engine speed, to steering gear requirements.

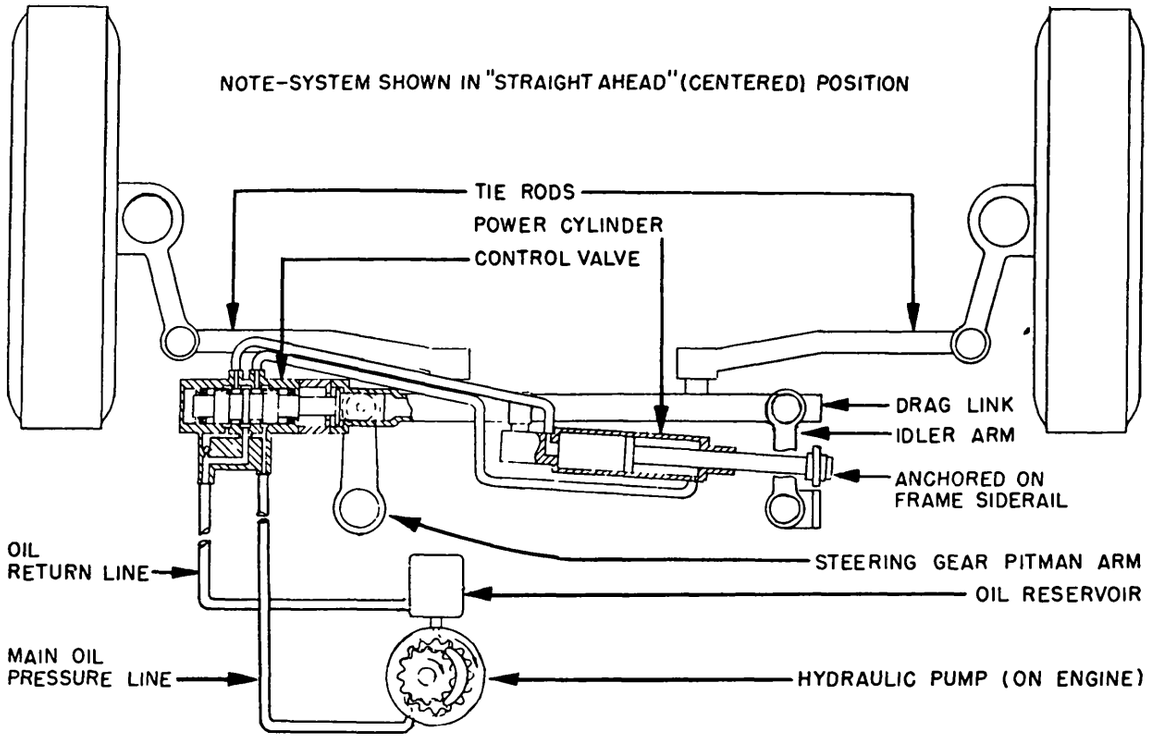
Control Valve—Spool type valve located in end of steering drag link with valve spool directly connected to pitman arm. Valve is actuated by pitman arm (when steering wheel turned) and directs fluid pressure to one end of the power cylinder and at the same time vents the opposite end of the cylinder to the reservoir. Control valve also has a ball check valve in a by-pass passage in the valve housing to permit manual steering with the power off.

Power Cylinder—Double-acting piston type. Piston rod is anchored to frame side rail and cylinder is connected to the drag link so that power application tends to move the drag link in the same direction in which it is being moved by the steering wheel. Cylinder is double-acting (with fluid pressure in one end of cylinder, opposite end is vented to the reservoir through the control valve).

PUMP DRIVE BELT ADJUSTMENT: (Nash) Adjust pump drive belt sufficently tight to prevent slippage. (Packard) Adjust belt to 26-28 ft. lbs. torque. Make certain belt pulleys are in alignment.

►***ADJUSTMENT CAUTION—Whenever hydraulic system disturbed (by disconnecting lines, removal or installation of units ,etc.) hydraulic system must be bled to remove air. See Bleeding Hydraulic System.***

LUBRICATION: ***CAUTION—Power Steering System and Steering Gear are lubricated separately and with DIFFERENT lubricants as follows:***



Power Steering System: Check fluid level in reservoir at 1000 miles intervals (remove reservoir cover). Maintain level at 1" below top edge of reservoir. Use recommended fluid as follows:
Nash—Hydra-Matic Transmission Fluid (Automatic Trans. Fluid Type A in "AQ-ATF" container).
Packard—Ultramatic Drive Fluid (if not available, use Automatic Trans. Fluid Type A).

Steering Gear: Check lubricant level every 3000 miles and maintain even with filler plug hole. Use SAE. No. 90 Steering Gear Oil.

BLEEDING HYDRAULIC SYSTEM: Whenever lines disconnected, or units disturbed, bleed system by making complete right and left power turns, then recheck oil level in reservoir.

TROUBLE SHOOTING: ***If operation not satisfactory, diagnose trouble as follows:***

HARD STEERING: 1) Pump failure, loose or broken belt.

NASH & PACKARD "LINKAGE TYPE" POWER STEERING SYSTEM

2) Broken or weak relief valve spring, sticking relief valve.
3) Low pump pressure, line leakage, or low fluid in system.
4) Under-inflated tires.
5) Bent linkage, steering tube mis-alignment, improper wheel alignment.
6) Steering adjustment tight.
7) Improper lubrication.
8) Leakage in power cylinder past piston ring.
9) Air in system.
10) Pump control valve sticking.
11) Control valve spool out-of-round or damaged.

STEERING TOO SENSITIVE: 1) Overinflated tires.
2) Pump pressure too high.
3) Flow control valve stuck in closed position.

LOOSE STEERING: 1) Wheels out of alignment, bearings loose or worn.
2) Loose ball joints, steering knuckle pins, steering gear-to-frame bolts, pitman arm, or lash in linkage.
3) Air in system.

POOR CENTERING: 1) Faulty or binding control valve spool or power cylinder.
2) Control valve spool nut too loose or too tight.
3) Steering misalignment, one tire underinflated, loose wheel bearings.

POOR RECOVERY: 1) Steering gear adjusted too tight, improper caster adjustment.
2) Lack of lubrication of linkage, low tire pressure.
3) Stop nut pin installed in wrong hole causing spool assembly to bind in bore.

PUMP NOISE: 1) Improper fluid level, loose return hose connection, clogged intake line or filter, improper fluid.
2) Pump belt squeal, hose rubbing against other parts, loose pulley, mechanical trouble in pump, relief valve chattering.
3) Wheels held at stops too long, overheating pump.

LOW PRESSURE (When Tested With Gauge):
1) Low fluid level, external or internal leakage.
2) Slipping belt or pump mechanical trouble.
3) Pump relief valve weak or stuck open, flow control valve struck open.

NO POWER ON STEERING GEAR (Engine Running): 1) No pressure at pump. Items 1) to 3) for Low Oil Pressure (above) apply.

CHUCKLE OR RATTLE IN STEERING: 1) Too much back lash in steering, worn or loose parts, ball socket or studs loose.
2) Control valve improperly adjusted.

SHIMMY: 1) Lash in linkage, worn or loose steering parts, wheels out of balance.

OIL LEAKS (PUMP): 1) Loose or defective connections, defective "O" ring seals between reservoir and pump, or between connections.

CONTINUED ON NEXT PAGE

BENDIX POWER STEERING (Cont.)

2) Defective seal on pump shaft or between cover and body, hose leaks.

OIL LEAKS (POWER CYLINDER): 1) Loose or defective connections.
2) Defective seals between cylinder flange and body.
3) Defective spring loaded metal encased seal on shaft, scored shaft.

OIL LEAKS (CONTROL VALVE): 1) Worn seals on end of spool.
2) Drippage of fluid from ball stud section indicates seals on spool are passing fluid.

CONTROL VALVE NOISE: 1) Spool bolt nut loose, causing spool flutter.

STEERING WHEEL DOES NOT CONTROL OPERATION OF POWER STEERING (After Assembly To Car): 1) Improper hose connections.

TESTING HYDRAULIC OIL PRESSURE (NASH): Check reservoir for correct fluid level. If low, fill to proper level with Hydra-Matic Transmission Fluid. Inspect all hoses and connections for evidence of external leaks. Test as follows:

(1) Install Oil Pressure Gauge J-5548 in main oil pressure line at control valve. Start engine, allow oil to circulate for several minutes to warm oil in reservoir.

(2) With car standing on dry, rough concrete, make complete turn in each direction. Observe oil pressure gauge during this operation. Gauge should indicate 450-550 P.S.I. If oil pressure low, pump operation or oil leakage is cause. If pressure varies more than 100 P.S.I. in either direction, internal leakage is cause.

(3) Check oil pump pressure output and relief valve operation by disconnecting pressure gauge from control valve and capping pump pressure line so pump will develop maximum pressure. Plug control valve to prevent excessive oil loss. With engin. idling, gauge should indicate 700-900 P.S.I. If pressure low or erratic, pump belt may be loose. Watch pump pulley for smooth operation. If pump belt not slipping pump is at fault.

(4) After pump checked and operation satisfactory, reconnect gauge to control valve, disconnect two lines to power cylinder, plug two ports in control valve using special plugs. With engine idling, steer car in both directions observing pressure. Pressure should be 700-900 P.S.I. If pressure low turning one way and correct the other, inspect control valve spool spacer sleeve for correct length (41/64"). Low pressure turning both ways indicates internal leakage in control valve.

(5) If pump pressure check and inspection of control valve shows both units operating satisfactorily, then power cylinder is cause of the difficulty.

TESTING HYDRAULIC OIL PRESSURE (PACKARD): Remove reservoir clamp, cover and gasket. Using suction pump, remove oil from reservoir. If suction pump not available, disconnect pump hose at control valve and drain oil from pump. If last method used, after oil drained, reconnect and tighten hose to control valve. Test as follows:

(1) Disconnect pressure hose at union on right side of pump, install pump pressure Gauge Hose and Valve PK-13 on union at pump with hand valve open. Connect pressure hose to fitting on hand valve side of gauge. Refill reservoir to proper oil level.

(2) Run engine until warmed up, then turn wheels from full right to full left position to bleed air from system. Add oil as required to bring fluid to proper level. After engine warmed up and idled at 375 RPM., wheels should be resting on ground in straight-ahead position. Close gauge hand valve and observe gauge reading. Reading should be approximately 650 P.S.I. Gauge will oscillate several hundred P.S.I. on gauge dial. Center reading will be approximately 650 P.S.I. if pump at maximum efficency. If average reading below 550 P.S.I. pump needs repair. *CAUTION—Do not keep gauge hand valve closed any longer than necessary to read gauge.*

(3) Turn steering wheel toward either of wheel stops. As wheel is turned from straight-ahead position, pressure will start increasing until it reaches wheel stops where pressure should be 600-650 P.S.I. If pressure less than 600 P.S.I. trouble lies in control valve or power cylinder.

(4) After completing above tests, shut engine off, drain reservoir. Disconnect and remove gauge hose and valve from pump and pump pressure line. Reconnect pump pressure line to pump, tighten hose-to-pump connector. Fill reservoir to level mark with Ultra-matic Drive Fluid, start engine. Turn wheels from full left to full right position several times to bleed system of air. Add oil as required. Check pump pressure line at pump for fluid leakage. Install reservoir gasket, cover, clamp and clamp screw on reservoir, tighten screw.

REMOVAL & INSTALLATION: Proceed as follows:

▷*CAUTION—Before removing assemblies thoroughly clean the assembly and surrounding parts to prevent dirt from entering assemblies.*

NASH Control Valve Removal From Car: Disconnect oil pressure and return hoses at control valve and two lines connecting valve to power cylinder. Remove cap and gasket from outer end of control valve, then remove self-locking nut and special washer located under cap. Remove two valve-to-linkage attaching bolts, then remove control valve.

Installation: Slide control valve spacer and control valve assembly on bolt of linkage. Be sure spacer sleeve is in place on special bolt. Install special flat washer and a new self-locking nut on end of bolt at outer end of control valve. Adjust nut until there is just a slight amount of play. NOTE—If nut too tight, spool may bind in housing, if too loose, there will be excessive lost motion before spool moves. Reinstall gasket, cap and oil lines.

PACKARD Control Valve Removal From Car: Remove cotter pin and ball stud nut attaching forward end of pitman arm to control valve. Using tool No. PK-11, Ball Stud Remover, install jaw of tool between pitman arm and ball stud in control valve. If dust cap spring is under jaws of tool, pry it up before inserting tool. After ball stud loosened, push up on linkage to release ball stud and control valve from pitman arm. Disconnect reservoir port hole at left end fitting on control valve. Drain fluid. Cap or plug hose fitting to prevent fluid from dripping and dirt getting into hose line. Disconnect pump port hose at connector on valve (second connection from left end). Disconnect left turn hose at connector on valve (connection farthest to right). Using calipers or a rule measure distance between end of control valve and center of connecting rod ball stud (control valve on reinstallation threaded on end of steering connecting rod to exact position from which removed). Unscrew and remove zerk grease fitting from control valve. Loosen bolt in clamp on end of control valve, turn valve to provide room for tools used for disconnecting hose. Disconnect right turn hose at fitting (center front of valve body). Plug or cap hoses to prevent dripping. Unscrew control valve from end of connecting rod.

Installation: Thread control valve onto end of steering connecting rod. Check measurement with a rule or calipers to make sure valve is in identical position from which removed. Tighten locking clamp bolt to 25-30 ft. lbs. Install zerk fitting. Position control valve ball stud in pitman arm, install attaching nut and tighten to 45-50 ft. lbs. Install new cotter pin. Install hoses, tighten.

POWER CYLINDER REMOVAL: Disconnect hoses at power cylinder. Secure hoses in an upright position and cap or plug ends to prevent fluid from dripping and dirt entering hoses. Disconnect power cylinder from frame bracket and piston rod from steering linkage connecting rod, remove power cylinder.

Installation: To install Power Cylinder reverse removal procedures. Tighten attaching nuts to 45-50 ft. lbs. torque.

OIL PUMP REMOVAL: Disconnect oil lines from pump, drain oil into container. Cap or plug fittings of pump. Release pump belt tension, remove pump belt from pulley. Remove pulley, then pump and reservoir.

Installation: To install pump, reverse removal procedures. Tighten pulley to 15-18 ft. lbs. torque.

CONTROL VALVE OVERHAUL: Disassembly—Mark or scribe control valve housing flange to assure proper reassembly. (Packard) Remove capscrews holding control valve cap and gasket to end of control valve spool housing, remove these parts. Remove nut and washer from valve spool bolt. Remove attaching capscrews holding valve spool housing and adaptors to flange end of sleeve and flange assembly, then separate spool housing, adapters, spool washer and spacer from valve spool bolt. Using small punch, push out pin that locks socket tube, stop screw and valve spool bolt together as unit. Unscrew stop screw from socket tube. Remove ball seat spring, ball seats and ball stud from ball socket tube. Remove socket tube from bore of sleeve and flange assembly. (All) Valve spool bushings have "push fit." To remove spool, use round piece of brass rod slightly smaller in diameter than spool stem, tap lightly until bushing free from spool housing bore. This method may be used at either end of spool housing. After removing bushing and spool, bushing at other end may be tapped out.

Inspection & Cleaning: Inspect packings on inner and outer diameters of valve spool bushing for damage or excessive wear. Inspect lands of spool for nicks and burrs. Clean with crocus cloth if necessary. Inspect valve spool housing bore and adaptor bore for wear, cracks, or scoring. Examine valve spool to see if bent. Check condition of ball

CONTINUED ON NEXT PAGE

BENDIX POWER STEERING (Cont.)

seat spring. Replace as required. Wash all parts with carbon tetrachloride or suitable cleaner, blow out passageways with compressed air. Use new packing rings on reassembly.

Reassembly: Install control valve spool in housing. Using seal guide tools install bushings (large bushing on large stem end of spool). Check movement of spool in housing for free operation. (Nash) Slide control valve spacer and control valve assembly onto bolt of linkage. Be sure spacer sleeve is in place on special bolt. Install and tighten attaching bolts. Install special flat washer and new self-locking nut on end of bolt at outer end of control valve. Tighten nut to provide just a **slight** amount of side play. (Packard) Install ball seats in ball socket tube, insert assembly into sleeve and flange assembly. Install ball stud and ball seat spring. Slide stop screw over valve spool bolt, tighten stop screw into ball socket tube which has been assembled into sleeve and flange assembly. Back off stop screw to nearest hole and where stop screw lines up with hole in spool bolt and socket tube. If spool bolt can be rotated, install stop screw pin. Install adapters, spool washer, spool spacer on valve spool bolt. Assemble these parts with capscrews to valve spool housing making certain alignment marks are lined up. Tighten capscrews to 25-30 ft. lbs. Install washer and nut on valve spool bolt and tighten nut so that there is just a **slight** amount of slide play. Center ball stud in socket tube. Check operation of control valve spool in housing by moving stud. Install valve spool body end gasket, cover and capscrews. Torque tighten to 12-15 ft. lbs.

POWER CYLINDER OVERHAUL: Disassembly—Mark or scribe flanges of power cylinder. Remove fluid communication tube from cylinder. Remove adapter assembly from cylinder, then piston rod from bore. Remove scraper washer and seals from adapter and bore.

Inspection & Cleaning: Wash all parts with carbon tetrachloride or suitable cleaner, blow parts dry with air. Inspect cylinder rod end of casting and bore of cylinder body for cracks, dents, wear, broken welds, and excessive scratching. Inspect threads of fittings, examine piston rod to see if bent or threads damaged. Examine ball stud on piston rod for excessive wear and damaged threads. Replace as required. Replace ring packing and seals.

Reassembly: Install seals in adaptor assembly and bore. Install scraper washer. Lubricate piston rod with oil (Hydra-Matic or Ultramatic). With piston rod guide insert piston rod through seals into adaptor housing bore. Install piston assembly in bore (Nash has two rings with end gap .001-.007", sideplay .001-.003". Packard one ring with not more than .016" gap and free movement in groove). Realign scribe marks on flanges, torque tighten attaching bolts to 15-18 ft. lbs. Install oil communcations tube, tighten. Install hoses in fittings of power cylinder, tighten.

PUMP OVERHAUL: *See Eaton Pump data under "Power Steering Hydraulic Pumps" for complete data.*

STEERING GEAR ADJUSTMENT & OVERHAUL: *See "Gemmer Worm & Roller' Steering Gears.*

VICKERS & EATON HYDRAULIC POWER PUMPS

HYDRAULIC PUMP OVERHAUL

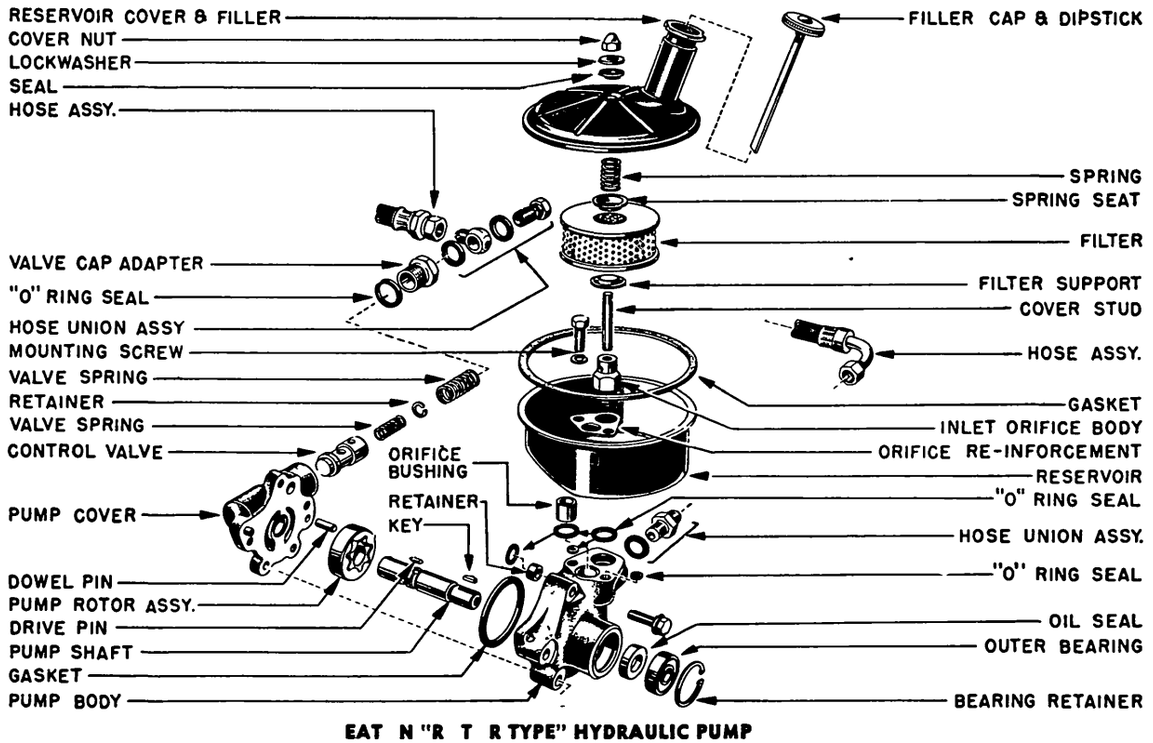
►***OIL PUMP CAUTION—Always cap or plug all pump ports whenever oil lines disconnected and use extreme care to keep dirt out of pump and to keep all pump parts clean.***

EATON OIL PUMP: Disassembly. Thoroughly clean exterior of pump before removing plugs or disassembling parts. Then proceed as follows:

1) Remove reservoir cover and gasket, then drain reservoir. Remove filters, reservoir, then separate pump cover from pump body. *(CAUTION*—Before removing cover place pump with shaft end down to prevent falling out of rollers).

2) Turn pump body over and slowly rotate shaft so that rotors fall free, remove rotors and drive key from shaft. Remove "O" ring seals from pump body.

3) Remove bearing snap ring from recess in body using snap ring pliers, tap lightly on end of shaft, remove shaft and bearing assembly from pump body. Remove inlet fitting and seal from pump body and valve cap adapter seal and orifice plate from cover, then remove flow control valve spring and damper by depressing relief valve slightly and removing snap ring with snap ring pliers.



4) Remove spring, relief valve and flow control valve from cover *(CAUTION*—Place parts where they will not be damaged).

Cleaning & Inspection: *CAUTION*—Do not wash shaft and bearing assembly in cleaning solvent which may wash lubricant out of sealed bearing (wipe bearing and shaft assembly with clean cloth only). Clean all other parts with clean kerosene or solvent, wipe dry with clean lint-free cloths. Inspect bearing in cover and replace if worn or noisy. Inspect shaft for wear and bearing for wear, roughness, or noisy operation (if either part requires replacement, press bearing off and on shaft in an arbor press). Inspect shaft seal in pump body for wear or damage (if seal requires replacement, drive old seal out with a punch, press new seal squarely into place with spring-loaded edge inward). Inspect valves for nicks, scores, or scratches and also inspect valve bores in pump cover (minor nicks may be removed by stoning). Check valve clearance in cover, valves should be free in bores and clearance must not exceed .0025". Inspect valve springs and replace if weak or distorted. Inspect cover and body for wear caused by rotors, replace if surfaces scored or worn. Inspect both rotors as detailed below and replace **both** rotors if either part worn or scored (rotors furnished as matched sets).

Inner & Outer Rotor Clearance—With one tooth of inner rotor fully meshed in outer rotor, measure clearance between rotors at opposite inner rotor tooth using a feeler gauge. Repeat this check for each rotor tooth. Replace rotors if clearance exceeds .006" (Packard), .008" (Others).

Outer Rotor Clearance in Pump Body—Insert outer rotor in pump body, check clearance between

CONTINUED ON NEXT PAGE

EAT N "R T R TYPE" HYDRAULIC PUMP

HYDRAULIC PUMPS (Cont.)

outer diameter and bushing in body with feeler gauge. Replace pump body if clearance exceeds .006" (Kaiser), .008" (Others).

Rotor Side Clearance—Install both rotors in pump body, place straightedge across face of pump, use feeler gauge to measure clearance between rotors and straightedge. Replace pump body if clearance exceeds .0025".

Spring Tension (Relief Valve) 32 lbs. at 1.18".

Spring Tension (Flow Control Valve)—16 lbs. pull plus or minus 1½ lbs. at 1.20".

Reassembly—If removed, install new oil seal in pump body bore with lip toward rotors. If ball bearing removed from pump new bearing should be pressed on with arbor press until it butts against shoulder on pump shaft. Using all NEW seals and gaskets and lubricating all moving parts with Automatic Transmission Fluid Type A, proceed as follows:

1) Install assembly of pump shaft and bearing in pump body bore. Install ball bearing retainer. Position drive pin or key in pump shaft slot.

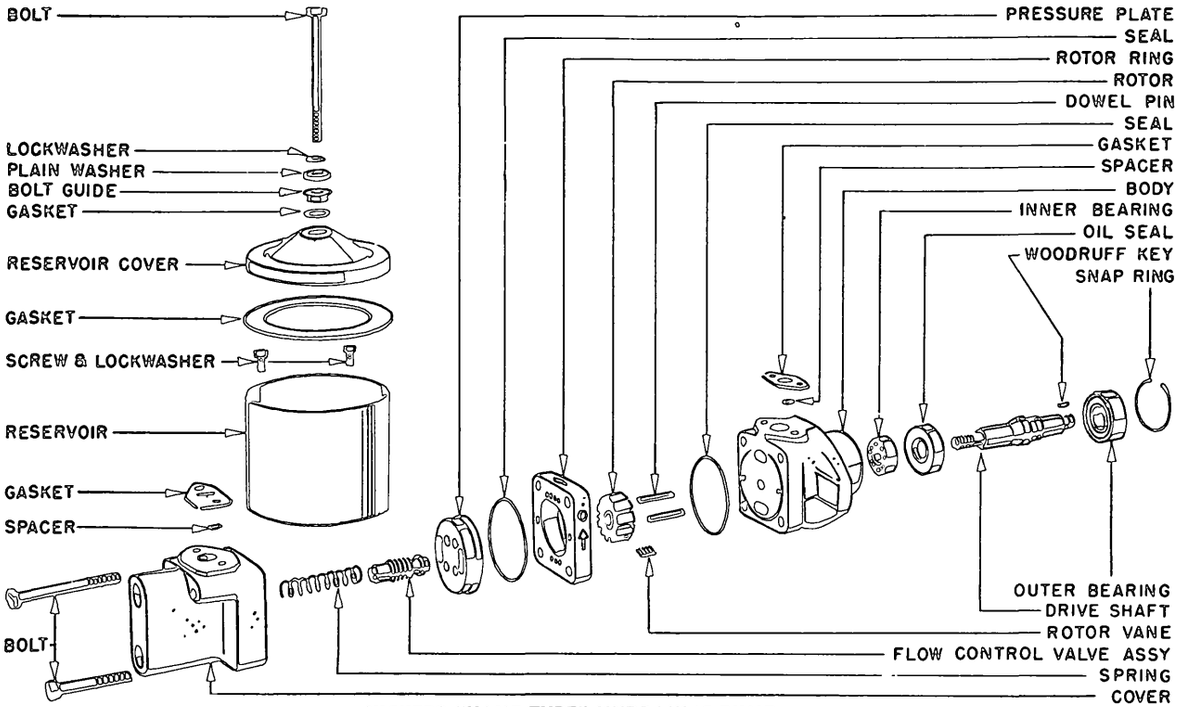
2) Install rotor assembly. If valve subassembly disassembled, install relief valve spring, relief valve, and retaining ring in flow control valve body. Compress assembly into body until there is sufficient room for installing ring in valve body groove, install retaining ring.

3) Install orifice plate in pump body bore. Install flow control valve spring. Install new gasket on hose adaptor valve cap, install and tighten cap. Install new gasket at pump body pressure port and a pump body-to-cover gasket.

4) Install pump cover on pump body. Install screws and torque tighten to 30-35 ft. lbs. (Nash & Packard 25-30 ft. lbs.) Install new "O" ring gaskets on top of pump body, install reservoir and filter.

VICKERS OIL PUMP: Disassembly. Thoroughly clean exterior of pump before removing plugs or disassembling parts. Then proceed as follows:

1) Remove reservoir cover and gasket, then drain reservoir. Remove four reservoir-to-pump mounting screws, then remove reservoir, gaskets, and spacers. Remove pump cover-to-body attaching bolts, then cover assembly with control valve assembly and spring. Discard cover "O" ring seal.



2) Remove pressure and return line unions with "O" rings from pump cover, discard "O" rings. Push spring retainer plug (between pressure and return line unions in cover) inward to remove. Discard "O" ring seal, remove plug snap ring. *NOTE—It is not necessary to remove plug, "O" ring and snap ring to service remainder of pump. Remove only if evidence of leakage at this point.*

3) To disassemble control valve assembly, remove end screws with spacers, relief ball, relief spring guide and relief spring.

4) Lift pressure plate off dowel pins which extend through pump ring, remove pump ring from dowel pins in body. Remove rotor with vanes from body, discard "O" ring from groove in pump body. Remove bearing retainer snap ring from front face of pump body.

5) Remove drive shaft and outer bearing assembly from pump body; press outer bearing off drive shaft over threaded end of shaft, after removing woodruff key from shaft.

6) Using punch, tap drive shaft seal and inner bearing from pump body *(CAUTION*—Seal must be removed first to permit removal of bearing).

VICKERS "VANE TYPE" HYDRAULIC PUMP

▷*HANDLING CAUTION—Use care when handling pump body especially when removing drive shaft and inner bearing with seal to prevent marring or scarring finished surface which mates with cam ring on reassembly of pump.*

Cleaning & Inspection: *CAUTION*—Do not wash large sealed bearing in cleaning solvent which may wash lubricant out of bearing (wipe bearing and shaft assembly with clean cloth only). Clean all other parts with clean kerosene or solvent, wipe dry with clean lint-free cloths. Inspect both bearings for wear or roughness, inspect shaft for wear. Check fit of pump vanes in rotor slots (vanes should be snug but must slide freely in slots), replace rotor if vanes excessively loose, replace vanes if worn or scored. Inspect all ground surfaces of cam ring for roughness or wear (slight irregularities can be stoned out), replace ring if inner cam surface scored or worn. Inspect flat surfaces of pressure plate and body for wear or scoring (faces may be trued up by lapping until smooth and flat) *CAUTION*—all traces of lapping compound must be cleaned out. Inspect relief valve poppet and flow control valve plunger for wear or scoring paying particular attention to seating surfaces. Clean out all passages in pump cover and body.

Reassembly: Use all NEW seals and gaskets. Lubricate all moving parts with clean engine oil and install parts in reverse order of disassembly procedure (above) with particular attention to the following points:

Shaft Seal Installation—After the inner ball bearing is installed in pump body, install seal with the two 1/16" holes in casing toward outside and use a tube or shaft 1 3/4" in diameter to apply pressure on outer edge of seal to seat it in body.

Bearing Installation—Large sealed bearing should be installed with stamped face of inner race toward threaded end of shaft, small bearing with stamped face of inner race toward splined end of shaft. Press on inner race only when installing bearings.

Cam Ring Installation Caution—Install ring with marks made during disassembly lined up and make certain that arrows on ring point in direction of pump rotation (clockwise viewed from front or shaft end of pump).

Rotor & Vane Installation—Install vanes with rounded (radius edge) outward toward cam ring.

Relief Valve Assembly Installation—Make certain that all of the original shim washers are re-installed in the valve plug (these shims control oil pressure). If any of the relief valve parts are replaced, valve operation must be tested and adjusted after pump installed on car as follows:

Relief Valve Testing & Adjustment—Use Gauge J-5176 to check pump pressure. See Testing Hydraulic Oil Pressure (above). Relief valve should start to open (will be indicated by slight buzzing noise in pump) at pressure of 700 lbs. or slightly higher and maximum pump pressure should not exceed 900 lbs. with engine speed increased above idle. If pressure not correct, adjust number of shims in relief valve plug for correct performance (add shims to increase pressure, remove shims to lower pressure).

Final Assembly Test—After assembly completed, rotate pump shaft by hand and make certain pump has free movement. Plug or cap all hose connections to keep dirt out of pump until lines connected.

GEMMER HYDRAGUIDE (CHRYSLER & DE SOTO) (EXTERNAL OIL PASSAGE TYPE)

Chrysler Imperial C53 (1951)—Std.
Chrysler Imperial C54 (1951)—Optl.
Chrysler New Yorker C52 (1951)—Optl.
Chrysler Imperial (1952-Early 1953)—Std. See Note.
Chrysler, Other Models (1952-Early 1953)—Optl. See Note.
DeSoto 6 & 8 (1952-53)—Optl.

►**Late 1953 Note**—*See "Gemmer Hydraguide (Internal Oil Passage Type)" for late 1953 Models.*

►CHANGES, CAUTIONS, CORRECTIONS

►*1951-52 FRONT WHEEL SHIMMY CORRECTION (Power Steering Cars):* If shimmy noted at speed in excess of 25 MPH. when one front wheel hits a chuck hole (especially when right front wheel hits a hole on a curve in the road), correct by replacing steering knuckle upper needle bearing with a **bushing.** *See Chrysler, DeSoto, Dodge, Plymouth Front Suspension data for installation instructions.*

►*REPLACEMENT OF RESERVOIR FILTER (For more efficient operation on early 1951 cars):* Later production type **shorter** filter element should be installed on first cars equipped with original **longer** filter (will correct tendency of pump to lower oil level to such an extent as to pull air into system and cause noisy operation in cold weather). When making this change, ALL OF THE FOLLOWING PARTS should be installed as a unit (includes heavier relief valve spring, top sealing cup with larger flow area, and new lower sealing cup so that filter can be installed either way): No. 1405639 Filter, 1405832 Upper Sealing Cup, 1405833 Lower Sealing Cup, 1405831 Relief Valve Spring, 1405827 Retaining Bolt, 107761 Cotter Pin.

FILTER IDENTIFICATION—Top of new **shorter** filter should be approximately ½" below fluid level in reservoir (original filter extended above fluid).

►*1952 RESERVOIR & OIL RETURN LINE PRODUCTION CHANGE:* **Steel base** reservoir used on later cars (superseding **Aluminum** reservoirs). Same filter cartridge (see above) used for both types and both reservoirs may be interchanged on all Hydraguide pumps. Steel reservoir has oil level mark stamped on inside of case but oil level is same for both types (½" above filter cartridge). New oil return hose and adapter can be used with both reservoirs but **hose and adapter must be used together.**

►*1953 "HIGH SPOT" OR "LUMPY FEELING" AT OR NEAR STRAIGHT AHEAD POSITION (Or feeling of oversteering when turning from center to right or left):* Check and adjust Cross-shaft Backlash and check Steering Tube-and-Column Alignment EXACTLY as detailed below. NOTE—See 1953 Steering Column Jacket Bearing Spring Change (below).

►*1953 ERRATIC STEERING (Normal Operation when cool with gradual loss of steering wheel "feel" with tendency to oversteer as steering unit temperature rises):* To correct this complaint, carefully adjust steering gear and check alignment as listed below.

1) Adjust Cross Shaft (Roller Tooth & Worm Gear Mesh), and Spur Gear (Valve Operating Gear Backlash) in order. See Adjustment. ROAD TEST CAR.

2) Check and adjust VERTICAL alignment of steering gear chuck and steering column. See Steering Gear Alignment. ROAD TEST CAR.

3) Check and adjust HORIZONTAL alignment of steering gear chuck and bracket. See Steering Gear Alignment. ROAD TEST CAR.

►*ROAD TEST CAUTION*—Steering system oil must be at normal operating temperature when road testing car (drive car for sufficient distance to bring oil up to normal operating temperature). OIL TEMPERATURE IS IMPORTANT AND HAS CONSIDERABLE BEARING ON PERFORMANCE.

►*CAUTION*—Hydraguide and steering column alignment is extremely important for correct operation and should be checked whenever mounting bolts found loose (loose bolts will cause misalignment). See Steering Gear Alignment.

►*1953 STEERING COLUMN JACKET BEARING SPRING PRODUCTION CHANGE (To correct slight "lumpy" feeling): New spring, Part No. 1488451 is 2⅞" long and has 8 coils, older spring is shorter and has 5½ coils. See "Lumpy Feeling" Correction above.*

►*1953 STEERING GEAR PUMP-GENERATOR COUPLING FLANGE PRODUCTION CHANGE*—Coupling Flange Part No. 1404025 (Early Type), replaced by Part No. 1552859 (Later Type). CAUTION—Do not interchange these parts except in pairs, or damage to pump and generator can result. Both halves of coupling MUST be of same thickness.

►*1953 HYDRAGUIDE HOUSING-TO-BRACKET LOCKWASHER PRODUCTION CHANGE (To prevent housing loosening and misalignment):* New "Cone Type" lockwasher Part No. 1531726 (9/16"), and Part No. 1531725 (7/16"). When installing new lockwashers, the (concave) indented side should be placed toward the bracket, and all bolts tightened to their proper torque. *CAUTION—Do not use a flat or any type of lockwasher above or below the "Cone Type" washer.*

►*HYDRAGUIDE OIL LEAKAGE CORRECTION:* If leakage of hydraulic oil into steering gear housing noted (10W oil with heavier steering gear grease in housing), or if oil leaks noted at cross-shaft seal, install latest type oil seals as listed below and install seals exactly as specified.

►*REPLACEMENT OIL SEAL CHANGES AND INSTALLATION CAUTIONS:* Install only LATEST type oil seals when overhauling steering gear or to correct oil leaks as follows:

Oil Seal Inspection & Installation—Before using seals, inspect carefully for nicks, cuts, scores, or untrue surfaces at any point and particularly at sealing lip surface and do not use such seals. Inspect the metal-backed Cross Shaft Seals (inner and outer) for a true, flat surface of the sealing face which rests in recess counterbore in housing (must be perfectly flat and approximately 1/16" in width). This face must not be chamfered at inner or outer edges (*NOTE*—On seals which do not have metal back, a very slightly rounded face at the counterbore sealing surface is permissable). All seals must be thoroughly lubricated, internally and externally, with Lubriplate when being installed.

Steering Gear Worm Shaft Seal—No. 1483929 (DO NOT use No. 1316799 or No. 1409491). Identify seal by part number (embossed on seal) and by spring-loaded seal lip. Install with sealing lip **facing valve body.**

Steering Gear Tube Seal—No. 1316788 (all models). Install with sealing lip facing in **toward valv body.** *CAUTION*—Coupling bolt must be tight (gear will be noisy if this bolt loose).

Steering Gear Cross Shaft Seals: Use latest type metal-backed seals as listed below. Leading inner edge of seal is a rubber bead which must be compressed against shoulder in housing to prevent leakage around the outer diameter of the seal. See installation data following.

Cross Shaft Outer Seal—No. 1483930 (DO NOT use No. 1329946 or 1407753). Remove old seal with tool C3137 *(CAUTION*—use care not to damage cross shaft). If bearing being replaced, see Cross Shaft Bearing note below. Clean seal cavity thoroughly with solvent. Wrap exposed end of shaft with cellophane tape to protect seal lip, lubricate seal and slide it over shaft with spring-loaded **lip inward.** Tap seal into place with tool C3136 *(CAUTION*—tap seal only—do not drive on seal). Install snap ring with tapered surface outward (if ring can not be installed without forcing, reduce thickness by rubbing **flat** side on abrasive paper on flat surface). Snap ring should exert slight inward thrust on seal. If snap ring does not exert slight pressure on seal (depth of shoulder too great), install thin washer between seal and snap ring.

Cross Shaft Outer Bearing Note—If new bearing being installed, use tool C3113 to install bearing .005" inward from flat surface of seal recess.

Cross Shaft Inner Seal: *Different types required as follows:*

(1) Steering Gears marked 365/1-1 to 379/5-2 (seal recess ⅜" deep)—No. 1407752 (DO NOT use No. 1316799). Identify seal by part number embossed on outer surface and seal width of 3/16". This seal does not have spring-loaded lip or metal covering. Install with seal lip facing cylinder housing (use tool C3142).

(2) Steering Gears marked 379/5-2 & Up (seal r - cess ½" deep)—No. 1483931. Identify seal by seal width of ⅜", metal covering, and spring-loaded seal lip. Install with seal lip facing cylinder housing (use tool C3142).

►*REPLACEMENT SEAL RING CAUTION*—Use all NEW "O" ring seals whenever steering gear disassembled. Complete set of rings is furnished in Package No. 1450085. Lubricate all rings and seals with Lubriplate when being installed.

►*POWER CYLINDER PISTON RING CAUTION*—Rings furnished in package, No. 1316803, containing 4 phenolic rings and 1 rubber "T" ring (two packages required). **Use only set in which the rubber "T" ring is marked by spot of red dye embedded in the rubber.** *CAUTION*—If rings replaced because of breakage, clean oil pump and reservoir to remove all ring particles (may damage pump). *See Lubrication.*

►*INTERMEDIATE STEERING ARM CAUTION:* Two different types used which must not be interchanged (car will not make complete turn if wrong type installed). Identify arms as follows:

(1) All 6 Cyl. Cars & 8 Cyl. WITH Hydraguide—Arm has straight section immediately adjacent to drag link end.

(2) 8 Cyl. Cars WITHOUT Hydraguide—Arm has extra bend toward bracket at drag link end (other arm does not have this bend).

►*REPLACEMENT STEERING CHUCK (GEAR HOUS-*

C NTINUED N NEXT PA E

HYDRAGUIDE (Cont.) (EXTERNAL OIL PASSAGE)

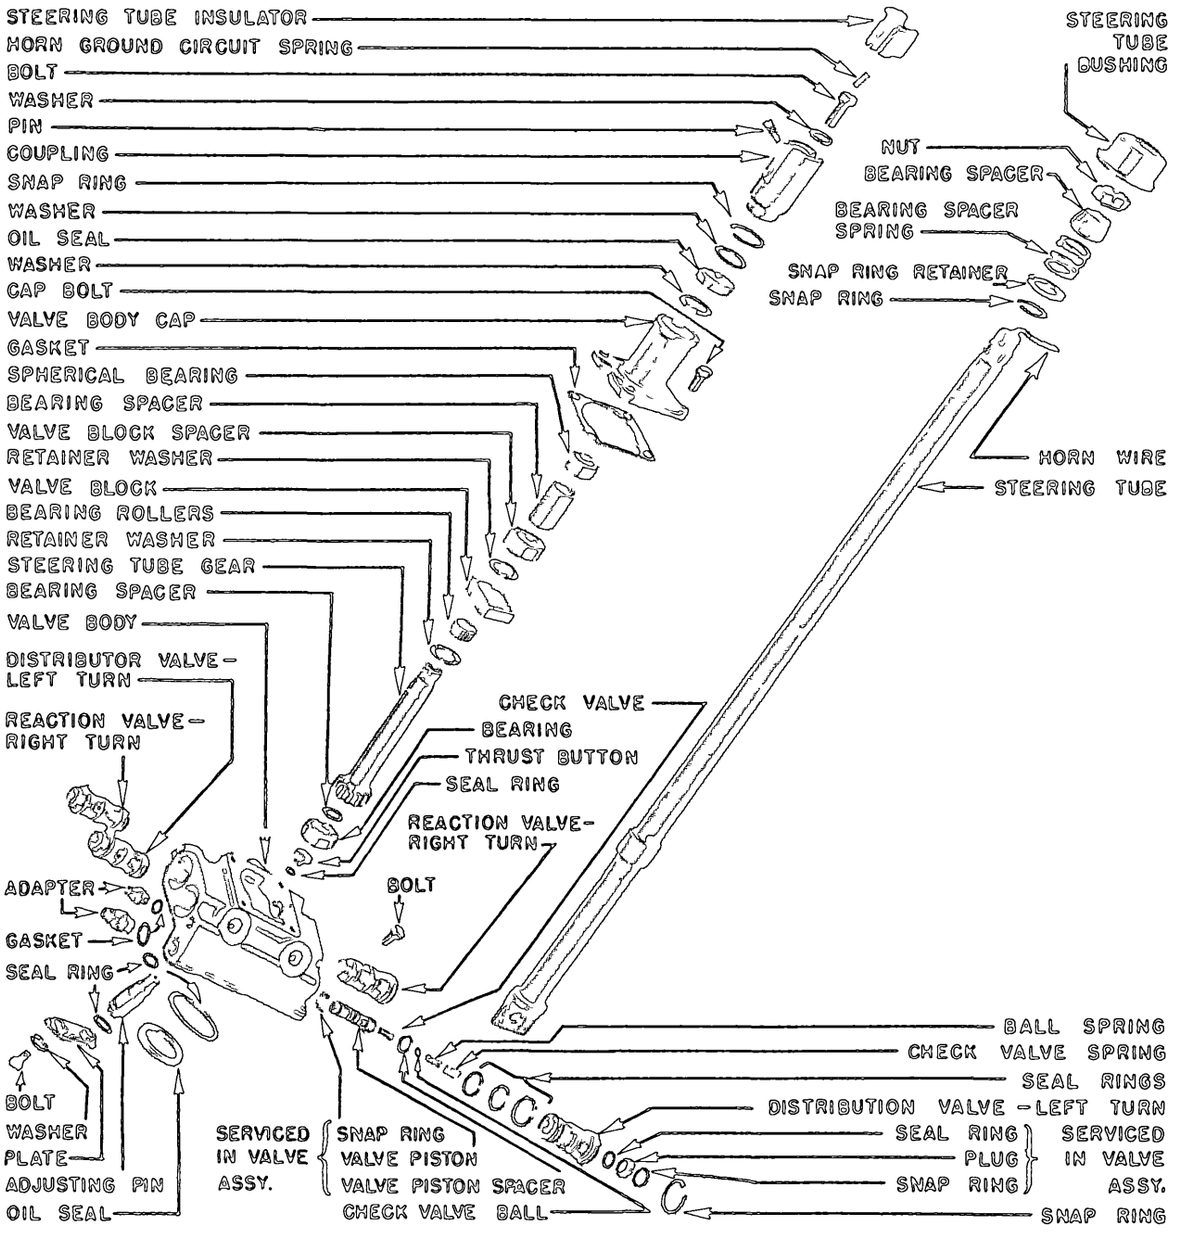
ING) CAUTION: **TWO DIFFERENT types of POWER STEERING CHUCKS (gear housing) and BRACKETS (frame mounting bracket) have been used in production as listed below. Location of chuck-to-bracket holes differs on each type and correct type chuck and bracket must be used together. When replacing either part, identify type by measurements as detailed below and use same type replacement part.**

Power Steering Chuck—Both types same except for location of chuck-to-bracket bolt holes (all internal parts interchangeable for both types).

Identification of Steering Chuck—Place steel scale on flat surface of chuck body directly below filler plug and at right angles to worm shaft center-line (*NOTE*—Some late steering chucks DO NOT have this flat surface and are so identified as being Type "B"). Use second scale placed at right angles to first scale to measure distance up to center of bolt in frame bracket. Measurement will be as follows: Type "A"—⅝". Type "B"—1⅛".

Frame Bracket—Both types have identical bracket-to-frame bolt hole locations so that either type Steering Chuck can be installed provided that correct bracket used with it.

Identification of Frame Bracket—Place 12" scale across center-line of lower and upper chuck mounting bolt holes. Measurement from center-to-center of these two bolt holes will be as follows: Type "A"—6½". Type "B"—7".



DESCRIPTION

DESCRIPTION: Consists of a conventional Worm-and-Roller type steering gear with a hydraulic power system (right and left turn pistons) and a hydraulic control system (right and left turn distributing valves and reaction valves) built in the steering gear housing. Hydraulic pressure for this system is supplied by a combined oil pump and reservoir mounted on the generator commutator end plate and driven by the generator armature shaft. Units are same as used on 1951 Chrysler except for production changes noted above.

ADJUSTMENT

▷*ADJUSTMENT NOTE—Following adjustments may be made without removing steering gear from the car:*

Spur Gear Adjustment (Valve Operating Gear Backlash)—Make adjustment for each 30° turn of the steering wheel. There are twelve teeth on each of spur gears, each corresponding tooth position must be checked for clearance. When adjusting spur gear, care must be taken to see that steering wheel when released will drop in each of positions. Backlash must be adjusted on tightest point of contact. With engine running, pull steering wheel upward and release it. If wheel will not drop in each of 12 positions, spur gear adjustment is too tight. From under hood, loosen adjusting plate lock bolt. Then, with steering wheel held in pulled-up position by tight spot, turn adjusting plate in counter-clockwise direction until wheel will drop. Retighten lock screw and recheck steering wheel in all positions. If adjusting plate is turned as far as it will go from prior adjustment, remove bolt, withdraw adjusting plate and move it to its next serration. Then adjust as outlined above.

HYDRAGUIDE CONTROL VALVE & STEERING SHAFT ASSEMBLY
(VALVE BLOCK SPACER & BEARING SPACER NOT USED IN 1953)

Roller Tooth & Worm Gear Mesh—Due to light loads on worm and roller, an adjustment will be rarely necessary. When required, as when there is a complaint of "lumpy" or "high spot" feeling in steering at or near straight-ahead position, proceed as follows:

1. Disconnect drag link from steering gear arm, remove drain plug, loosen piston arm set screw lock nut and completely remove the (allen) set screw.

2. While one man turns steering wheel to various positions another "feels" (See below) the clearance of roller to worm gear by moving steering arm and making cross shaft adjustment.

CONTINUED ON NEXT PAGE

HYDRAGUIDE (C nt.) (EXTERNAL OIL PASSAGE)

►*"FEEL" CAUTION—To get the "feel" of the actual lash between roller and worm gear it is necessary to first grasp the steering arm and shake it vigorously back and forth, then by using fingers and a light touch (wrist action only) feel clearance or lash. Increased effort to move the arm will result in movement of other parts of the gear and give a false impression of the true lash or clearance.*

3. After making checks at center and turning steering wheel to right and left until proper lash obtained, adjust cross shaft as follows: Remove cross shaft adjustment screw lock cap, move star washer away from gear so that screw may be turned. Loosen adjustment screw until lash felt **with steering wheel in center** position (See "Feel" Caution above). Adjust screw so that lash is just taken out at center. Install and tighten locknut on adjustment screw. Recheck adjustment as tightening of nut may effect final adjustment. Turn steering wheel ⅛ (45°) turn in either direction and check for lash. At ⅛ turn there should be a very slight amount of lash and at ¼ turn some lash should be felt. Install (allen) set screw and tighten securely. Tighten set screw lock nut securely, install drain plug. Connect drag link, fill system with oil and bleed gear by turning steering wheel from one side to other for approximately 10 complete turns.

►*CAUTION—Steering gear hydraulic system must be bled of all air. See Bleeding Instructions below.*

BLEEDING HYDRAULIC SYSTEM: *CAUTION—Before removing reservoir cover, carefully clean cover and adjacent surfaces to prevent possibility of dirt entering the system.*

1. Fill reservoir slightly higher than normal, place cover on reservoir.
2. Start engine and allow to run for short time to circulate oil through hoses and chuck, stop engine and refill reservoir to proper level (see below). NOTE —If gear chuck contained no oil, filling operation may have to be repeated until level remains constant.
3. With engine running at idle speed, turn steering wheel back and forth several times from extreme right to left.
4. Refill reservoir to proper level (see below).
5. Re-install reservoir cover.

LUBRICATION

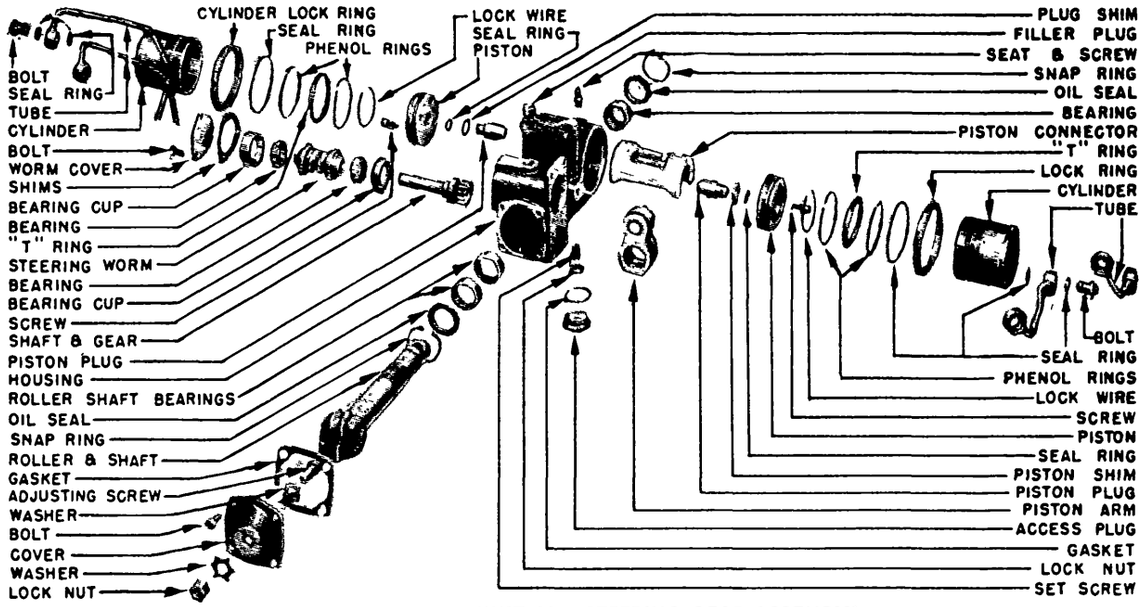
LUBRICATION: Power Steering Hydraulic System. Check oil level every 1000 miles. *CAUTION*—Do not remove reservoir cap or filler plug with engine running and use extreme care to prevent dirt getting into system when reservoir open.

Recommended Oil—SAE 10W Engine oil (use SAE 5W for temperatures under 10°F. or dilute regular oil with approximately 8 oz. of kerosene).

Oil Level in Reservoir—Maintain oil level ½" above top of filter element (oil level mark is stamped on inside of steel reservoirs — aluminum type not marked). *CAUTION*—This level supersedes previous specifications.

Cleaning Oil Pump & Reservoir—*to remove foreign materials which may damage pump (must be done when power cylinder repaired or when broken power cylinder piston rings noted):*

1. Remove both oil lines completely and blow out lines thoroughly with air. *CAUTION*—lines must be re-installed correctly (reversing lines will cause damage to steering gear seals).
2. Remove pump and reservoir assembly from generator but **do not disassemble pump or remove reservoir from pump body.**
3. Remove reservoir cover and filter element, drain reservoir. *CAUTION*—Use care not to allow dirt and foreign material which collects in center of filter element to fall down into pump passages.
4. Remove flow control (divider) valve and pressure relief valves from pump body, remove passage plug from bottom of pump body.
5. Blow out all passages with air *(CAUTION*—use air that is free from moisture and be careful that dirt does not enter pump).



CAUTION—Make certain that four small drill passages in center of reservoir are thoroughly cleaned out (small pieces of phenolic or "T" rings may lodge in these passages). If these passages not clear, oil return from gear chuck will be restricted causing high pressures within the steering gear.

6. Inspect filter element *(NOTE*—foreign material entering filter from hydraulic system will be trapped inside element). Clean or replace filter element.

►*CAUTION—Do not wash or immerse filter element or pump in solvents or other cleaning material which may cause damage.*

7. Inspect flow control valve and pressure relief valve and carefully remove all burrs.
8. Reassemble valves in pump body, install pump and reservoir on generator and connect oil lines *(CAUTION*—Do not interchange lines which would cause damage to steering gear seals), fill reservoir with CLEAN oil, bleed system (see Bleeding data).

Steering Gear Worm & Roller Assembly: Check at 1000 mile intervals. Fill to level of filler plug hole with steering gear grease. *(CAUTION*—do not use pressure gun).

HYDRAGUIDE POWER UNIT AND STEERING GEAR ASSEMBLY

NOTE—SAE 90 Gear Oil used in first steering gears should be replaced with heavier steering gear grease.

TESTING

HYDRAULIC PRESSURE TEST: Use special gauge C-3102 assembly which is designed to be connected to pressure hose connection at pump so that pressure can be checked while unit is operating.

1. Connect gauge C-3102 in the pressure line between pump and hose. Start engine and turn steering wheel. If gauge does not show at least 500 lbs. pressure when steering wheel is in either extreme position, check the pump by turning the shut-off valve to its closed position. If the pressure does not gradually increase as the valve is closed, the flow control valve in the pump may be stuck in an open position or the drive coupling may be broken, *See PUMP below.* If 500 lbs. pressure does show on gauge with engine idling, the pump is in good condition; and trouble is probably in steering gear assembly.

►*TESTING NOTE*—If a gauge is not available, a fairly accurate way of making the test is as follows: Start the engine and turn the wheel to both extreme positions. If the high pressure hose flexes, the pump is in good condition. Look for trouble in the gear assembly. If the high pressure hose does not flex, lack of pump pressure is indicated. See below.

TROUBLE SHOOTING

NO POWER ASSISTANCE (with engine running):

1. **Hydraulic Pressure**—Check hydraulic pressure (see Testing above).
2. **Pump**—Remove reservoir cover and **with plug or finger held over center hol at top of filter start** engine and turn steering wheel. If oil flows through filter, stuck flow control valve plunger is indicated. Shut off engine and free the valve as follows: Disconnect high pressure hose at the pump fitting and insert a ¼" clean blunt probe against valve.

CONTINUED N NEXT PAGE

HYDRAGUIDE (Cont.) (EXTERNAL OIL PASSAGE)

If valve moves inward 3/16" to ¼", then it was stuck open. Remove valve and clean with crocus cloth to remove foreign material or scores; reinstall and test. Pressure should be obtained on extreme turns of 500 lbs. on gauge, or without gauge, the high pressure line should flex. If this does not correct condition, check coupling.

3. Coupling—Remove pump and coupling from generator. Remove snap ring that attaches coupling to pump shaft and remove coupling. If coupling is damaged, turn pump drive shaft at least ten revolutions. If shaft turns freely, install a new coupling on pump. Insert tongue of pump shaft into slot of coupling and fasten with snap ring. Then reinstall pump. If pump shaft binds when turned by hand, replace both pump and coupling. If generator shaft is damaged, repair generator.

4. Drive Belt—Check condition of the fan and generator drive belts and pulleys. Check belt adjustment. See Generator Belt Adjustment on car model page.

5. Steering Gear Assembly—Erratic lack of steering assistance (occasionally or repeatedly) may be due to broken power cylinder piston rings (phenolic rings or rubber "T" rings). Replace piston ring assemblies.

▷*CAUTION—If broken rings found, or if pieces of ring noted when draining system, Oil Pump and Reservoir should be cleaned (see LUBRICATION above).*

POWER ASSISTANCE LACKING IN ONE DIRECTION (Car steers easily in one direction but greater effort required to turn in opposite direction):

1. Steering Gear Misalignment—Check and correct alignment of steering gear and steering column jacket. *See Steering Gear Alignment.*

2. Control Valve Assembly—Check all reaction and distribution valves for correct assembly and installation. Make certain all valves are clean and that bleeder hole in check valve is open.

SENSITIVE STEERING (Too much assistance—front wheels tend to turn too far or too quickly): Can be detected without turning wheels by tendency of engine to slow down, and pressure hose from pump expanding when engine accelerated (hose may also show some seepage). Test as follows:

1. Install gauge and valve (see No Power Assistance Test above). Without turning wheels, accelerate engine and note pressure. If pressure excessive (300-400 lbs.), flow control valve sticking in closed position is indicated. Correct as follows:

2. Remove flow control valve (directly behind large plug to which high pressure hose connected), clean out all foreign material and polish valve with crocus cloth. Re-install valve and check for free movement.

3. Recheck pressure. Gauge should show 30-60 lbs. when engine accelerated.

NOISY OPERATION:

1. Low Oil Level—If steering wheel is turned while engine is not running, oil will be lost through reservoir vent and air will be drawn into system resulting in noisy operation. Replenish oil supply and bleed system. *See BLEEDING HYDRAULIC SYSTEM above.*

2. Singing Relief Valve—Indicates that the steering wheel is being held in either extreme position, or against curb. Release steering wheel.

▷*CAUTION: Do not hold steering gear in either extreme position and accelerate engine at same time. Excessive heat will be generated and may cause damage to pump.*

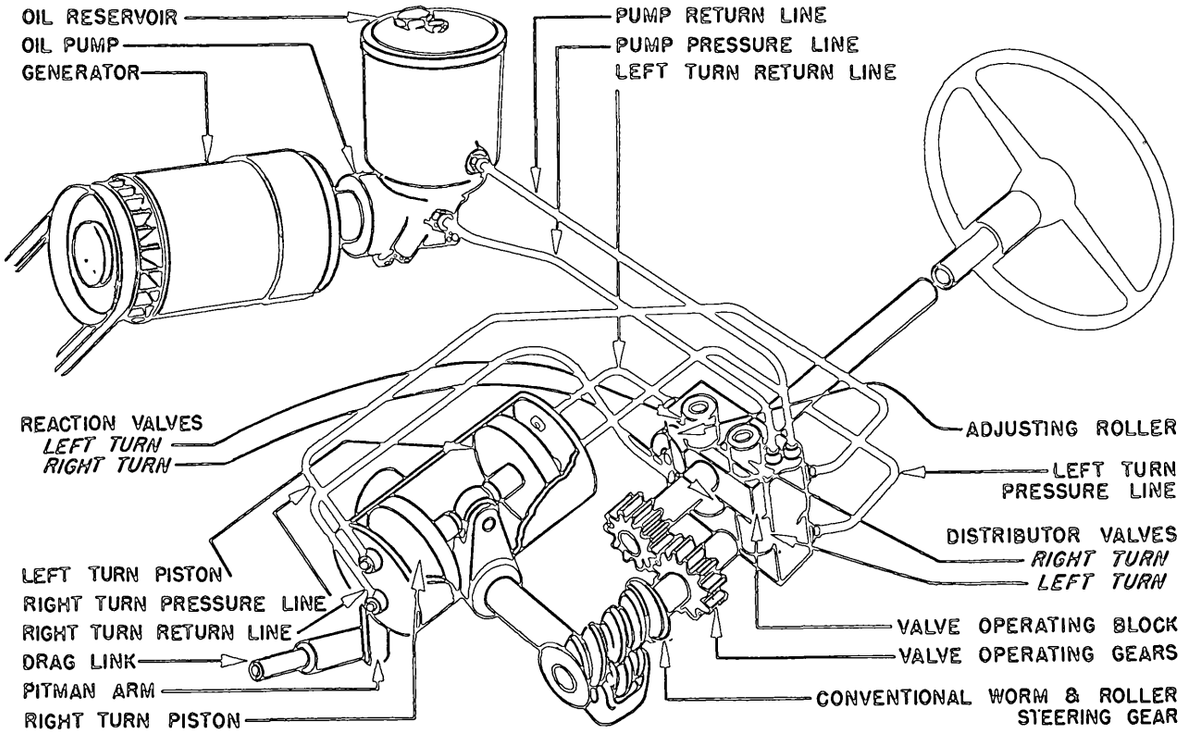
3. Banging or Cracking Noise or Thump when turning corners—Indicates loose clamp bolt on steering arm (tighten to 120 ft.lbs. using a torque wrench), loose mounting bolts, or misalignment between steering column jacket bearing and steering tube. *CAUTION*—when tightening steering gear-to-bracket bolts or bracket-to-frame bolts, alignment must be checked. *See Steering Gear Alignment.*

4. Valve operating gears out of adjustment. *See Spur Gear Adjustment.*

5. Rubber insulator between steering gear and steering column jacket worn or out of place.

LEAKS:

1. Between Reservoir and Pump—Remove lower plug on pump and drain reservoir. Check to see that the four reservoir to pump screws are tight. If they are tight, the leak is probably due to "O" rings not sealing. Remove the four screws and lift reservoir from pump. Replace all six "O" rings in proper position and examine pump and reservoir surfaces for flatness and freedom from surface defects. Tighten screws to 7-12 ft. lbs. torque.



2. At Banjo Fittings—Cross-over lever on gearshift may interfere with fluid lines going to gear assembly and cause leaks at banjo fittings. Loosen banjo fittings. Pry between the lines and gearshift lever rod and force lines and rods apart, allowing fitting to move a little. While holding lines apart, tighten fittings to 16-20 ft. lbs. torque.

3. Between Cylinder Mounting Lock Rings & Housing: Replace "O" ring gaskets as follows: Back off lock ring far enough to permit removal of old "O" ring, disconnect banjo oil line connections on cylinder, slip new "O" ring (use two rings if necessary) under pipe connections and stretch ring over lock ring. Apply lubriplate to "O" ring and tighten lock ring to 35-45 ft.lbs. torque.

EXCESSIVE PLAY IN STEERING WHEEL:

1. Check and adjust valve operating gears (spur gears) and steering gear worm and roller. *See ADJUSTMENT.*

2. Tighten steering gear-to-bracket bolts to 65-75 ft.lbs. torque and bracket-to-frame bolts to 50-56 ft.lbs. torque with a torque wrench. *See Hydraguide Mounting Bolt Loosening Correction.*

HYDRAGUIDE STEERING GEAR HYDRAULIC CIRCUITS

REMOVAL

Chrysler (1951-52), DeSoto (1952-53):

1. Center steering gear in straight ahead position.

2. Remove horn blowing ring ornament by pushing in and turning to left. Remove ornament retainer spring and pad. Remove three attaching screws holding horn blowing ring in place and remove ring. Disconnect wire from terminal on travel plate and insulator assembly. Remove bushing, travel plate, horn blowing contact ring spring and triangular ground ring. Then curl wire into steering gear tube to make room for pilot of steering wheel puller. Remove nut and pull wheel with Tool C-612.

3. Remove clutch, brake and accelerator pads and remove shrouds around hand brake and at bottom

CONTINUED ON NEXT PAGE

HYDRAGUIDE (C nt.) (EXTERNAL OIL PASSAGE)

of steering gear column jacket. Fold carpet back away from pedals and steering column and remove three screws and draft pad from around steering column.
4. Disconnect accelerator rod from bell crank just behind engine at fire wall. Then remove screws from the section of floor board around pedals and steering column, and remove floor board, accelerator pedal and rod as an assembly.
5. Disconnect transmission cross-over rod by removing retainer clip.
6. Disconnect horn wire from steering column jacket connector. Then remove two attaching screws and remove connector from steering column jacket. ***(CAUTION—Remove connector from steering column tube BEFORE jacket assembly is withdrawn from tube.)*** Disconnect the six turn signal wires by pulling three wires out of each connector plug.
7. Slip vacuum hose clamp off of hose and disconnect hose from vacuum line (if brake booster used).
8. Disconnect transmission shift rod from shift lever control arm. Remove the two top capscrews attaching steering gear assembly to frame (leave the bottom screw in place until after drag link is disconnected).
9. Raise front of car and from underneath, disconnect the drag link from the steering arm. Disconnect cable and remove starter. Disconnect the two clips holding vacuum line to frame so line can drop down (cars with brake booster only). Remove bolts attaching master cylinder push rod to brake pedal. Remove brake pedal bushing lock and slide pedal outward on shaft far enough to clear pedal return stop screw. Then move pedal backward toward seat.
10. From under hood, disconnect pressure and return hoses running between gear housing valve body assembly and the pump and reservoir. Disconnect hoses at housing valve body and tie up out of way to avoid dripping oil. Install caps on the two hose fittings on housing valve assembly.
11. Reach through floor board opening from front compartment and loosen the remaining capscrews holding gear assembly to frame. ***Do not remove screw.*** From behind instrument panel, remove the 5/16" nuts from two studs holding steering column jacket upper shroud to instrument panel.
12. Lower steering column jacket and shroud assembly until studs are free. The entire column assembly and gear housing pivots on the remaining housing to frame bracket capscrew. Pull entire column jacket and shroud assembly off steering gear tube. Remove the insulator pin that connects steering tube to tube coupling on housing assembly and remove tube.
13. Remove the remaining housing to frame capscrew and withdraw the steering gear assembly out through the front compartment.

Chrysler (1953):
1. Remove horn blowing ring, turn steering wheel to extreme left position (to allow for removal of drag link), remove steering wheel.
2. Remove steering column jacket toe pad, floor mat, clutch and brake pedal pads. Remove the two steering column to instrument panel screws and clutch and brake pedal floor pan toe board cover.
3. Remove clutch pedal shaft horseshoe lock and slide pedal sideways and toward rear of car to allow clearance for steering gear assembly removal.
4. Remove shift linkage clevis pins from bell crank assembly in engine compartment, disconnect directional signal inidcator wires and pressure and return hoses from steering column assembly.
5. Raise car off floor, remove left front wheel and drag link. Remove side shield, then steering gear attaching bolts.
6. Reinstall front wheel, lower car and remove steering gear assembly through toe board opening.

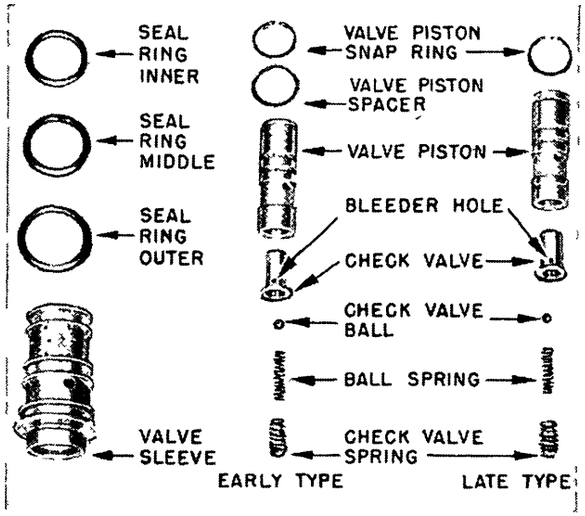
STEERING GEAR OVERHAUL

►***OVERHAUL NOTE*—The Gear Housing, Valve Body, and the Pump and Reservoir Assembly comprise the three major units of Hydraguide. Overhaul of each unit is outlined separately below.**

►***CAUTION—Cleanliness is extremely important in overhauling the steering gear to prevent entrance of dirt into hydraulic system. Thoroughly clean entire assembly before disassembling any parts and use great care to keep dirt out of the hydraulic system.***

VALVE BODY OVERHAUL: Removal from Gear Housing: Remove clamp bolt from steering arm, remove arm from shaft using puller C-143.
1. Remove piston arm access plug from bottom center of cylinder housing, and drain unit by turning so that oil will run out of all hose connections. Remove filler plug in worm gear housing and drain thoroughly.
2. Loosen the power arm adjusting screw locknut and remove adjusting screw with an Allen wrench. Remove bolt from steering gear arm and remove arm from cross-shaft (if not removed previously).
3. Remove tube fitting bolts ***(using a socket and not an open end wrench).*** Remove the long hydraulic tube first, then the short one and then the other two. ***CAUTION—Remove the two "0" rings from each fitting to avoid losing them.***
4. Remove the four capscrews holding valve body worm and roller shaft and cylinder housing, separate valve body housing from cylinder housing.

Disassembly of Valve Body:
1. Remove snap ring from each valve using snap ring pliers Tool C-3106. Withdraw each valve assembly from valve body. Remove worm gear seal and large and small "0" rings.



►***CAUTION—Mark each valve assembly to insure correct reassembly. When valves are disassembled for cleaning and inspection, keep the component parts of each valve together. THESE PARTS NOT INTERCHANGEABLE.***
2. Clean all valves thoroughly in solvent, then remove free floating check valve from each valve sleeve and check the bleeder hole. If hole is plugged make sure it is cleaned out. A plugged hole will cause faulty steering. Blow dry with compressed air reassemble check valve and piston on valve sleeve.

►***REPLACEMENT VALVE CAUTION*—Two types of distribution and Reaction Valves have been used (see illustration). When replacing early type valve VALVES MUST BE REPLACED IN PAIRS (both Distribution or both Reaction valves must be same type).**
3. Remove the four capscrews attaching the valve body cap to the valve body, lift out the steering gear tube gear and cap assembly. Disassemble as follows:

Valve Body Cap Disassembly: Clamp steering tube coupling in a vise. ***CAUTION—Do not clamp the tube gear or valve cap casting in the vise which might damage these parts.***
1. Remove bolt holding coupling to the tube gear.
2. Mount puller Tool C-3112 (adapted to C-293 puller stand) on valve cap and steering tube assembly in order to pull coupling from shaft, then slide tube gear, valve block, valve block spacer and steering tube bearing out of valve body cap.
3. Remove oil seal snap ring, then lift out the outer washer. Drift out the inner washer and oil seal using a drift of suitable size.

NOTE—Check steering gear tube gear oil seal for leakage and inspect tube gear, bearing rollers and valve block for damage or wear.

Valve Body Cap Reassembly: Install inner oil seal washer against shoulder in cap, then install oil seal using Tool C-3143 ***(oil seal lip inward)***, far enough to allow installation of outer washer and snap ring. Install outer washer and insert snap ring. Position steering tube gear assembly in cap, then install coupling on tube gear and secure with bolt and washer. Tighten to 20 ft. lbs. torque.

CONTROL VALVE ASSY. CHANGES

Valve Block Adjusting Pin: Evidence of leakage around the valve block adjusting pin, or a bent adjusting plate, indicates that the steering gear has been turned while the hydraulic line fittings were capped or that the lines to the pump were cross-connected. Remove adjusting pin and install new oil seal as follows:

►***PRODUCTION CHANGE CAUTION—On later models, adjusting pin is retained by snap ring and pin is removed differently (see 1B below).***

1A. On early cars (without adjusting pin snap ring), remove adjusting plate bolt and washer using care not to disengage plate from adjusting pin splines, pull out on plate and rotate it back and forth at same time to withdraw pin from the valve body.

1B. On later cars (with adjusting pin r tained by snap ring), remove adjusting plate bolt and washer, remove plate, remove snap ring retaining adjusting pin, remove pin.
2. Remove spur gear thrust button and seal, spacer, and adjusting pin roller assembly from within the valve body.

CONTINUED N NEXT PAGE

HYDRAGUIDE (Cont.) (EXTERNAL OIL PASSAGE)

3. Inspect needle bearings in adjusting pin roller for wear or damage and replace if required. Use tool C-3141 to drive out old bearing and opposite end of tool to install new bearing in roller.
4. Install a new seal ring on spur gear thrust button, then install thrust button, spacer, and roller assembly within valve body.
5. Install new seal on adjusting pin, insert pin into valve body from outside and make certain that it engages roller assembly and spacer. On later cars, install pin retaining snap ring, install adjusting plate on splines of adjusting pin so that space is provided to allow plate to swing in a clockwise direction for adjustment after steering gear reassembled, install adjusting plate bolt and washer.

Reassembly of Valve Body: Use all NEW "O" ring seals and gaskets, lubricate all seals with Lubriplate
1. Insert steering tube gear and cap assembly in valve body using a new gasket, tighten four cap bolts to 16-20 ft. lbs. torque.
2. Install the four valve assemblies in valve body *(CAUTION—each assembly must be returned to same cylinder from which removed)*. Secure valve assembly with snap ring installed with beveled edge out.
3. Install large and small seal rings in valve body.
NOTE—Worm gear seal should be installed during valve body installation on gear housing (see below).
4. Remove valve block adjusting plate bolt and turn adjusting plate counter-clockwise (necessary to permit installation of valve body on housing.
AFTER worm gear and cylinder body reassembled, install valve body on gear housing. See "Valve Body Installation on Gear Housing" (below).

WORM GEAR & CYLINDER BODY: *CAUTION*—Before disassembly, scribe index marks on both cylinders and body to insure reassembly in same positions (mark one cylinder with single line, and other cylinder with double line to prevent interchanging cylinders). DO NOT punchmark cylinders.

Disassembly of Power Cylinders & Pistons:
1. Loosen both cylinder lock rings with spanner Tool C-3107, back rings off several turns. Then install two special studs, Tool C-3108, into tube fitting holes of cylinder and insert pry bar between studs and loosen cylinder in housing (DO NOT REMOVE CYLINDER). Loosen other cylinder in like manner.
2. After loosening cylinders, unscrew and remove BOTH CYLINDERS AT THE SAME TIME. *(CAUTION—If both cylinders are not removed at the same time, damage to piston rings may result).*
3. Pry the lockwire from the end of one piston with a screw driver. Remove Allen head screws from piston, then slide piston away from connector, and remove from cylinder.
4. Swing piston arm and roller against plug of remaining piston by turning the worm gear. Piston and connector assembly can then be removed from cylinder body.
5. Examine the cylinder bores and pistons for score marks. (Very light scoring or scratches can be removed with crocus cloth). Replace any part that shows excessive wear or damage. Check phenol rings and rubber "T" rings and replace if necessary.

▷*PISTON RING REPLACEMENT CAUTION*—Use only piston ring sets (No. 1316803, containing 4 phenolic rings and 1 rubber "T" ring) in which rubber "T" ring is marked by spot of red dye imbedded in the rubber. *See Power Cylinder Piston Ring Caution in CHANGES & CORRECTIONS (above).*

Disassembly of Steering Gear Shaft & Worm Shaft:
1. Remove snap ring retaining steering gear shaft outer oil seal and remove seal using Tool C-3137.
2. Remove steering gear shaft adjusting screw locknut and star washer. Turn shaft to center position. Next, remove the four shaft cover bolts and push out shaft to allow removal of cover. Turn adjusting screw in and then slide screw and cover out of slot in end of shaft.
3. Withdraw steering gear shaft from piston arm and housing, remove piston arm from housing.
4. Remove the three worm cover bolts and lift off cover and shims. *(Retain shims together for reassembly).* Remove worm gear lower bearing cup, bearing and worm from housing.
5. Check roller tooth on steering gear shaft for free movement. If there is side play or sticking bearings, install a new shaft and roller assembly.

Steering Gear Shaft Roller Bearing Replacement: Inspect the three roller bearings that support steering gear shaft. If they are damaged or have no end play, or not free, install new bearings:
1. Remove steering gear shaft inner oil seal snapring, and pry out inner oil seal with a screw driver.
2. Remove steering gear shaft inner and center bearings using Tool C-3114, remove outer bearing using Tool C-3113.
3. Install new center bearing using Tool C-3114 (place tool against lettered side of bearing), then install new inner bearing using the same tool.
4. Install inner bearing oil seal (see Caution below) using Tool C-3142 with *lip of seal toward inside.* Use tool C-760 to install inner bearing oil seal snap ring. Make certain that ring is seated in groove and that *beveled edge of ring is outward.*

▷*REPLACEMENT OIL SEAL CAUTION—Use only LATEST type oil seals. See Replacement Oil Seal Caution in CHANGES & CORRECTIONS (above).*
5. Install outer bearing using Tool C-3113.
NOTE—Outer bearing oil seal is installed as part of reassembly procedure AFTER steering gear shaft installed in housing.

Reassembly & Adjustment of Worm & Roller Shaft: Install the worm assembly in the housing, install lower cover with all original shims, tighten cover bolts securely. Turn worm gear throughout entire range and check for binding or excessive free play. Worm should turn with slight drag but no binding. If worm binds, ADD shims under cover; if worm is too free, REMOVE shims from under cover. When correct adjustment secured, use sealer on cover bolts and tighten evenly to 17 ft. lbs. torque.
ADJUSTING SHIM NOTE—Adjusting shims color-marked for identification and furnished in following thickness: .003"—White, .006"—Red, .011"—Gray.

Adjustment of Power Piston Clearance: BEFORE installing power cylinder parts, complete the power piston assembly out of the housing by mounting both pistons and plugs on piston connector and placing the piston arm roller in position between the piston plugs. Then check clearance between piston arm roller and piston plugs with a feeler gauge. This clearance should be as close to ZERO as possible. Adjust by varying thickness of shims between each piston and its plug. After this adjustment completed, remove one piston from connector (for installation) but keep piston and adjusting shims together to insure correct assembly.
ADJUSTING SHIM NOTE—Adjusting shims furnished in following sizes: .107", .109", .111", .113", .115", .117", .119".

Steering Cross Shaft Installation:
1. Install the steering shaft and piston arm in the housing so that shaft splines mesh with piston arm splines. Install steering gear shaft cover and adjusting screw to slot in end of shaft. Turn adjusting screw counter-clockwise to draw shaft cover up to the housing. Coat cover bolts with suitable sealer and install. Tighten bolts securely.
2. Install steering gear shaft outer oil seal with lip to the inside. Use Tool C-3136. Install outer snap ring with beveled side out, and eyes in ring toward bottom of unit. Snap ring in this position will aid in removing ring when steering gear assembly is installed in car.

▷*REPLACEMENT OIL SEAL CAUTION—Use only LATEST type oil seals and observe cautions listed in Replacement Oil Seal Caution in CHANGES & CORRECTIONS (above).*
3. Install pitman arm on roller shaft and tighten clamp bolt to 100-120 ft. lbs. torque.
4. Set the worm gear at center position (mark on worm gear must be at top of gear) and pointing toward top center of gear housing. Then with one hand on pitman arm, turn worm gear to check backlash between worm and roller. Turn shaft adjusting screw so that there will be no backlash felt while the worm gear is turned between approximately 90° either side of center line. Now install the star washer and locknut on shaft adjusting screw.

▷*CAUTION—DO NOT tighten piston arm-to-steering cross shaft Allen set screw until AFTER Power Cylinders installed and adjusted.*

Power Cylinder Installation & Adjustment:

▷*CAUTION—Procedure below supersedes previous recomendations and will prevent piston ring breakage when adjusting cylinders for correct piston travel.*
1. With piston arm roller turned to either extreme position, install piston and piston connector assembly to the housing with the piston plug bearing against piston arm roller. Then, by turning the worm gear, piston arm will swing back to center as the piston assembly is pushed in. Assemble the other piston and plug assembly to opposite side of piston connector and reinstall Allen head screws *(CAUTION*—make certain that adjusting shims installed between piston and plug), tighten Allen head screws in both piston heads to correct torque, install piston lock wires.
2. Center the piston assembly so that pistons extend an equal amount on both sides of the housing. Lubricate cylinder bores with engine oil, lubricate piston "T" rings and phenolic rings with Lubriplate or engine oil.
3. Install both cylinders over the pistons using extreme care not to crack or distort piston rings as they enter the cylinder bores (CAUTION—install cylinder on same end of housing from which they were removed). AFTER both cylinders started on the pistons, thread BOTH cylinders into housing simultaneously until both cylinders bottom in housing.
4. Turn the worm shaft gear to the left and at the

CONTINUED ON NEXT PAGE

HYDRAGUIDE (Cont.) (EXTERNAL OIL PASSAGE)

same time unscrew the upper cylinder *(CAUTION—*keep piston head against or very close to top of cylinder during this opeartion), continue to turn worm shaft to a total of EXACTLY 1⅝ turns from the beginning center position *(CAUTION—*DO NOT exceed 1⅝ turns with piston bottomed in the cylinder. If scribe marks made before disassembly do not line up at this point, turn the cylinder IN *(CAUTION—*NEVER turn cylinder farther out) to align hydraulic tube fitting holes in cylinder and disregard scribe marks (may require turning cylinder in as much as ½ turn from scribe marks). After cylinder adjusted, return worm shaft to center position.

5. Adjust opposite (right turn) cylinder by repeating step 4 (above) and turning the worm shaft to the right exactly 1⅝ turns.

6. After both cylinders correctly adjusted, recheck rotation of worm shaft gear. Shaft rotation MUST NOT EXCEED 1⅝ turns to left or right from center position to the point where piston contacts cylinder head.

7. Install special studs, Tool C-3108, in tube fitting holes in cylinder, place a bar between the studs to hold the cylinder from turning, tighten cylinder lock ring to 35-45 ft. lbs. torque. Tighten both cylinders in this manner.

8. After both cylinders installed and adjusted, turn worm shaft to center position, install Allen set screw in piston arm and tighten screw to 30-35 ft. lbs. torque (weld 2" length of ¼" Allen wrench in a socket to enable use of torque wrench in tightening this screw). Tighten locknut to 16-20 ft. lbs. torque. Install access plug in housing using a new gasket. ***CAUTION—A loose piston arm set screw will result in a lumpy or catching feel in the steering gear.***

Valve Body Installation on Gear Housing:

1. Install worm shaft gear seal as follows: lubricate seal thoroughly with Lubriplate (internally and externally). Slide seal over worm shaft gear carefully to avoid damaging seal lip on gear teeth with **sealing lip facing valve body,** make certain that seal fits in slight recess in gear body and that lip bears on journal of worm shaft gear.

2. Coat valve body-to-gear chuck "O" ring with Lubriplate and install this ring.

3. Turn worm gear to center position (mark on worm gear must be at top and pointing toward top center of gear housing), turn spur shaft gear so that slot in steering tube connector is parallel to valve assemblies, mesh gears and install valve body on gear housing. Install two capscrews at opposite corners of valve body and tighten these screws evenly to gently draw valve body into position against gear housing *(CAUTION—*see that seal enters recess in valve body and use extreme care not to damage seal as the two bodies are drawn together). AFTER valve body seated firmly on gear housing, install remaining two capscrews, tighten all screws evenly (tighten opposing screws together) to correct torque of 16-20 ft. lbs.

CAUTION—If valve body not installed exactly as detailed above, valve housing may be distorted or seal cocked in its recess.

4. Eliminate backlash between the worm spur gear and the tube spur gear by making a preliminary adjustment of the valve block adjusting plate as follows: turn adjusting plate clockwise until all backlash is taken up at the coupling. Install adjusting plate bolt and tighten securely. *NOTE—*Further adjustment may be required after steering gear has been installed in the car. *See ADJUSTMENT.*

5. Coat new seal rings with Lubriplate, insert rings in hydraulic tube fitting, install tubes in reverse order of disassembly (install second longest tube from lower reaction valve to right cylinder first, then install shortest tube from upper reaction valve to left cylinder, finally install remaining tubes). Tighten tube fitting bolts to 16-20 ft. lbs. torque. ***STEERING GEAR ASSEMBLY IS NOW READY FOR INSTALLATION IN CAR.***

INSTALLATION

►**1953 Valve Block and Bearing Spacer Note**—Valve block spacer and bearing spacer used on 1951 & 1952 Models is not used on 1953 Models with redesigned valve body cap.

►**1953 Change—Bleeder Hole** has been eliminated from top center of power cylinder.

*CAUTION—*It is very important to remove shipping caps from fittings on any gear assembly received for replacement, before turning the coupling. Seals at cross-shaft will be upset if caps are not removed.

1. Install steering gear arm to steering gear assembly with curve of arm toward the assembly. (If not already installed). Tighten to 100-120 ft. lbs. torque.

2. Remove caps from pressure and return hose connections on the assembly and turn steering gear tube coupling to extreme right or left position. Then turn coupling back approximately 1¾ turns to center position, and then place punch mark on solid part of coupling to indicate center position.

3. Install steering gear assembly through floor board opening. Using a screw driver, hold lower bolt hole of assembly in alignment with hole in frame bracket and install cap screw. NOTE—Tighten bolt sufficiently to hold assembly rigid for installation of steering tube and jacket, however, leave screw just loose enough so that gear assembly can be pivoted up and down after steering tube and jacket are installed.

►***CAUTION—Before installing steering gear tube, make sure that the small coil spring is positioned in the rubber insulator at the end of tube. Also make certain that the steering tube snap ring retainer is cupped over the snap ring and not over the column jacket bearing spring.***

4. Check to see that snap ring, ring retainer, column jacket bearing spring and bearing spacer are installed in that order on upper end of steering tube. (Refer to illustration).

5. Install rubber chuck-to-jacket insulator over upper casting of chuck.

6. Install steering gear tube by indexing the insulated tongue into the slot of the tube connector in such a way that the punch marks on coupling and the master serration for steering wheel on upper end of tube are in alignment. Then connect tube to coupling by installing the tube insulator pin and peen both ends of pin.

NOTE—Proceed as follows for steering column alignment.

Chrysler (1951-52) & DeSoto 6 (1953)

7. Install steering column jacket assembly by sliding downward over steering tube. Install a ¼" thick spacer Tool C-3109 between the flanged end of jacket and the rubber insulator on steering gear chuck. As the jacket is pushed down against the spacer, the collar at upper end of chuck will engage the spun-in collar on inside of jacket to form a rigid connection between the jacket and chuck. The purpose of the spacer is to align the jacket with gear housing so that the entire assembly can be lined with center of instrument panel opening.

8. Pivot steering gear and column jacket assembly upward so that studs on jacket shroud will enter holes in instrument panel, and place rubber insulater between jacket shroud and instrument panel.

9. From under hood, install the other two cap screws that attach upper side of gear assembly to frame bracket. Then tighten all three cap screws to 75 ft. lbs. torque.

10. Carefully check to see if center line of jacket and shroud assembly line up with center line of opening in instrument panel. If it does not line up, loosen the two upper bracket-to-frame screws from under hood and move entire gear and jacket assembly either to right or left as necessary. Retighten screws to 50-65 ft. lbs. torque. Remove alignment spacer installed in step 7 and push jacket downward against chuck insulator. Then proceed with Item 11 under "All Models" below.

Chrysler (1953) & DeSoto 8 (1952-53)

7. Install steering column jacket and shift tube assembly over steering tube.

8. Install both halves of column shroud on column jacket.

9. Push down on column assembly until the column jacket bottoms on rubber grommet on face of the rear chuck valve body.

►*NOTE—*Steering column assembly contains a spring which forces upward on column jacket. When assembling column jacket assembly to valve body grommet, pressure must be applied to column assembly to push column jacket downward to allow grommet and column to go all the way down on valve body.

10. Tighten shroud to instrument panel screws while holding jacket down.

►*ALIGNMENT NOTE—*Spacing at bottom of column where it enters grommet on valve body will indicate in which direction the steering gear chuck should be moved (horizontally or vertically) to bring column into alignment with gear chuck assembly. The column jacket flange and grommet at base of column should be equally spaced all the way around entire circumference of valve body. See "Horizontal & Vertical Alignment" below.

All Models

11. Adjust the insulated wedge that slides between the jacket shroud and the lower instrument panel so that jacket shroud will fit tightly against both the lower instrument panel and the instrument cluster panel when the stud nuts are installed. *(NOTE—*This wedge is not used on C-53 models).

12. Install stud nuts from behind lower instrument panel. Install horn contact to jacket with two screws, connect horn wire to connector terminal and connect the six wires to turn signal connector. Connect transmission cross-over rod with retainer clip.

13. Connect vacuum line and fasten it to frame with two clips (cars with booster brakes only). Slide brake pedal back into position and secure with new bushing lock.

14. Connect master cylinder push rod to brake

CONTINUED ON NEXT PAGE

HYDRAGUIDE (Cont.) (EXTERNAL OIL PASSAGE)

pedal by installing bolt through push rod end and brake pedal extension. Secure with nut, washer and cotter pin.

15. From under the hood, remove the plugs from pressure and return fittings on gear housing valve body assembly and connect the hoses from pump and reservoir to fittings on assembly. Both hoses have connections of equal size at their pump and reservoir ends. Hook them up so that the line with the small fittings at its gear assembly end is connected to the pump, and the line with the large fitting at its gear end is connected to the reservoir.

16. Connect drag link to steering gear arm and lower car to floor.

17. Remove reservoir cover and add SAE 10-W to level of gasket and reinstall cover. Slip steering wheel on steering tube, start engine and while it is running turn wheel to both extremes. Shut engine off, remove cap from reservoir and fill to 1½" below gasket with oil. *CAUTION—Be sure engine is not running when reservoir cap is removed. Oil will spill into engine compartment.*

18. Replace reservoir cap and start engine. Run until oil becomes warm (5-10 minutes). Turn steering wheel to both extreme positions, hold momentarily and check for leaks. Open bleeder screw at top center of power cylinder until oil flows, tighten screw and shut off engine.

▷*CAUTION—Do not hold steering wheel in extreme travel for more than one minute. Engine should be idling during this operation.*

19. Connect transmission shift rod to shift lever control arm with washer, lock washer and nut.

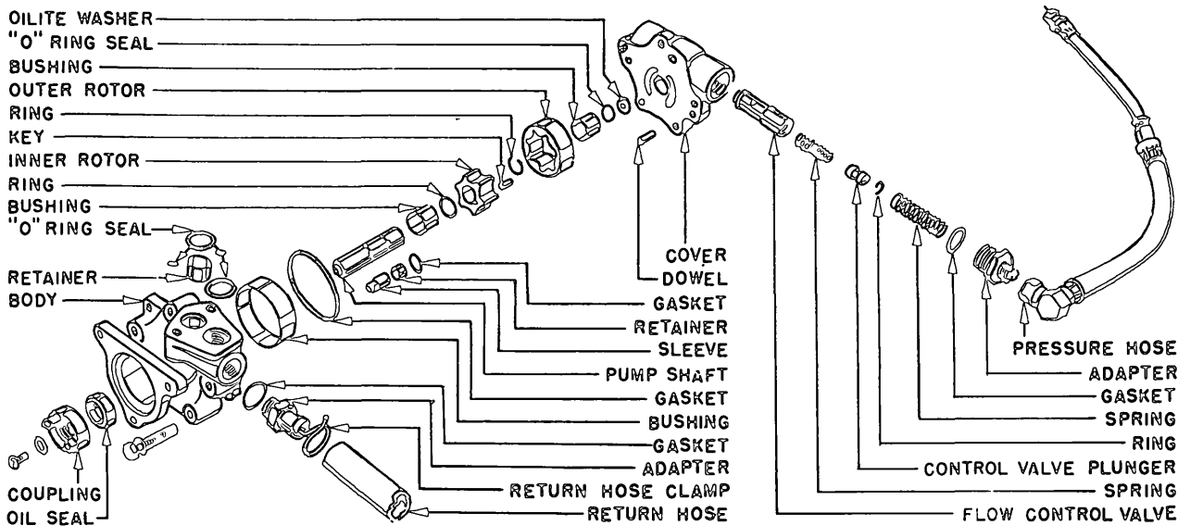
20. Reconnect vacuum hose to line and secure with clamp (cars with booster brake).

21. Reinstall floor board and accelerator rod as an assembly, holding rod up against floor board as it is put in place so that rod goes beneath the offset crook in gearshift control rods. Then from under the hood, connect the opposite end of rod to bell crank behind engine at firewall. Secure floor board in place with screws. Fold mat back in place and install the clutch, brake and accelerator pads.

22. Install shrouds at bottom of steering column jacket and around hand brake.

23. With steering wheel on bench, install component parts of horn blowing mechanism into steering wheel hub in the following order:

(a) Triangular ground ring. Position ring so that screw holes line up with holes in steering wheel hub and with red dot on ring toward top of hub.



(b) Contact ring spring. Install with concave side down.

(c) Travel plate. Install so that screw holes are in proper alignment with holes in wheel hub.

(d) Install horn ring so that three screw holes also line up with holes in wheel hub. Then install three screws with fibre and rubber insulators.

24. With wheels in straight ahead position, slide steering wheel assembly into place on steering tube making sure that master groove on wheel indexes with master serration on tube.

25. Install steering wheel nut and tighten to 35-40 ft. lbs. Pull horn wire from steering tube, install bushing and connect wire to terminal on travel plate. Lay the ornament retaining spring in place, concave side down. Position ornament with three legs indexing with three slots in horn ring, push down and turn clockwise.

HYDRAGUIDE HYDRAULIC PUMP (SINGLE ROTOR TYPE)

STEERING COLUMN HORIZONTAL & VERTICAL ALIGNMENT: If spacing between column and chuck is not equal, loosen bracket-to-frame bolts and shift chuck and bracket in required direction to equalize the spacing between column jacket base, grommet, and valve body face. *CAUTION*—In some instances it may be necessary to install shims between bracket and frame to obtain sufficient movement of gear for proper alignment. Shims should be "U" shaped or flat washers and placed around bracket-to-frame bolts. *DO NOT PLACE SHIMS BETWEEN GEAR AND BRACKET.*

HYDRAULIC PUMP OVERHAUL

▷*1953 HYDRAULIC PUMP-GENERATOR COUPLING FLANGE PRODUCTION CHANGE*—Coupling flange, Part No. 1404025 (Early Type), replaced by Part No. 1552859 (Later Type). *CAUTION*—Do not interchange these parts except in pairs or damage to pump and generator can result. Both halves of coupling must be of same thickness.

▷*PUMP COUPLING NOTE*—Two different types of pump drive coupling have been used and special Pump and Generator must be used with each type coupling (special shaft used with each coupling).

1) Rubber Insulated Coupling—Oilite coupling flanges are pressed on generator and pump shafts and retained by special "thread locking" type capscrew and plain washer (lockwashers should not be used with these screws). A rubber insulator and insulator sleeve are installed between the coupling flanges to transmit the drive.

2) Metal Tongue Coupling—Tongue-and-slot type metal coupling. Coupling members are retained on shaft ends by a retaining ring and slide off after ring removed.

▷*HYDRAULIC PUMP NOTE—"Double Rotor" type pump used 1951-52. "Single Rotor" type used 1953. Removal & Installation procedures are same for both type pumps. Overhaul procedure is different as indicated below.*

HYDRAULIC PUMP REMOVAL: Disconnect the two hoses from pump reservoir assembly and catch oil from pump in a drain pan. Tie the loose ends of hoses out of the way above steering gear assembly to prevent loss of oil. Cover the ends of both hoses. Remove the three pump-to-generator screws and remove pump (*CAUTION*—do not lose coupling insulator and sleeve on pumps with rubber coupling).

Removal of Reservoir From Pump:

1. Remove cover assembly from reservoir, lift out filter element and drain oil from reservoir.
2. Install the small tapered plug Tool C-3117 and the large tapered plug Tool C-3118, into the two holes that permit passage of oil to pump (this will prevent dirt entering pump).
3. Remove the four reservoir-to-pump attaching screws and lift reservoir from pump, being sure not to lose one large rubber "O" ring and five small rubber "O" rings which are used as gaskets between pump and reservoir.

OVERHAUL OF PUMP: *CAUTION*—Cleanliness is extremely important when working on hydraulic pump. Pump should be thoroughly cleaned before disassembling, work bench should be covered with clean paper, and all parts should be kept in clean kerosene until reassembled to protect them from dirt and corrosion.

Disassembly ("Double Rotor" type): Remove drive coupling from shaft and remove drain tube from mounting flange. Then proceed as follows:

1. Remove five through-bolts and lockwashers holding pump assembly together, remove pump rear cover. Remove and discard "O" ring seal from spacer cavity.
2. Remove rear bearing snap ring from shaft. Tap side of rear spacer with a soft hammer to loosen it from locating dowels in pump body, then slide spacer and bearing off pump shaft. Remove "O"

CONTINUED ON NEXT PAGE

HYDRAGUIDE (Cont.) (EXTERNAL OIL PASSAGE)

ring seal from pump body and discard this seal.

3. Hold pump body upright with rear rotors downward and shake body to disengage rotors *(CAUTION*—hold hand under pump to catch rotors). If inner rotor remains on shaft, hook fingers under edges of rotor to pull rotor off shaft and lift out drive key as soon as it is exposed. If outer rotor remains in body, use wire hooks to lift rotor out. LIFT ROTOR OUT EVENLY TO AVOID BINDING WHICH MIGHT DAMAGE BABBITT RING.

►***CAUTION—DO NOT pry rotors out which might cause damage to rotors or babbitt ring. These individual parts NOT furnished for service. Keep each rotor set separate and re-install in same position in pump.***

4. Lift pump body off shaft and away from mounting flange, disengage dowels in flange from the body *(CAUTION*—Front rotors may remain in body and must not be allowed to drop out which may cause them to be damaged). If outer rotor remains in body, lift rotor out with wire hooks. LIFT ROTOR OUT EVENLY TO AVOID BINDING WHICH MIGHT DAMAGE BABBITT RING. If inner rotor remains on shaft, tap shaft and rotor out of bearing in mounting flange, then remove rotor from shaft and lift out drive key.

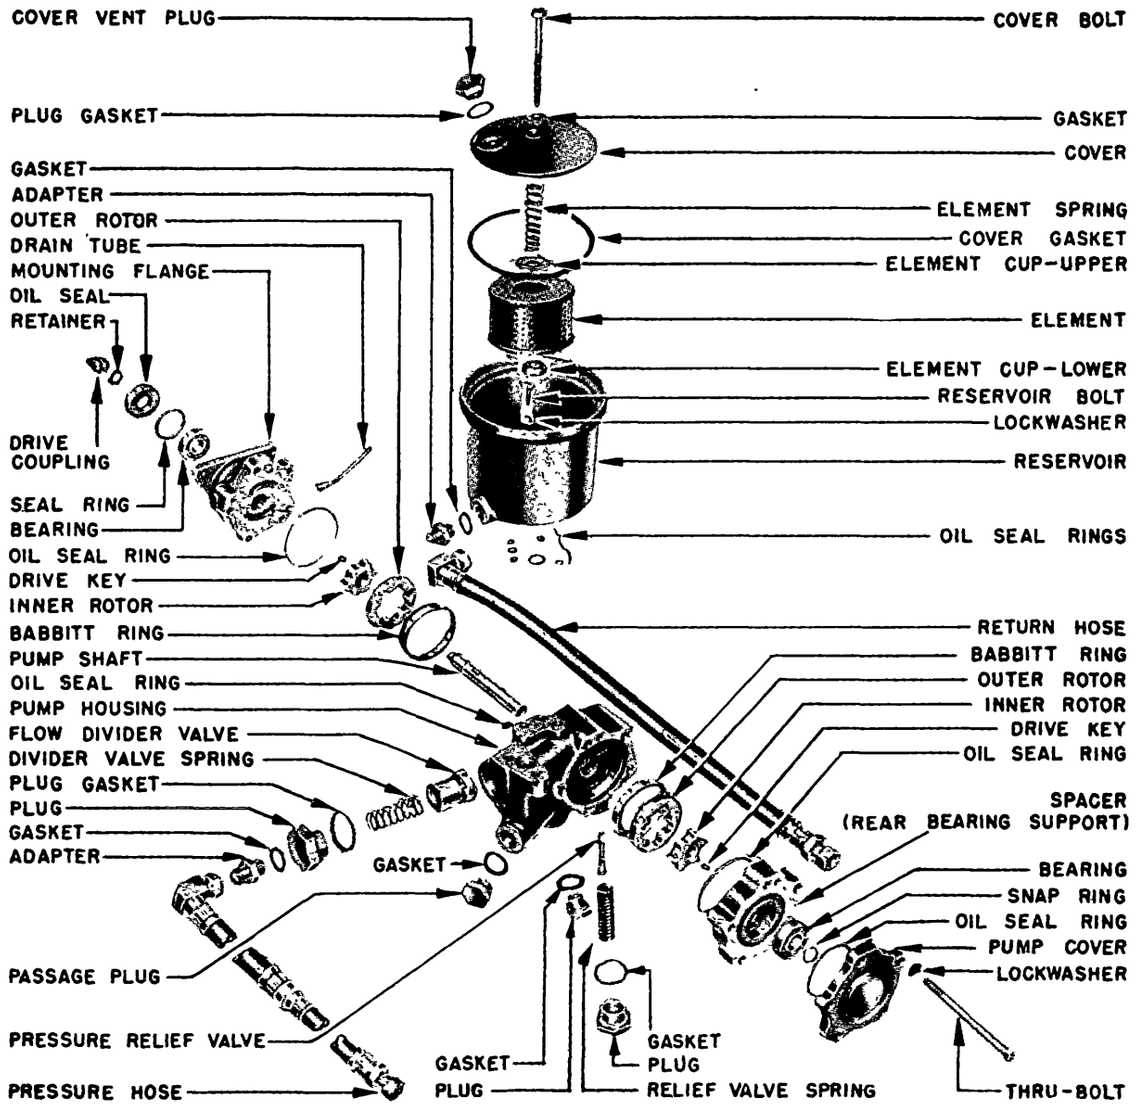
►***CAUTION—Keep each rotor set separate and re-install in same position when reassembling pump.***

5. Remove small bleed hole seal ring and large seal ring on mounting face of pump body. Discard these seals.
6. Remove bearing seals and bearing from mounting flange and rear bearing from pump spacer using Tool C-3129. Discard the oil seals.
7. **Pressure Relief Valve**—Remove 1¼" plug from bottom of pump body, lift out spring and plunger (if plunger sticks in body, rap body on wooden block to dislodge plunger).
8. **Flow Divider Valve**—Remove 1½" plug from end of pump body, remove valve spring, remove valve by inserting finger in valve skirt and pulling valve out.
9. Remove two 1" plugs and gaskets which close drilled oil passages.

Disassembly ("Single Rotor" type): Remove coupling lock screw, then remove coupling. Install pump in vise with protective copper jaws. Remove five body-to-cover attaching bolts, then remove cover. Remove shaft and rotor assembly, then "O" ring seal and "oilite" thrust washer in bottom of pump shaft hole.

Bushing & Seal Replacement—NOTE—New seal should always be installed whenever bushing replaced. Replace bushing and seals as follows:

Pump Cover Shaft Bushing—Place pump body in vise with protective copper jaws, install Tool C-3185, tap threads into bushing with outer section of tool, using an open end or adjustable wrench. After tool threaded into bushing sufficiently, screw T handle section of tool into hole until tool bottoms in cover, remove bushing. To install, drift bushing into place with Tool C-3233.



Pump Body Shaft Bushing—Place pump body in vise with protective copper jaws, mount pump cover to pump body, install attaching bolts. Install Tool C-3185 in cover bushing hole, thread tool into housing bushing, remove bushing and seal. To install, mount bushing to Tool C-3235 and drift bushing into place.

Outer Rotor Babbitt Bushing—Remove pump cover from pump body. Thread Tool C-3214 into pump body using adapter Tool C-3234, remove bushing. To install, drift bushing into place with Tool C-3251.

Pump Shaft Oil Seal Replacement—With pump body securely clamped in vise with protective copper jaws, mount seal to Tool C-3230, drive seal into place.

Cleaning & Inspection: Clean all parts thoroughly in solvent and blow dry with compressed air. Wash bearings in clean kerosene and dry by blowing air through bearing *(CAUTION*—do not spin bearing with air). Inspect bearings for wear or roughness and replace if they do not rotate freely. Inspect babbitt rings in pump body for wear or scoring. Inspect rotors and pump shaft for wear, scoring, or burrs (remove burrs with a fine stone or crocus cloth). Check end clearance of rotors by installing them in pump body and using a feeler gauge to measure clearance from rotor to straightedge placed on face of body. End clearance limits are .001-.0017" (outer rotor of double rotor pump, and rotor of sin-

CONTINUED ON NEXT PAGE

HYDRAGUIDE HYDRAULIC PUMP (DOUBLE ROTOR) AND RESERVOIR

HYDRAGUIDE (Cont.) (EXTERNAL OIL PASSAGE)

gle rotor pump), .0013-.002" (inner rotor). Check valve plunger.

NOTE—If rotors badly scored, or worn beyond limits given above, install complete new pump assembly.

Reassembly ("Double Rotor" type): Use all NEW "O" ring seals and gaskets. Lubricate bearings and all moving parts with clean SAE 10W engine oil, coat all seal rings and seals with Lubriplate when assembling. Assemble pump in following order:

1. Install front bearing in mounting flange using Tool C-3129, install oil seal ring over bearing, then drive oil seal into position over bearing and seal ring using Tool C-3129.
2. Install rear bearing in pump rear spacer using Tool C-3129.
3. Install two 1" plugs and gaskets in drilled oil passages in pump body and tighten securely.
4. Install flow divider valve plunger in pump body with ported end inward, insert spring, install plug and gasket, tighten plug to 45-50 ft.lbs.
5. Install relief valve plunger with small end inward, insert spring, install plug and gasket, tighten plug to 45-50 ft.lbs.
6. Invert pump body so that bleed hole is upward, carefully install front outer rotor *(CAUTION*—use care not to damage babbitt ring), install pump shaft with drive tongue upward through rotor and into pump body so that drive key slot is exposed above rotor, slide front inner rotor over shaft and install drive key so that rotor engages key, turn shaft until rotors mesh, slide shaft in pump body until key is centered in inner rotor.
7. Install new bleed hole seal ring and large seal ring in proper position on pump body.
8. Insert Protector Thimble, Tool C-3130, through front face of mounting flange and into front bearing oil seal until it bottoms in the flange. Install mounting flange and thimble on front of pump body *(CAUTION*—make certain that shaft engages thimble, then slide mounting flange down against pump body and remove protector thimble from end of shaft. Align locating dowel pins with holes in body and tap mounting flange with soft hammer to seat it against the pump body.
9. Turn pump over and install rear outer rotor *(CAUTION*—use care not to damage babbitt ring), slide inner rotor over end of shaft and place drive key in position in shaft slot so that rotor engages key and meshs with outer rotor.
10. Install new seal ring on pump body, slide rear spacer and bearing assembly down over shaft, align dowel pins with dowel holes and tap spacer with a soft hammer to seat it against the pump body. Install snap ring in shaft groove using Tool C-3128.
11. Install new seal ring on spacer, place rear cover in position on spacer, install through-bolts and lockwashers and tighten evenly to 15-20 ft.lbs.
12. Install coupling chamber drain tube in bottom of mounting flange, tightening the nut finger-tight and ½-¾ turns additional.
13. Install drive coupling as follows:

Rubber Type Coupling—Install driving flange on pump shaft using 5/8" diameter steel rod to seat flange *(CAUTION*—do not hammer on drive lugs). Install special lock screw and plain washer (do not use lockwasher), tighten screw to 10-15 ft.lbs.

Metal Tongue Type Coupling—Install drive coupling on shaft, install retaining ring.

Reassembly ("Single Rotor" type): Use NEW "O" ring seals and gaskets. Lubricate all parts with clean SAE 10W engine oil, coat "O" ring seals with Lubriplate. Assemble pump as follows: Install flow divider valve (ported end first) into pump body. Insert small spring plunger and ring, using Tool C-3229. Install large spring, gasket and adapter. Tighten adapter to 45-50 ft. lbs. torque. Install shaft protector thimble Tool C-3228 in pump body until tool bottoms, install rotor shaft assembly, using care not to damage babbitt bushings when installing rotor. Position "O" ring seal in body. Place cover in position, installing attaching bolts and washers. Tighten bolts to 15-20 ft. lbs. torque. Install coupling flange on pump shaft, then special lock screw and washer. Hold coupling with Tool C-3227 and tighten to 10-12 ft. lbs. torque.

Installation of Reservoir on Pump: Install one large circular section "0" ring, and five (5) small "0" rings which are used as gaskets between reservoir and pump. Install small tapered plug, Tool C-3117 and large tapered plug, Tool C-3118 into the two passage holes in bottom of reservoir. Insert the two pilots, Tool C-3116 into matching screw holes of reservoir and pump and install reservoir to pump. Install the four attaching screws and tighten to 7-12 ft. lbs. torque.

HYDRAULIC PUMP INSTALLATION:

▷*PUMP DRIVE COUPLING CAUTION*—Make certain that pump and generator have same type drive coupling. Couplings are not interchangeable and SAME TYPE PUMP AND GENERATOR MUST BE USED TOGETHER. When installing pump with rubber type coupling, make certain that rubber insulator and sleeve installed in generator drive flange.

1. Attach pump and reservoir assembly to generator, using care to index pump shaft tongue into groove of generator coupling. Tighten three pump-to-generator mounting screws to 12-17 ft. lbs. torque.
2. Attach the two hoses, using ⅜-⅝ of a turn after initial finger tightening. The constant section hose is the return line and connects to the reservoir fitting. The dual diameter hose is the pressure line and connects to the pump body fitting. *If* the hose connectors are ever removed, they should be tightened to 25-30 ft. lbs. torque.
3. Clean out reservoir with lint free, clean cloth before removing tapered plugs, Tools C-3117 & 3118. Install filter element in reservoir, and fill with SAE 10-W engine oil to 1½" below gasket seat. *See BLEEDING above.*
4. AFTER bleeding of the system completed and reservoir refilled to correct level, install reservoir cover and gasket and tighten cover bolt to 5-8 ft.lbs.

NOTE—If relief valve assembly cap removed, tighten to 5-8 ft.lbs. torque.

GEMMER HYDRAGUIDE (CHRYSLER & DESOTO) (INTERNAL OIL PASSAGE TYPE)

Chrysler, All Models (Late 1953-54)
DeSoto, All Models (1954)

▷CHANGES & CORRECTIONS

▷*1954 "HIGH SPOT" OR "LUMPY FEELING" AT OR NEAR STRAIGHT AHEAD POSITION (Or feeling of oversteering when turning from center to right or left):* Check and adjust Cross-shaft Backlash and check Steering Tube-and-Column Alignment EXACTLY as detailed below. NOTE—See 1953 Steering Column Jacket Bearing Spring Change (below).

▷*1953 STEERING COLUMN JACKET BEARING SPRING PRODUCTION CHANGE (To correct slight "lumpy" feeling): New spring, Part No. 1488451 is 2⅞" long and has 8 coils, older spring is shorter and has 5½ coils. See "Lumpy Feeling" Correction above.*

DESCRIPTION

DESCRIPTION: The "Internal Oil Passage" Power Steering Gear is of the same basic design and operates on the same principle as the previous Gemmer Hydraguide type. The new type has numerous structural changes:

Gear Housing—Cast aluminum (was malleable iron). Oil passages are provided in the housing and all external oil tubing and connections have been eliminated.

Power Cylinders—Cylinders are gray iron castings with integral mounting flange and are attached by capscrews. No piston travel adjustment is required.

Valve Body & Valve Body Cap—Both parts are die-cast aluminum. Valve identification is stamped on valve body above each valve cylinder.

Power Piston Assembly—Two piece aluminum die-cast type with new seal ring assemblies (rectangular section rubber seal ring backed up by molded nylon ring). *NOTE*—Piston assembly is interchangeable with previous type used in earlier model steering gears.

Worm Adjustment—Threaded type adjustment screw and locknut provided in worm shaft lower cover (replaces adjusting shims).

Worm Lubrication—Entire steering gear (including worm and roller now lubricated by SAE 10-W Engine Oil (used for both lubrication and hydraulic power). Nylon Elastic Stop Nuts and nylon washers are used on both the worm and shaft adjusting screws for sealing at these points.

▷*INSTALLATION OF INTERNAL OIL PASSAGE STEERING GEAR ON PREVIOUS CHRYSLER MODELS:* This gear can be installed on early 1953 cars by installing a new bracket or by shimming or reworking the present bracket to eliminate interference under extreme alignment conditions. *THIS GEAR CANNOT BE USED ON CARS PRIOR TO 1953 MODELS.*

Hydraulic Pump & Reservoir Assembly: "Single Rotor" type mounted on generator and driven by armature shaft. *See Hydraulic pump data in "Gemmer Hydraguide (External Oil Passage Type)".*

LUBRICATION: *CAUTION—New "Internal Oil Passage" type is lubricated entirely by the hydraulic pressure oil supply and special lubricant not required for steering gear worm-and-roller (as on previous External Oil Tube type).*

Checking Fluid Level: Check at 1000 mile intervals or every 30 days. Thoroughly clean top of reservoir,

CONTINUED ON NEXT PAGE

HYDRAGUIDE (C nt.) (INTERNAL OIL PASSAGE)

remove cover. Add oil as required to maintain level even with mark stamped on inside of reservoir or ½" above top of filter element.

Recommended Oil—SAE. 10W (MM or MS). For temperatures below —10°F., use SAE. 5W.

BLEEDING HYDRAULIC SYSTEM: *See ADJUSTMENTS under "Gemmer Hydraguide (External Oil Passage Type)."*

HYDRAULIC PRESSURE TEST: *See "Gemmer Hydraguide (External Oil Passage Type)".*

BELT ADJUSTMENT: Keep generator drive belt in adjustment (¾" deflection midway between fan and generator pulleys).

ADJUSTMENT

All adjustments are made with Steering Gear Unit off car. *See "Overhaul" for adjustments with Steering Gear off Car.*

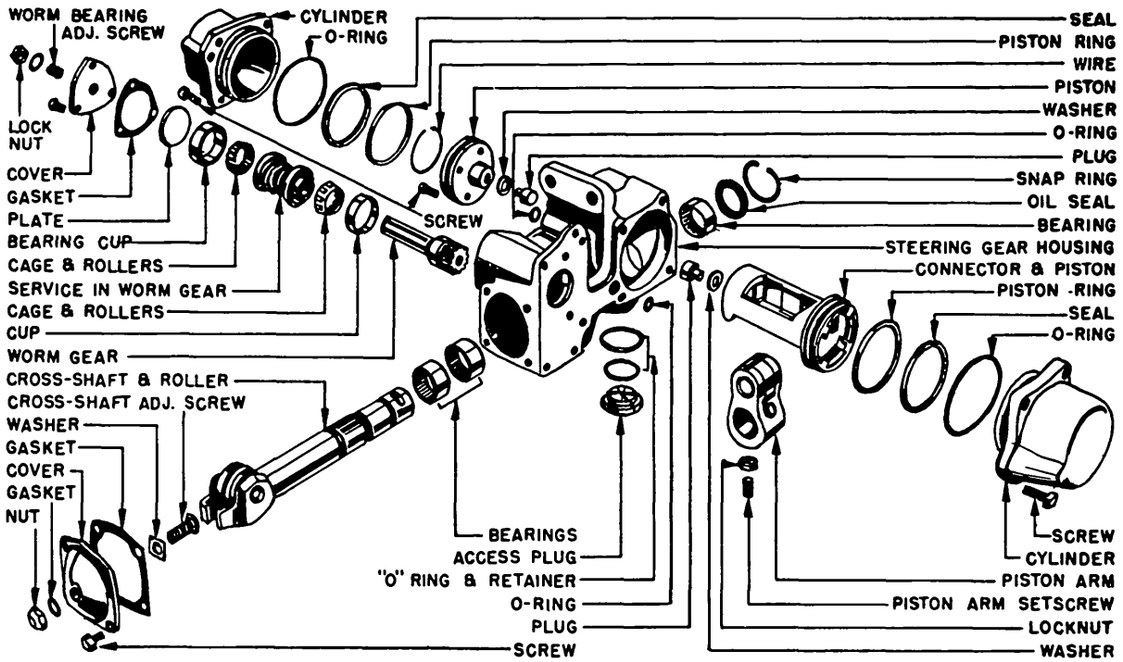
STEERING COLUMN HORIZONTAL & VERTICAL ALIGNMENT: If spacing between column and chuck is not equal, loosen bracket-to-frame bolts and shift chuck and bracket in required direction to equalize the spacing between column jacket base, grommet, and valve body face. *CAUTION*—In some instances it may be necessary to install shims between bracket and frame to obtain sufficient movement of gear for proper alignment. Shims should be "U" shaped or flat washers and placed around bracket-to-frame bolts. *DO NOT PLACE SHIMS BETWEEN GEAR AND BRACKET.*

TROUBLE SHOOTING: *See "Gemmer Hydraguide (External Oil Passage Type)"*

STEERING GEAR REMOVAL

STEERING WHEEL & HORN BUTTON REMOVAL: Disconnect battery, center steering wheel in straight-ahead position. Press down on horn blowing ring ornament and turn counter-clockwise. Lift out ornament retaining spring and pad. Disconnect horn wire from terminal on travel plate and insulator assembly. Remove bushing, travel plate, horn blowing contact ring spring and triangular ground plate. Curl and push horn wire into steering gear tube to make room for steering wheel puller pilot. Remove steering wheel nut. Attach puller Tool C-612 and remove steering wheel.

STEERING GEAR ASSEMBLY REMOVAL: (1)—Remove horn blowing ring, turn steering wheel to extreme left position, and remove steering wheel. Remove transmission position indicator lamp housing from gearshift lever housing. Remove snap ring retaining turn signal and carefully work turn signal switch housing upward until it clears column jacket. Remove cross head screws retaining upper and lower halves of shifting yoke collars together and lift off upper collar. Remove large Oilite bearing with care. Remove snap ring retaining shift lever yoke and bushings in gear shift tube.



(2)—Lift shift lever yoke upward and out of housing. Do not drop yoke bushings in tube. Otherwise it will be necessary to disassemble column jacket in order to recover bushings. Remove lower collar from steering column jacket.

(3)—Remove steering column jacket toe pad, floor mat, clutch, and brake pedal pads. Remove clutch and brake pedal floor pan toe board cover. Remove clutch pedal horseshoe lock, slide pedal sideways and toward rear of car to allow for clearance of steering assembly removal.

(4)—Remove shift linkage clevis pin from bellcrank assembly in engine compartment. Disconnect directional signal indicator wires and remove horn wire connector from steering column. Remove two steering column to instrument panel screws.

(5)—Remove column jacket shroud assembly by removing column and shroud assembly down and away from gear chuck. Disconnect pressure and return hose from steering gear housing assembly, and cap the fittings.

(6)—Raise car off floor and remove left front wheel and drag link. Remove fender side shield. Remove steering gear chuck-to-frame bracket attaching capscrews. Install front wheel, lower car and remove steering gear assembly through toe board opening.

GEMMER HYDRAGUIDE STEERING GEAR & POWER UNIT

STEERING GEAR OVERHAUL

►*DISASSEMBLY NOTE*—Drain assembly by removing piston arm screw access plug at bottom center of cylinder housing. Remove caps from inlet and outlet oil passages. Turn steering gear coupling to extreme right and left, while draining oil, to force out all oil. Thoroughly clean all surfaces of unit.

DISASSEMBLY (Valve Assembly & Steering Gear Tube): (1)—Remove capscrew from steering arm and remove arm from steering cross shaft. Remove four bolts attaching valve body and valve cap assembly to housing, and lift valve body and cap from housing. *(CAUTION*—Valve body is made of die-cast aluminum and must be handled carefully to prevent damage to cover or its mating surfaces). Remove five "O" ring oil seals from valve body face.

►*VALVE REMOVAL CAUTION*—Each valve body port boss is marked to aid in reassembly of valves in correct position. Work carefully when removing valves, as internal parts of valves may become loose and fall into housing. To prevent improper assembly, units of valve assemblies should be cleaned separately and placed in separate containers. *Valve parts are a select fit with each other and are not interchangeable.*

(2)—Remove outer snap ring retaining each valve assembly in valve body, and pry out each valve assembly.

►*VALVE POSITION IDENTIFICATION MARK CAUTION*—Valve position identification marks on valve body port bosses indicate the number of "O" ring seals used on each valve as follows: (a) Right Turn Reaction Valve (Lower Right)—two "O" rings. (b) Left Turn Distributor Valve (Lower Left)—three "O" rings. (c) Left Turn Reaction Valve (Upper Right)—two "O" rings. (d) Right Turn Distributor Valve (Upper Left)—three "O" rings.

►*VALVE INTERCHANGE NOTE*—Right and left valves are interchangeable as an assembly, if correct number of "O" ring seals are installed on valves for each location.

(3) Remove valve piston assembly from valve sleeve and remove check valve. Inspect valve balls, springs and valve body bleed holes for obstructions. Clean all parts in solvent and replace "O" ring oil seals. Assemble valves in sleeves, making sure each valve is clean and is assembled in its respective position in valve sleeve. Remove the six valve body cap recessed head screws and star washers. Remove valve body cap and gasket from valve body housing.

(4)—Clamp steering tube coupling in vise and remove capscrew and washer holding coupling to

CONTINUED ON NEXT PA E

HYDRAGUIDE (Cont.) (INTERNAL OIL PASSAGE)

steering shaft.

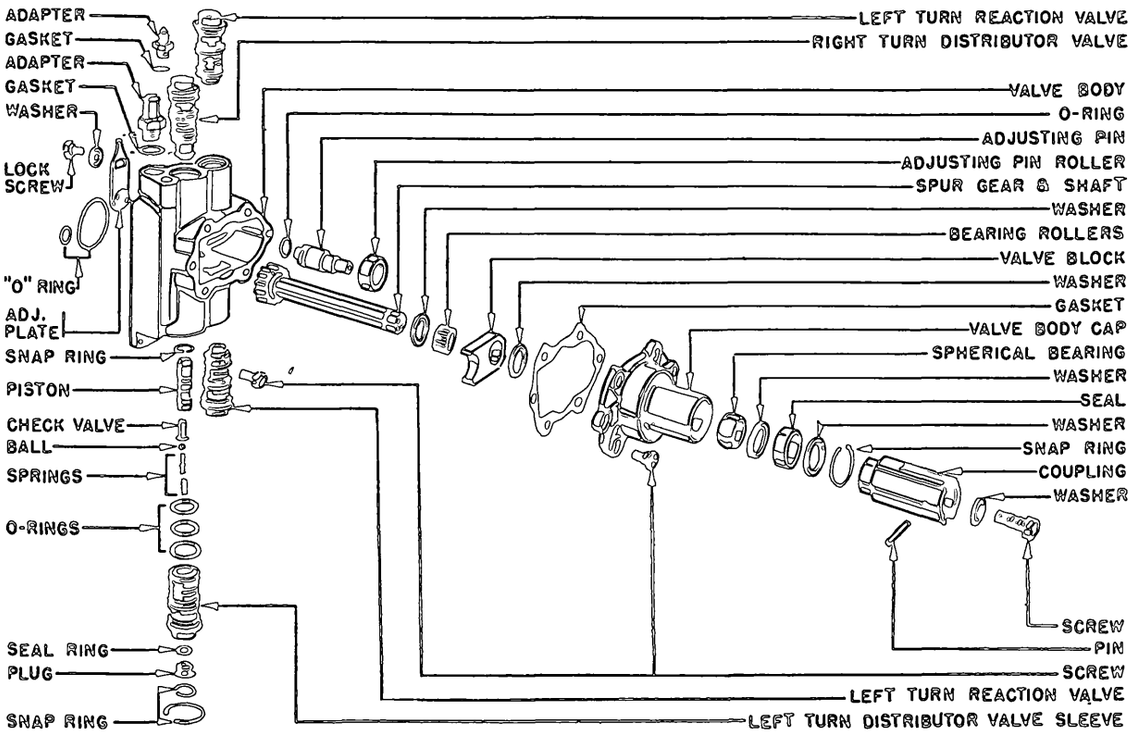
▷*CAUTION—Do not clamp tube gear or valve cap body casting in vise. Clamp only the coupling to prevent damaging the assembly.*

(5)—Mount Puller Tool C-3132 (adapted to C-293 puller stand) to valve body cap and steering gear tube coupling assembly. Clamp puller in vise and remove coupling from gear tube. Slide steering gear tube and valve block assembly out of valve body cap. Remove oil seal snap ring and lift out oil seal outer washer.

(6)—With Remover & Installer Tool C-3269, drive the spherical bearing, steering gear tube oil seal and inner washer from valve body cap. Inspect bearing, roller, and valve block for damage, and wear. Clean all parts with solvent and blow dry with air.

Steering Gear Cylinders and Power Pistons: (1)—Remove cylinder-to-housing attaching capscrews. Thread cylinder removing studs, Tool C-3336 evenly into threaded cylinder flange holes until studs bottom in housing. Continue threading studs inward, evenly, until cylinder is free from housing. Remove large "O" ring seal from outer machined surface of cylinders, and small "O" ring seals from steering gear housing face.

(2)—Center piston arm in center of steering housing and remove piston screw retaining wire from pistons. Remove three piston-to-connector attaching capscrews and remove piston from connector. Remove connector and piston assembly from housing. Remove the neoprene seals and nylon thrust rings frim pistons. Carefully inspect rings for damage.



▷*PISTON RING CAUTION—If piston rings are damaged or appear to be in doubtful condition, rings should be replaced.*

(3)—Loosen piston setscrew locknut and remove setscrew. Remove steering gear shaft cover adjusting screw locknut and nylon washer. Turn steering gear shaft to center position. Remove the four shaft cover attaching capscrews and copper sealing washers. Withdraw steering shaft from housing sufficiently to allow for removal of cover. Turn shaft cover adjusting screw in. Slide adjusting screw and cover out of slot in end of shaft. Remove cover and gasket. NOTE—A nylon washer is being used instead of the adjusting screw star washer.

(4)—Withdraw steering shaft from piston arm and remove piston arm assembly from steering gear housing. Loosen worm gear shaft cover adjusting screw locknut. Remove the three cover attaching screws and lift cover and screws from housing. Remove the steering gear shaft outer oil seal retaining snap ring with Remover Tool C-3137. Remove outer oil seal.

(5)—Remove the thrust pad, cup bearing, and worm assembly from housing. Remove adjusting screw locknut, nylon washer, and adjusting screw from worm cover. Clean housing and parts thoroughly in solvent and blow dry with air. Inspect worm shaft and gear, bearings, cups, bearing rollers, and other parts.

(6)—Inspect the three steering shaft needle bearings in housing. If rollers do not rotate freely, or if bearings are damaged, remove steering shaft center and inner bearings by driving bearings toward outer bearing with Tool C-3114. Remove outer bearing by driving bearing toward inside of steering gear with Driver Tool C-3113.

GEMMER HYDRAGUIDE CONTROL VALVE ASSEMBLY

REASSEMBLY (Steering Gear Cylinders and Power Pistons): (1)—When installing steering gear shaft bearings in steering housing, bearings should be always driven against lettered end of bearing cage. Install center bearing in housing from steering gear arm side of housing. Drive bearing into housing with Driver Tool C-3114, until bearing is flush with inner face of housing.

(2)—Install shaft outer bearing, drive bearing with Driver C-3113, until bearing is approximately .050" below outer seal counter bore of housing.

(3)—Lubricate worm gear bearings and cups with lubriplate. Install worm gear, outer bearing, cup and thrust pad in housing. Lubricate gasket with Lubriplate and install gasket in position in housing. Remove adjusting screw from worm gear cover and place cover on steering housing. Install the three cover attaching capscrews, with copper sealing washers under screw heads. Tighten to 20 ft. lbs. Install adjusting screw in cover, nylon washer and locknut on adjusting screw. Turn locknut down until it barely touches the washer.

Worm Shaft Bearing Adjustment—Turn adjusting screw clockwise until worm rotates freely without binding from one extreme to opposite extreme. *(CAUTION—The worm gear when properly adjusted, should rotate freely in bearing cones without binding, and should also be sufficiently tight to eliminate any free play between shaft and bearings).* Hold adjusting screw and tighten locknut to 25 ft. lbs. Recheck worm shaft bearing adjustment after tightening adjusting screw and locknut.

Checking Piston Arm and Plug Clearance—Assemble piston on piston connector outside of steering housing. Check clearance between piston plugs and piston arm roller. *It is important that this clearance be held as close to zero as possible.* This can be controlled by various thickness of shims inserted between piston and piston plugs. These shims are available for service in a number of sizes varying in steps of .001" thickness. After checking the above clearance, disassemble piston and connector, leaving plugs in piston. Remove connector from piston arm.

(4)—Make sure steering shaft rollers rotate freely and that the housing oil passages and piston arm are clean. Place piston arm in position in housing so that splines on shaft will mesh with splines on piston arm. Insert steering shaft into piston arm until shaft is positioned in housing.

(5)—Install steering gear shaft cover gasket on housing after coating with Lubriplate. Install steering gear shaft cover and adjusting screw assembly in slot in end of shaft. Turn adjusting screw counter-clockwise to draw shaft cover up to housing. When cover is properly seated on housing, install the four cover attaching capscrews and copper sealing washers under head of each screw. Tighten screws evenly to 20 ft. lbs. Install nylon washer and locknut on shaft adjusting screw until nut barely touches nylon washer. Install gear shaft outer oil seal (lip of seal facing inside housing) with Sleeve

CONTINUED ON NEXT PAGE

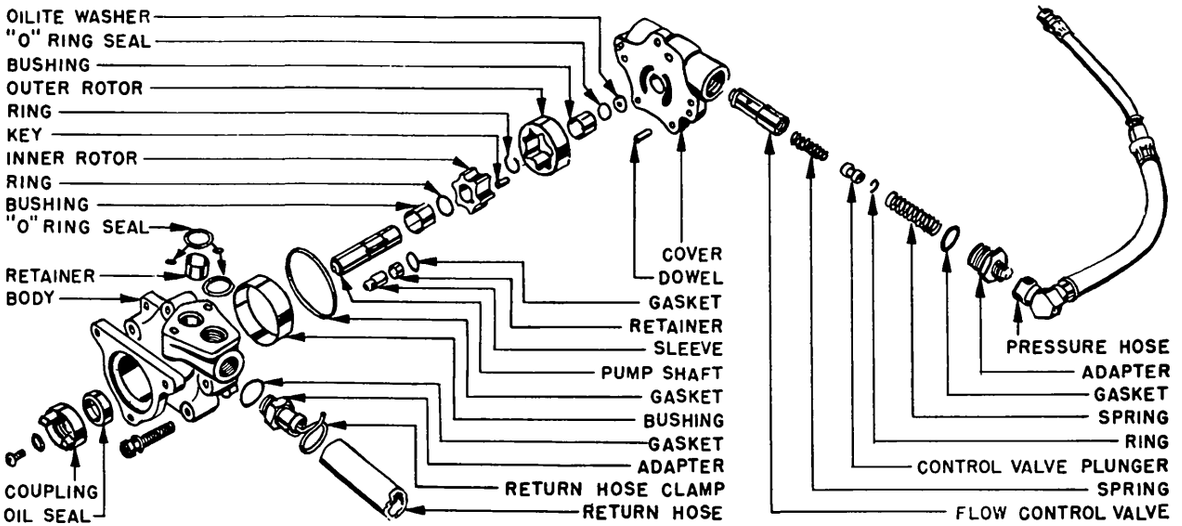
HYDRAGUIDE (C nt.) (INTERNAL OIL PASSAGE)

Tool C-3136. Install outer seal snap ring (beveled side out). Position snap ring so that ring opening is pointing downward toward bottom of unit so that snap ring can be removed readily from under car when necessary. Make sure snap ring is properly seated in groove. Install steering gear arm on steering shaft. Tighten arm clamp bolt to 200 ft. lbs.

Steering Gear Shaft Adjustment—***(CAUTION—When making cross shaft adjustment, always remove power arm access plug and loosen power arm set screw before attempting to adjust cross shaft).*** Set worm gear and piston arm at center position. Hold worm at center with one hand. With other hand on pitman arm, check backlash between gear and worm in both directions. Turn shaft adjusting screws so that no backlash will be felt while worm is turned approximately 45 degrees, either side of center line.

►***CAUTION: Clearance should be at a minimum at the degree positions without binding. Do not adjust cross shaft roller and worm too tightly.***

Hold adjusting screw in the adjusted position and tighten locknut to 20-25 ft. lbs. Install piston arm adjusting lock screw and locknut. Tighten screw to 30-35 ft. lbs. and tighten locknut to 20 ft. lbs. Lubricate and install a new "O" ring seal on access plug, and tighten plug to 35 ft. lbs.



(6)—Center piston arm in steering housing. Install piston and piston connector assembly in housing, with piston plug bearing against piston arm and roller. Assemble the removed piston and plug assembly to opposite side of piston connector. Tighten Allen screws to 16-20 ft. lbs. Install piston screw retaining lock wires. *CAUTION*—New "O" ring seals, gaskets, copper and nylon washers should be used each time unit is disassembled.

(7)—Lubricate neoprene "D" ring (cross section of ring is shaped like a "D"), and nylon thrust rings on piston with Lubriplate. Make sure that tapered side of thrust ring fits against tapered side of piston ring groove.

►***NOTE: Tapered side of thrust ring fits against tapered side of piston ring groove.***

(8)—Remove cylinder removal screws from cylinder flange, check face for burrs, clean and lubricate cylinder bores. Lubricate cylinder "O" ring with Lubriplate and install ring on outer machined section of cylinder. Install oil passage "O" rings on housing-to-cylinder oil passages. With pistons located in center of housing, place cylinders in position on housing. Work carefully to avoid damaging "O" rings during installation. Align cylinder holes with holes in housing. Install capscrews and tighten screws evenly to 30-40 ft. lbs.

Valve Assembly & Steering Gear Tube: (1) Install spherical bearing in valve body cap and place oil seal inner washer in body against bearing. Lubricate steering tube gear oil seal with Lubriplate and install seal in valve body (with lip of seal inward). Using Remover & Installer Tool C-3269, drive seal in valve body cap sufficiently to allow for installation of outer washer and snap ring. Install oil seal outer washer and snap ring, making sure snap ring is properly seated in valve body cap. Place steering gear tube and valve block assembly in valve body cap. Install coupling on steering tube gear and secure with capscrew and washer. Tighten screw to 20 ft. lbs.

HYDRAGUIDE HYDRAULIC PUMP (SINGLE ROTOR TYPE)

►***VALVE BLOCK ADJUSTING PIN NOTE***—To replace or inspect needle roller bearings in adjustment pin roller, lift bearing and roller off pin as an assembly from shaft. To replace needle bearing in roller, use one end of Driver Tool C-3141 to remove bearing and the other end to install bearing. If leakage around valve block adjusting pin is apparent, remove adjusting plate capscrew, washer and adjusting plate. Remove valve block adjusting pin from inside valve body and remove "O" ring seal from adjusting pin. Lubricate new ring seal with Lubriplate and install ring on adjusting pin. Install pin in valve body. Do not damage ring when installing. ***(CAUTION—When assembling valve block adjusting pin in valve body, locate offset side of pin away from steering tube gear. The adjusting plate should not be installed on adjusting pin until unit is completely assembled).*** Inspect steering tube gear thrust button located in valve body for wear and replace if necessary.

(2)—Place adjusting pin roller on pin and lubricate valve body cap gasket. Install valve body cap assembly on valve body. Install the six recessed head screws and star washers in valve body cap. Tighten screws to 20 ft. lbs.

(3)—Lubricate "O" rings on valve assemblies with Lubriplate and install valves as indicated on valve body ports. Install snap rings with beveled edge out. Make sure snap rings are properly seated in grooves. Lubricate the five valve body-to-housing "O" ring seals and locate them in valve body.

(4)—Set worm gear and piston arm to center position. Locate steering tube coupling slot in vertical position and assemble valve body to steering gear housing. Install valve body to housing attaching screws and lockwashers. Tighten screws to 40 ft. lbs.

Spur Gear Adjustment (Unit off Car)—With worm gear and piston arm centered, turn tube coupling slot in vertical position. Install adjusting plate on adjusting pin. Rotate adjusting pin and plate until no backlash is felt at steering tube coupling. Hold lock plate in adjusted position. Install and tighten capscrew to 12 ft. lbs.

STEERING GEAR INSTALLATION

STEERING GEAR ASSEMBLY INSTALLATION: Reverse removal procedures.

HYDRAULIC PUMP OVERHAUL

HYDRAULIC PUMP REMOVAL: Disconnect the two hoses from pump reservoir assembly and catch oil from pump in a drain pan. Tie the loose ends of hoses out of the way above steering gear assembly to prevent loss of oil. Cover the ends of both hoses. Remove the three pump-to-generator screws and remove pump (*CAUTION*—do not lose coupling insulator and sleeve on pumps with rubber coupling).

Removal of Reservoir From Pump:

1. Remove cover assembly from reservoir, lift out filter element and drain oil from reservoir.
2. Install the small tapered plug Tool C-3117 and the large tapered plug Tool C-3118, into the two holes that permit passage of oil to pump (this will prevent dirt entering pump).
3. Remove the four reservoir-to-pump attaching screws and lift reservoir from pump, being sure not to lose one large rubber "O" ring and five small rubber "O" rings which are used as gaskets between pump and reservoir.

OVERHAUL OF PUMP: *CAUTION*—Cleanliness is extremely important when working on hydraulic pump. Pump should be thoroughly cleaned before disassembling, work bench should be covered with clean paper, and all parts should be kept in clean kerosene until reassembled to protect them from dirt and corrosion.

Disassembly ("Single Rotor" type): Remove coupling lock screw, then remove coupling. Install pump in vise with protective copper jaws. Remove five body-

CONTINUED ON NEXT PA E

HYDRAGUIDE (Cont.) (INTERNAL OIL PASSAGE)

to-cover attaching bolts, then remove cover. Remove shaft and rotor assembly, then "O" ring seal and "oilite" thrust washer in bottom of pump shaft hole.

Bushing & Seal Replacement—NOTE—New seal should always be installed whenever bushing replaced. Replace bushing and seals as follows:

Pump Cover Shaft Bushing—Place pump body in vise with protective copper jaws, install Tool C-3185, tap threads into bushing with outer section of tool, using an open end or adjustable wrench. After tool threaded into bushing sufficiently, screw T handle section of tool into hole until tool bottoms in cover, remove bushing. To install, drift bushing into place with Tool C-3233.

Pump Body Shaft Bushing—Place pump body in vise with protective copper jaws, mount pump cover to pump body, install attaching bolts. Install Tool C-3185 in cover bushing hole, thread tool into housing bushing, remove bushing and seal. To install, mount bushing to Tool C-3235 and drift bushing into place.

Outer Rotor Babbitt Bushing—Remove pump cover from pump body. Thread Tool C-3214 into pump body using adapter Tool C-3234, remove bushing. To install, drift bushing into place with Tool C-3251.

Pump Shaft Oil Seal Replacement—With pump body securely clamped in vise with protective copper jaws, mount seal to Tool C-3230, drive seal into place.

Cleaning & Inspection: Clean all parts thoroughly in solvent and blow dry with compressed air. Wash bearings in clean kerosene and dry by blowing air through bearing *(CAUTION—do not spin bearing with air)*. Inspect bearings for wear or roughness and replace if they do not rotate freely. Inspect babbitt rings in pump body for wear or scoring. Inspect rotors and pump shaft for wear, scoring, or burrs (remove burrs with a fine stone or crocus cloth). Check end clearance of rotors by installing them in pump body and using a feeler gauge to measure clearance from rotor to straightedge placed on face of body. End clearance limits are .001-.0017" (outer rotor of double rotor pump, and rotor of single rotor pump), .0013-.002" (inner rotor). Check valve plunger.

NOTE—If rotors badly scored, or worn beyond limits given above, install complete new pump assembly.

Reassembly ("Single Rotor" type): Use NEW "O" ring seals and gaskets. Lubricate all parts with clean SAE 10W engine oil, coat "O" ring seals with Lubriplate. Assemble pump as follows: Install flow divider valve (ported end first) into pump body. Insert small spring plunger and ring, using Tool C-3229. Install large spring, gasket and adapter. Tighten adapter to 45-50 ft. lbs. torque. Install shaft protector thimble Tool C-3228 in pump body until tool bottoms, install rotor shaft assembly, using care not to damage babbitt bushings when installing rotor. Position "O" ring seal in body. Place cover in position, installing attaching bolts and washers. Tighten bolts to 15-20 ft. lbs. torque. Install coupling flange on pump shaft, then special lock screw and washer. Hold coupling with Tool C-3227 and tighten to 10-12 ft. lbs. torque.

Installation of Reservoir on Pump: Install one large circular section "O" ring, and five (5) small "O" rings which are used as gaskets between reservoir and pump. Install small tapered plug, Tool C-3117 and large tapered plug, Tool C-3118 into the two passage holes in bottom of reservoir. Insert the two pilots, Tool C-3116 into matching screw holes of reservoir and pump and install reservoir to pump. Install the four attaching screws and tighten to 7-12 ft. lbs. torque.

HYDRAULIC PUMP INSTALLATION:

▷*PUMP DRIVE COUPLING CAUTION*—Make certain that pump and generator have same type drive coupling. Couplings are not interchangeable and SAME TYPE PUMP AND GENERATOR MUST BE USED TOGETHER. When installing pump with rubber type coupling, make certain that rubber insulator and sleeve installed in generator drive flange.

1. Attach pump and reservoir assembly to generator, using care to index pump shaft tongue into groove of generator coupling. Tighten three pump-to-generator mounting screws to 12-17 ft. lbs. torque.

2. Attach the two hoses, using ⅜-⅝ of a turn after initial finger tightening. The constant section hose is the return line and connects to the reservoir fitting. The dual diameter hose is the pressure line and connects to the pump body fitting. If the hose connectors are ever removed, they should be tightened to 25-30 ft. lbs. torque.

3. Clean out reservoir with lint free, clean cloth before removing tapered plugs, Tools C-3117 & 3118. Install filter element in reservoir, and fill with SAE 10-W engine oil to 1½" below gasket seat. *See BLEEDING above.*

4. AFTER bleeding of the system completed and reservoir refilled to correct level, install reservoir cover and gasket and tighten cover bolt to 5-8 ft.lbs.

NOTE—If relief valve assembly cap removed, tighten to 5-8 ft.lbs. torque.

CHRYSLER, DE SOTO, DODGE, PLYMOUTH "CO-AXIAL"

Chrysler (1954-55)
DeSoto (1954-55)
Dodge (1955)
Plymouth (1955)

▷CHANGES & CORRECTIONS

▷*GEARSHAFT PRODUCTION CHANGE & ADJUSTMENT CAUTION:* Early cars (prior to approximately Jan. 1955) have a gearshaft with teeth having unequal widths. Later cars, have a gearshaft with teeth of equal width. The later type shaft is identified by a "O" stamped on the steering arm end of the shaft, and is adjusted in a different manner than the early type shaft.

▷*1955 POWER STEERING PISTON PRODUCTION CHANGE:* Effective production March 18, 1955 a new type piston has been used. New piston has a narrow ring groove, a "D" type ring seal, Part No. 1634561, and eliminates the use of a steel ring. Kit, Part No. 1692656, is available to service earlier type piston with "L" type piston ring and steel ring. New "D" type seal should be used to correct a "lack of feel" condition.

▷*1955 DODGE JERKY OPERATION OF POWER STEERING GEAR CORRECTION:* After generator drive belt has been adjusted (See Generator on Car Page), adjust fan drive belt so that a maximum of 1/4" deflection is obtained when applying a 10 lb. pull with spring scale at middle of widest belt span.

DESCRIPTION

Components of this system have been fitted into an elongated, tubular-shaped housing, concentrically located about the axis of the steering column. Unit fastens to steering column at underside of instrument panel and extends down through firewall to a bracket bolted to top of frame. System incorporates a worm and worm connector and a rack and sector gear. Worm and worm connector acts in a manner similar to a bolt and nut assembly with left hand threads. Rotation of the worm causes linear (axial) motion of the worm connector. Fastened to worm connector, in succession, are an upper piston rod, piston, and a lower piston rod, all concentric to the steering column axis. A rack, machined in the lower portion of the lower piston rod, meshes with a sector gear. This combination produces rotation of the steering gear arm, actuating steering linkage. The conventional system of steering linkage is used. Hydraulic elements of the system include:

Hydraulic Power Mechanism—Consists of a double-acting piston, a spool valve (which fits inside the piston), and an hydraulic reaction chamber (which gives the driver the "feel" of the road). Axial positioning of the valve directs high pressure oil to one side or the other of the double-acting piston. At the same time, valve movement opens an oil return line which carries oil from low pressure side of the piston to the oil reservoir. The direction of oil flow (which depends on direction of steering wheel rotation) is such that hydraulic force is added to the driver's effort and is transmitted through the rack and sector gear to the steering gear arm.

Pump and Reservoir Assembly—Consists of generator driven oil pump with pressure relief valve and flow control valve, and a filter with oil reservoir. Flow control valve limits oil flow to a predetermined maximum (2 gallons per minute) and thus holds the horsepower required to drive the oil pump to a minimum.

ADJUSTMENT

SELECTOR LEVER & TRANSMISSION SHAFT LINKAGE: Loosen gear shift rod lever clamp bolt. Position

CONTINUED ON NEXT PAGE

"CO-AXIAL" (C ntinued)

selector lever in low or reverse, then holding the gear shift rod lever and spacer flush against gear housing, tighten nut. Place selector lever pointer lever in neutral position on indicator dial at top of steering column. Disconnect gearshift control rod at bellcrank on transmission. Make sure manual control lever (at the transmission) is in neutral position (second detent position from rear of vehicle). With selector lever pointer still in neutral position, adjust the gearshift control rod to the required length for a free fit in the lever of the bellcrank, then reinstall rod. Operate selector lever through all indicator positions. Road test vehicle.

1954 MODELS

GEAR SHAFT ONLY (UNIT IN VEHICLE): Remove drag link from steering gear arm. One man should be seated in vehicle to turn steering wheel and record positions while the other does the adjusting. Start engine and turn steering wheel from one extreme position to the other, and count the number of turns (this should be approximately 3 3/4 turns). Then, starting with steering wheel setting at one end of the travel, turn it back approximately 1 7/8 turns (center position). The steering gear shaft, when correctly adjusted, will have an arc of no backlash for at least 300° but less than 340° (or 150° either side of center). When making this adjustment, it has been found to be more accurate to turn the gear into a backlash position and adjust gear mesh to a point where backlash disappears. As an aid in establishing the 150° positions of the steering wheel when making the gear shaft adjustment, it is suggested that the clock system be used. In using system 12 o'clock would represent center position and each hour would represent 30°; therefore the 150° position would be at 5 o'clock if steering wheel was turned to right (clockwise). If turned in the opposite direction (counter-clockwise) from 12 o'clock, the 150° point would be at 7 o'clock. With steering gear in centered position, turn steering wheel to 150° (5 o'clock) and adjust, if necessary, into a backlash position. Then, using steering gear arm for checking, reduce backlash to zero at the 150° (5 o'clock) point.

►*CAUTION: When checking for no backlash, use a very light (feather) touch with a slight wrist motion. Greater effort to move the steering gear arm back and forth when checking may result in moving other parts of the gear and give a false sense of true gear shaft to rack clearances. To further aid the sense of touch, a pair of vise grips may be clamped onto the steering gear arm.*

Again with steering gear in centered position, turn the steering wheel in the opposite direction (counter-clockwise) past the 150° (7 o'clock) point into backlash position. Then turning the steering wheel back slowly toward center and using steering gear arm, check for point at which backlash disappears. If it disappears at the 150° (7 o'clock) point, the steering gear is properly centered and adjusted to the center of no backlash arc. If backlash did not disappear until after the 150° (7 o'clock) point, the steering gear is too loose and gear not properly centered to no backlash arc. To center a gear in this condition with the center of no backlash arc, the jacket and shroud assembly will have to be removed and position of tube coupling on worm shaft changed as follows: Turn coupling back to center position. Then divide the difference of 60° (2 hours 7 to 9) in half, which would be 30° (1 hour). Since the shorter distance of no backlash travel was in a counter-clockwise direction, remove coupling from worm shaft and turn it clockwise 30° (1 hour) so that when reinstalled the slot in the coupling will be 1 o'clock. Then turn coupling to 12 o'clock and gear will be centered to center of no backlash arc. Again starting from center, turn the coupling to 150° (5 o'clock) and adjust into a backlash position. Then, using steering gear arm for checking, reduce backlash to zero at the 150° (5 o'clock) point.

►*CAUTION: Too loose adjustment will result in free play and a noisy gear. Too tight an adjustment will affect recoverability and will cause excessive wear of the gear teeth.*

Recheck adjustment by turning coupling counter-clockwise past the 150° (7 o'clock) point in the backlash position. Turn coupling back slowly toward center and backlash will disappear at the 150° (7 o'clock) point if coupling was properly centered to center of no backlash arc. (NOTE—If backlash had disappeared at 6 o'clock instead of 7 o'clock it would have indicated 330° of no backlash arc, which is permissible, and position of coupling would not necessarily have to be changed. Should it be desired that the position be changed, make sure that slot in coupling, when installed, is relative to the center of no backlash arc and not the overall travel (3 3/4 turns of the steering gear). When adjustment is completed, stop engine and tighten adjusting screw locknut to 40 ft. lbs. torque. Install drag link to steering gear arm and tighten nut to 45-75 ft. lbs. torque. Check centered position of steering wheel with straight-ahead position of front wheel. If not centered properly, correct by adjusting tie rod ends.

CONTROL VALVE: *CAUTION—Since considerable effort is involved in adjusting the control valve, it is suggested that it be certain that the difficulty lies within the control valve before making the adjustment. If diagnosis indicates that gear assembly is not centered hydraulically, and all other possibilities have been checked, then proceed as follows:*

1) Remove steering gear assembly (See "Removal & Installation").

2) Remove worm housing filler plug and drain lubricant through filler hole. Attach holding fixture C-3323 to unit and place in vise. Remove tube coupling screw, lockwasher and washer from center of coupling. Using tool C-3392, remove coupling from worm shaft. (*NOTE*—Tool C-3112 may also be used to remove coupling. However, to accomplish this, necessitates the cutting of one adapter plate SP-1409 in half and using the two pieces instead of the two plates). Remove worm housing oil seal.

3) Unlock bearing adjusting nut by bending tang of lockwasher. (NOTE—Only one tang locks nut in position). Place tool C-3320 over worm shaft followed by C-3319. Holding worm stationary remove worm bearing adjusting nut, lockwasher and thrust washer. Remove worm outer bearing race and bearing roller from worm. Remove the three worm-to-gear housing screws and belleville washers. (NOTE—Concave side of washers are against housing when installed). Remove worm housing and "O" ring.

►*CAUTION: Do not bottom w rm shaft in th outward direction when removing or installing. Bott ming the worm shaft may damage the ball guid s which would result in a tight or rough p rating worm.*

4) Remove the two worm connector ball guide clamp screws and lockwashers. Remove guide clamp. Using care not to lose any of the worm balls, carefully remove ball guide from the worm connector.

►*CAUTION: Balls used in worm conn ctor are a sel ct fit with each other. If any are lost or damaged, it is recommended that a complet s t (40) b install d.*

5) Turn worm connector over and carefully thread the remaining worm balls out of the worm connector by turning the worm in and out. Remove worm from connector.

►*CAUTION: If housing head has becom separated from gear housing, make sure th "O" ring is in position between housing h ad and gear housing.*

6) Secure housing head to gear housing by guiding tool C-3324 (Dummy Housing) over rails on worm connector until it is flush with gear housing. Install the three washers and screws, draw down evenly and tighten to 25-30 ft. lbs. torque.

7) Secure steering gear arm from stock or remove the one from vehicle. Install steering gear arm, lockwasher and nut. Tighten nut to 30-40 ft. lbs. torque. Install the 3/4" hose adapter fitting in the return outlet of the gear housing. Connect return hose (large diameter) C-3318 to the 3/4" adapter fitting. Connect small end of C-3211 hose to the 5/16" adapter (pressure) in gear housing. Install pressure gauge C-3309 in pressure side of pump. Connect the pressure hose C-3211 to fitting at the shut off valve. Connect the return hose C-3318 to reservoir and tighten all fittings. Thoroughly clean the outside of the reservoir and remove cover or filler cap.

8) To maintain oil in the reservoir to normal level while hydraulically centering the steering, add sufficient oil over and above the normal oil level of the reservoir to approximate the volume in the test hoses.

9) Open the shut off valve at the gauge and start engine. Allow engine to operate long enough for pump to circulate oil through steering gear assembly and test hoses.

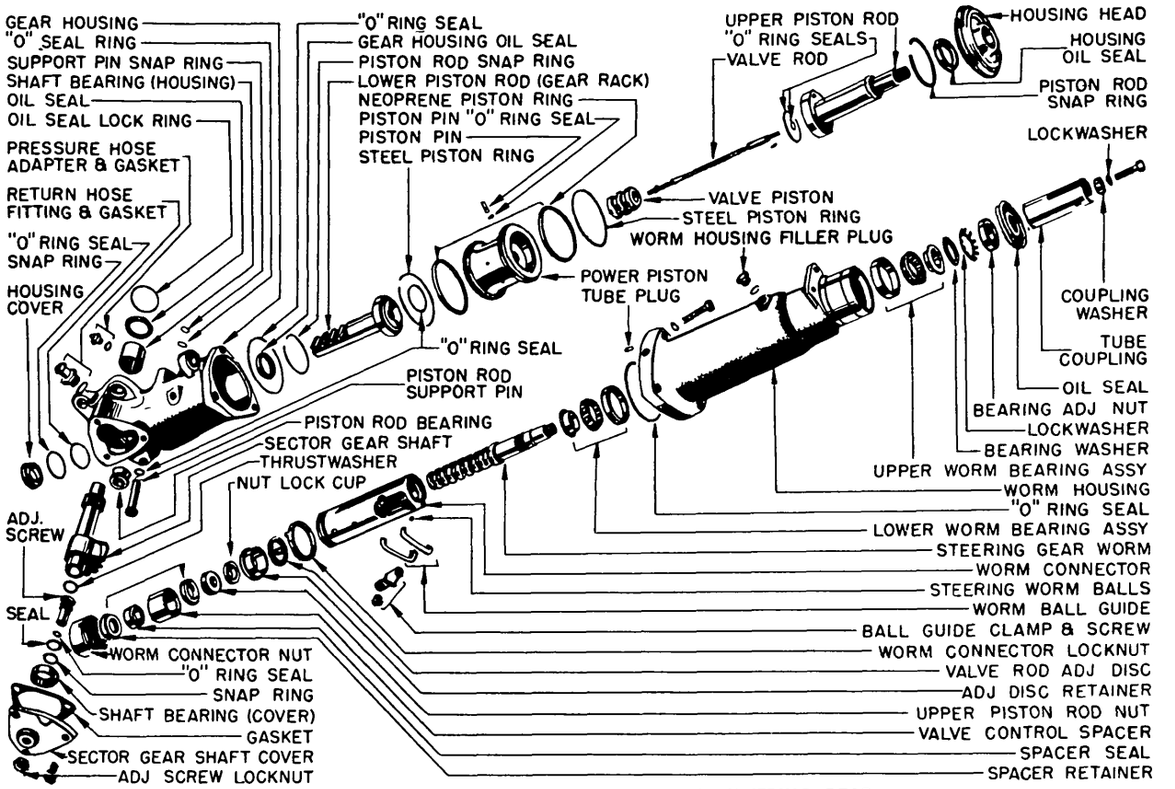
10) Place alignment cap and dial SP-2619, which is part of tool C-3325, over worm connector and lock in position by tigntening thumb screw Insert extension rod SP-2621 through alignment cap and over valve adjusting rod in bottom of worm connector. Tap extension rod lightly so that it is a tight fit on valve adjusting rodl Position adjusting handle SP-2620 on extension rod so there is approximately 1/16"

CONTINUED ON NEXT PAGE

"CO-AXIAL" (C ntinu d)

clearance between handle and alignment cap, then lock in place by tightening set screw in handle Adjust valve by turning handle until the pump pressure registered on the gauge is at a minimum.

►*CAUTION: Do not apply heavy pressure on the adjusting tool as valve rod may twist off in assembly.*



11) Carefully rotate valve adjusting handle SP-2620 to the right until the piston bottoms in the gear housing. Then, rotate valve adjusting handle to the left until the piston bottoms in the opposite direction. Repeat the rotation of the valve adjusting handle first to the right and then to the left until piston bottoms each time. This operation purges the air from the gear housing.

12) Check the oil level in the reservoir and refill to the required level.

13) With engine idling, close the shut off valve and check pump pressure. The gauge should read approximately 750 psi. **Op n shut off valve.**

Cent ring C ntr l Valv –Turn valve adjusting handle SP-2620 until the steering gear arm reaches approximately the center of its travel and minimum pressure is again noted *(CAUTION–Adjust the gear shaft into a backlash condition at center of gear travel. Make sure that extension rod and tool handle fit tight on the adjusting rod. Turn valve adjusting handle in one direction until the steering gear arm just starts to move. Note degree of valve adjusting handle on dial. Th n, without removing handle, turn it in the opposite direction until steering gear arm starts to move at the same rate of speed in the opposite direction and again note the degree of valve adjusting handle on dial. Next, turn valve adjusting handle to cent r of th degrees required to move arm in both directions. R check to make sure adjustment is corr ct).* Stop engine, remove valve adjusting handle, extension and alignment cap. *(CAUTION–Do not change position of valv adjusting rod when removing tool. Do not disconnect test hoses at this time).* Remove the three screws from tool C-3324 (Dummy Housing), and carefully slide tool from worm connector assembly.

R quir d R -Ass mbly Operations After Adjusting C ntr l Valv –Insert worm shaft into connector and visually align the **upp r** portion of the spiral grooves with the ball guide holes. Insert 30 balls into lower hole by tapping them gently (use rubber end of a lead pencil or similar object) while slightly oscillating the worm. *(NOTE–*When the 30 have been inserted, they should be visible in the other hole). Place the remaining balls (10) in either half of the worm connector ball guide. Grease end balls to help hold them in place and add other half of ball guide assembly. Insert assembly into holes until it seats on worm connector. Place ball guide clamp into position on ball guide and install the two lockwashers and screws. Tighten to 10-12 ft. lbs. torque. Check operation of worm making sure it is free to oscillate. Caution should be exercised not to bottom worm in the outward direction, otherwise damage to the ball return guide may result and cause a rough or tight operating

1954-55 CHRYSLER & DESOTO "CO-AXIAL" POWER STEERING GEAR

worm. Lubricate worm connector rails with Lubriplate. Lubricate housing head "O" ring with Lubriplate and install on housing head pilot opposite piston side. Drop inner bearing into housing and hold in place, rotate connector so ball guide is in downward position and pilot worm housing over rails on worm connector until flush with gear housing.

►*CAUTION: Worm housing cannot be installed if bearing is installed on worm shaft prior to installing housing.*

Install the three screws and belleville washers, draw down evenly and tighten to 25-30 ft. lbs. torque. Lubricate worm outer bearing roller with Lubriplate and install in bearing cup. Slide thrust washer over worm and against outer bearing race and follow with worm bearing nut lockwasher. Turn worm shaft out until lower race seats in bearing. Install worm housing bearing adjusting nut (tapered end first). Place tool C-3320 over worm shaft followed by tool C-3319. Then using tool C-3319, with a torque wrench, turn worm shaft in a clockwise direction to 20 ft. lbs. torque against inner bearing. While holding worm shaft at this point against inner bearing, use tool C-3320 with another torque wrench and tighten adjusting nut to 15 ft. lbs. torque. Rotate worm shaft several times to insure proper seating of bearings. Next, loosen adjusting nut and again using tool C-3319 with torque wrench, hold shaft at 5 ft. lbs. torque (clockwise direction) against inner bearing and retighten adjusting nut to **5 inch pounds torque.** Lock adjusting nut in position by bending tang of lockwasher to index with slot in the nut. (NOTE–Only one tang needed to lock adjusting nut).

►*CAUTION: Too loose adjustment will result in fre play before steering is accomplished. Too tight an adjustment will result in erratic steering and lack of returnability.*

Using driver C-3317, drive worm housing oil seal (lip of seal in) until it is seated against worm housing. Add 18 ounces of SAE-10W oil to the worm housing through worm bearing filler hole. Keep gear assembly in a level position to facilitate filling. Install worm housing filler plug and tighten to **50 inch pounds torque.**

►*CAUTION: It is very important that the worm housing be filled since there is no hydraulic connection between the worm and gear housings.*

CENTERING STEERING TUBE COUPLING & ADJUSTING BACKLASH BETWEEN GEAR SHAFT & RACK TEETH: With unit off car, turn worm shaft from one extreme of its travel to the other and count the number of turns; this should be approximately 3 3/4 turns.

CONTINUED ON NEXT PAGE

"CO-AXIAL" (Continued)

Then starting with the worm shaft setting at one end of travel, turn it back 1 7/8 turns (approximately center position). With steering gear centered as above, install the tube coupling with the slot in a vertical plane in the installed position of the gear assembly. **Do not install screw and washer at this time.** Then proceed as for adjustment of "Gear Shaft Only (Unit in Vehicle)" above noting the following

1) Slot in coupling, when installed, must be relative to the center of no backlash arc and not the overall travel (3 3/4 turns of the steering gear). If installed incorrectly, and the steering gear is installed in vehicle, the jacket and shroud assembly will have to be removed in order to correct.

2) When adjustment completed, stop engine and tighten adjusting screw locknut to 40 ft. lbs. torque. Install coupling screw and lockwasher and tighten to 15-20 ft. lbs. torque.

3) Disconnect C-3211 and C-3318 hoses and remove adapters from gear housing. Install pressure hose connector and gasket, tighten to 18-22 ft. lbs. torque. Install return hose connector and copper gasket, tighten to 25-30 ft. lbs. torque. Cap fittings to prevent loss of oil.

4) Remove steering gear arm (to permit installation of unit in vehicle).

5) Remove holding fixture C-3323.

6) Refer to "Required Re-Assembly Operations After Adjusting Control Valve" above.

1955 MODELS

GEARSHAFT ADJUSTMENT *(Early Cars–See Production Change & Adjustment Caution above)*–Check steering for being properly centered by turning the coupling in each direction from center Pitman arm backlash should become evident at equal distances in both directions when turning from center It may be necessary to reposition the coupling to obtain equal travel in both directions in which case it will be necessary to readjust pitman arm backlash *See "Installing Coupling at Center" (below)*

GEARSHAFT ADJUSTMENT: *(Later Cars–See Production Change & Adjustment Caution above)*–Center the steering tube coupling or steering wheel to the overall travel of the steering gear *With gear in center position* loosen adjustment screw in end of shaft opposite pitman arm until there is some backlash Slowly turn adjusting screw in until the backlash disappears **Turn the adjusting screw in ¼ of a turn and lock in position** *(CAUTION–Use a very light touch on steering wheel when checking for backlash)*

►*LATER TYPE GEARSHAFT INSTALLATION ON EARLY MODELS WITH FIRST TYPE GEARSHAFT* Later type gearshaft can be installed on early cars without changing the lower piston rod If new shaft is used, the later type adjustment must also be used

►*IDENTIFICATION OF EARLY CARS WITH LATER TYPE GEARSHAFT (Installed in field)* If difficulty is experienced in adjusting the gearshaft on early cars, the following check may be made to determine if later type gearshaft installed Center steering wheel and tighten adjusting screw until a small amount of backlash is felt, then turn coupling or wheel to either extreme limit If backlash increases, it is the early type gearshaft

Installing Coupling at Center: Install steering tube coupling with slot in coupling in the vertical plane There are no master serrations on either worm shaft or the coupling *A mark is scribed on the coupling which* must be set at 12 o'clock when the steering worm shaft is at center so that the steering tube master serration will be in position to allow for proper installation of steering wheel

MANUAL CONTROL VALVE NEUTRAL POSITION ADJUSTMENT (Power Steering Unit Removed): With unit secured in a vise or suitable fixture, connect test hoses to hydraulic pump on car and to steering assembly Remove oil reservoir cover Start engine and operate at idle Fill reservoir to level mark and allow system to warm up *(CAUTION–Oil level must be maintained above filter while hydraulically centering valve)* Insert manual control valve centering tool C-3445 (slotted end first) into worm shaft and engage slot in tool with tang on control valve operating rod (tool can be rotated by using a tap wrench) *If pitman arm moves to one extreme or the other and stays there, rotate tool in either direction until arm starts to move Slightly rotate tool in opposite direction until arm stops moving.* Install a 1 7/16" socket on a torque wrench and place on pitman arm retaining nut Rotate gear shaft in both directions from one extreme to the other The torque required should be the same in both directions Where torque is higher in one direction than in the opposite rotate the valve adjusting tool slightly in the opposite direction to the direction in which the pitman arm has the highest torque reading *(Change valve position in slight variations to prevent over adjusting).* When torque is the same in both directions, remove tool

MANUAL CONTROL VALVE NEUTRAL POSITION ADJUSTMENT (Power Steering Unit in Car): *(NOTE–The following procedure can be used when it is difficult to rotate the steering wheel in one direction but not in the other, or where the wheels turn of their own accord Before proceeding with the adjustment, make sure that unequal tire pressure is not the cause of steering wheel turning hard in one direction).* Remove all parts, as necessary to gain access to steering tube coupling Remove coupling retaining screw, lockwasher and plain washer from worn shaft Insert manual control valve centering tool C-3445, slotted end first into worm shaft and engage tool with tang on control valve operating rod *(NOTE–Two men are required to* center the valve) Move pitman arm through its travel from one direction to the other with a torque wrench and a 1 7/16" socket, observing the torque reading The torque should be the same in both directions Turn adjusting rod as required until an equal torque reading is obtained *(NOTE–Where gearshaft requires more* than 40 ft lbs to rotate it, or where torque is uneven at any point through the full shaft travel, check for cocked gear shaft cover, dirt in unit, or recirculating balls are defective or improperly installed)

PUMP DRIVE BELT ADJUSTMENT: Sufficiendy tight to prevent slipping.

HYDRAULIC PRESSURE TEST

Connect Gauge C-3309 in pressure line between pump and hose Refill reservoir to proper level Open valve on gauge, start engine, and run until power steering oil pump reaches operating temperature With engine at normal operating speed, turn shut-off valve on gauge to its closed position *(CAUTION–Do not keep valve closed more than a few seconds or accelerate engine with valve closed)* If pressure does not gradually increase to 700 lbs pressure (Chrysler & DeSoto), 600 lbs pressure (Dodge), 750-800 lbs pressure (Plymouth), it is possibly due to fan belt slipping, or flow control valve stuck in the open position or a broken drive coupling If the above pressures are indicated on the gauge, pump is in operating condition

►*TESTING NOTE*–If gauge not available, a fairly accurate way of making the test is as follows Start engine and turn the wheel to both extreme positions. If the high pressure hose flexes, the pump is in good condition. If hose does not flex, lack of pressure from pump is indicated. Shut off engine and check pump as indicated below.

PUMP CHECK: *Remove cover from reservoir start engine* and turn steering wheel If oil does not flow through filter a stuck flow control valve is indicated Shut off engine Remove high pressure hose at pump fitting and insert a ¼' blunt probe against valve plunger If plunger moves inward 3/16-1/4", plunger was stuck and will probably function properly next time Recheck pressure and if found to be below normal (see above), remove flow control valve and clean thoroughly If this does not correct the condition, remove and repair pump assembly If oil does not flow through reservoir filter in above test, check for broken filter or slipping fan belt Check shaft rotation by hand if coupling found to be broken If shaft turns freely install new couplings on both pump and generator shaft If pump shaft binds when turned by hand, replace both pump and couplings If armature shaft is damaged, replace necessary parts

TROUBLE SHOOTING

HARD STEERING IN BOTH DIRECTIONS: **1)** Leak in steering system, pump belt slipping or broken, fluid level low.

2) Steering gear linkage not lubricated, tire pressure too low, bind in steering column or gear, improper front end alignment.

3) Low pump pressure (see Hydraulic Pressure Test above) with particular attention to following Relief and flow control valve, rotors (not turning or worn), pump body or cover worn.

4) Loss of pressure in power unit (see Hydraulic Pressure Test above).

SMALLER TURNING RADIUS IN ONE DIRECTION: **1)** Wheel stops not adjusted properly.

HYDRAULIC LEAKS: **1)** Check for leaks at hose adapters, pump body, between gear and worm housings, and gear shaft oil seal.

HARD STEERING IN ONE DIRECTION ONLY: **1)** Tire pressure too low.

2) Control valve maladjusted.

3) Bind in steering column or gear, improper front end alignment.

CONTINUED ON NEXT PAGE

"CO-AXIAL" (Continued)

VEHICLE ATTEMPTS TO TURN UNLESS FORCE APPLIED TO HOLD STEERING WHEEL: 1) Tire pressure uneven.
2) Control valve maladjusted.

POOR RECOVERY ON TURNS: 1) Tire pressure too low, improper front end alignment.
2) Gear shaft adjustment too tight, worm bearing adjustment too tight.
3) Balls in worm connector binding, fit too tight.
4) Bind in steering column or gear, bind in steering knuckles.

NOISE IN CHUCK ASSEMBLY: Check belt adjustment. Check for vibrating condition set up by control shaft rod. Remove unit and install a new valve rod adjusting disc.

HISSING NOISE (NO LOAD): Caused by low oil pressure or improper operation of back pressure valve.

HISSING NOISE (RIGHT TURN ONLY): Caused by oil leaking past lower piston rod gear housing seal.

HISSING NOISE & LOSS OF OIL THROUGH UPPER HOUSING VENT (LEFT TURN ONLY): Caused by oil leaking past upper piston rod housing head oil seal.

CREAKING NOISE ON TURNS: Check for loose gear-to-frame mounting bolts. If noise persists after tightening gear-to-frame bolts, install a new equal tooth sector or gear shaft.

SNAPPING NOISE: Tighten gear-to-frame mounting bolts. Check coupling screw for tightness. Check lower piston rod bushing dowel pin for being too high. Check bushing for seating properly. Check lower piston rod for tight fit at piston.

CHUCKLE NOISE: Check as follows: Steering arm nut loose on gearshaft. Loose front wheel bearing. Gearshaft adjustment too loose. Excessive kingpin endplay. Steering tube coupling screw loose. Worm bearing preload adjustment too loose. Excessive worm shaft endplay.

WANDER (STEERING WHEEL FREEPLAY): Check steering wheel freeplay which should not exceed 5/8". If freeplay excessive (without moving steering linkage), check in same manner as for "Chuckle" above, and also check steering linkage and front wheel alignment.

POOR RETURNABILITY (BOTH DIRECTIONS): Check torque required to turn gearshaft from one extreme to the other with torque wrench on steering gear arm nut (linkage disconnected from steering arm). Torque should not exceed 40 ft. lbs., ± 10 lbs. If torque reading not excessive, check wheel alignment and steering linkage. If torque excessive, check steering column jacket bearing. Check gearshaft adjustment. Check worm shaft bearing preload. Check wormshaft for binding in connector.

POOR RETURNABILITY (ONE DIRECTION ONLY): Check tire pressure. Center control valve (see Adjustment). Check gearshaft adjustment.

UNEQUAL STEERING EFFORT: Check control valve adjustment. Check for upper piston rod movement in piston. Check worm shaft connector nut for tightness. Check control valve rod for looseness in valve. Check upper piston rod nut for looseness. Check upper piston rod for being scored at reaction seal retainer. If the above fails to correct unequal steering effort, replace all reaction parts.

UNABLE TO MAINTAIN CONTROL VALVE ADJUSTMENT: This may be caused by reaction spacer being too short or too long, or by burrs or out of squareness. Check valve control rod for looseness in disc, or control valve looseness on rod. Upper piston rod nut may be loose, or upper piston rod may be loose in piston.

LACK OF ASSIST (ONE DIRECTION): Check for damaged neoprene piston ring. Check for damaged or improperly seated housing head oil seal. Valve rod lower "O" ring may be damaged, or piston rod "O" rings may be damaged.

LACK OF ASSIST (BOTH DIRECTIONS): Check the following: Low tire pressure. Drive belts slipping. Low oil pressure.

LUBRICATION

Since there is no hydraulic connection between the worm and gear housing, the Power Steering has two separate fluid levels. Lubricate as follows:

Reservoir—Check every 1000 miles or every 30 days. Reservoir is mounted at rear of generator. Make sure top of reservoir is absolutely clean. Then, remove cover or filler cap and check oil level. Oil level should be 1/2" above filter element (if reservoir is tilted, oil level should be 1/2" above highest point of filter element). (NOTE—An oil level mark is stamped on the inside of the reservoir or on the dipstick on type using a filler cap). Replenish as necessary with SAE-10W engine oil. When temperatures are constantly below minus (-) 10° F., drain hydraulic system and refill with SAE-5W engine oil (see Draining and Refilling Hydraulic System below). When temperatures are consistently above minus (-) 10° F., drain the lighter lubricant which may have been added and replace with SAE-10W engine oil. Should the vehicle be operated at extremely high temperatures, it may be necessary to drain and replace the SAE-10W oil with SAE-30 oil for the time it is being operated in these extremely high temperatures. NOTE—When temperature is below minus (-) 10° F. run engine for at least three minutes before putting car in motion or turning steering wheel. Capacity is approximately 2 quarts.

Worm Housing—(*NOTE*—It is not necessary to change oil in worm housing due to temperature). Worm housing does not require periodic checks (unless leakage occurs). However, should the steering gear assembly be removed for any reason, it is recommended it be checked at that time. The oil should be level with the filler plug opening when the gear assembly is in an installed position. Replenish as necessary with SAE-10W engine oil.

DRAINING HYDRAULIC SYSTEM: *(CAUTION—Extreme care should be taken to prevent dirt from entering reservoir while cover or filler cap is removed. To prevent damage to filter element, do not insert sharp objects into reversoir. Do not disturb filter element as periodic changes of this unit are not required).* Disconnect high pressure (small) hose at the gear housing and jack up front end of car sufficiently to raise wheels off floor. Place hose in suitable container. While holding hose in container start engine and allow to idle, turn steering wheel from one extreme to the other until all fluid is forced from unit. *(CAUTION—Do not run engine above idle speed. As soon as fluid starts to show great quantities of air bubbles, stop engine).* Reconnect high pressure hose and refill.

REFILLING HYDRAULIC SYSTEM: Bleed steering gear as follows: Fill reservoir slightly higher than normal. Start engine and run for a short time to circulate oil through hoses. With engine running at idle speed, turn steering wheel back and forth several times from extreme right to left to bleed any remaining air out of system. Check oil level in reservoir. Add oil to reach level mark. Capacity is approximately 2 quarts.

REMOVAL & INSTALLATION

1954 MODELS

REMOVAL: Turn steering wheel to extreme left position to allow for removal of steering gear arm and drag link. Remove horn control ring ornament, cushion and spring. Disconnect horn wire and remove steering wheel nut and wheel. (NOTE—Horn control ring and contact plates will have to be removed if puller C-612 used to remove wheel. See below). Remove steering wheel column jacket bearing spring and spacer (cone shaped). Remove three shroud-to-toe board cover screws, then remove cover from the shroud. Remove accelerator and brake pedal pads and floor mat. Remove steering column jacket toe pad screws (6) and slide toe pad up on jacket assembly. Remove floor pan pedal opening cover screws, remove cover. Remove directional signal indicator, horn and selector lever indicator light wires. Disconnect pressure and return hose from steering gear housing and cap fittings.

Steering Wheel & Horn Button Removal (Using Puller C-612): Disconnect battery, center steering wheel in straight-ahead position. Press down on horn blowing ring ornament and turn counter-clockwise. Lift out ornament retaining spring and pad. Disconnect horn wire from terminal on travel plate and insulator assembly. Remove bushing, travel plate, horn blowing contact ring spring and triangular ground plate. Curl and push horn wire into steering gear tube to make room for steering wheel puller pilot. Remove steering wheel nut. Attach puller Tool C-612 and remove wheel.

▷*CAUTION: Fasten ends of hose above level of reservoir to prevent further loss of oil.*

Remove cotter pin and disconnect gearshift control rod from gearshift rod lever. Remove steering gear arm nut, then using tool C-143 with short puller screw SP-2623, remove steering gear arm and drag link. Remove access cover in left front fender shield and remove front lever steering gear assembly to bracket screw, washer and spacer (convex). Note position of wedge between bracket and gear housing. Remove front upper and rear steering gear assembly to bracket screws, washers and spacers (convex) through opening in toe board.

CONTINUED ON NEXT PAGE

"CO-AXIAL" (C ntinu d)

►*CAUTION: Do not lose spacers or wedge.*
Holding jacket and shroud assembly in position, remove the two steering column to instrument panel screws.

►*CAUTION: Steering column to instrument panel screw retaining plate and anti-squeak pad may fall from behind instrument panel when screws are removed.*
Lower jacket and shroud assembly, then remove insulator collar. Slightly push the steering gear column jacket and shroud assembly toward passenger side of vehicle (to permit gear shaft to clear frame bracket) and remove assembly through toe board opening. Place assembly on bench, loosen gear shift rod lever nut and slide lever and spacer (oilite) off gear shift rod. Loosen two nuts on the jacket clamp assembly and slide the jacket and shroud assembly from worm housing. (NOTE–Spring and spring seats (2) may fall from gear shift rod when jacket and shroud assembly is removed). Remove steering gear tube insulator pin, then remove tube and insulator from coupling.

INSTALLATION & ALIGNMENT: Center gear to center of no backlash arc (slot in coupling vertical). Place steering gear tube insulator on tube and position tube and insulator (master serration on steering wheel end of tube in "UP" position) in coupling. Install pin. The horn connector which is located on the jacket assembly is spring loaded. Because of this, the contact point will have to be raised to permit clearance with contact ring on steering tube when jacket and shroud assembly is installed. To accomplish this, bend one end of a piece of wire in the shape of a hook to raise contact point, then bend other end over shroud to hold it in raised position while being installed.

►*CAUTION: In some instances it will be necessary to remove lower half of shroud from jacket assembly and remove horn connector from jacket. Install jacket assembly over steering gear tube, then install horn connector on jacket and reassemble.*
Place gear shift rod spring seats in position in spring (flange portions of seats facing to inside of spring), slide spring and seats over gear shift rod. With horn contact held in raised position by piece of wire and holding spring and seats on gear shift rod, slide jacket and shroud assembly over steering gear tube, guiding gear shift rod into bushing on gear housing. Tighten the two nuts on the jacket clamp assembly and remove piece of wire which was used for holding the horn contact point. Install steering gear assembly through toe board opening pushing column jacket and shroud assembly slightly toward passenger side of vehicle to permit gear shaft to clear frame bracket. Install front upper and rear steering gear housing to bracket spacers (convex), screws and washers through opening in floor pan. Tighten (snugly), then back each one off one turn. Position insulator collar on upper shroud and align the jacket and shroud assembly to instrument panel. Install the two screws, tighten securely. Tighten front upper and rear steering gear housing to bracket screws to 70 ft. lbs. torque (ones that were loosened one turn). Install front lower steering gear housing to bracket spacer (convex), washer and screw **but do not tighten.** Tap wedge into position (over front lower gear to bracket screw) and between bracket and gear housing.

►*CAUTION: Make definitely sure wedge is positioned properly. Tap wedge lightly but do not drive.*
With wedge in position, tighten front lower steering gear housing to bracket screw to 70 ft. lbs. torque. Replace access cover in left front fender shield. Install steering gear arm and drag link, tighten steering gear arm nut to 100-120 ft. lbs. torque. Connect direction signal indicator, horn and selector lever indicator light wires. Install steering column jacket bearing spacer (cone shaped) and spring. Install steering wheel, tighten nut securely (install horn contact plates and control ring, if removed) and connect horn wire. Install horn control spring, cushion and ornament. Check clearance between steering wheel and direction signal housing. If clearance is more or less than 1/8" loosen the two column jacket to instrument panel screws slightly, then, loosen the two nuts on the jacket clamp assembly at top of worm housing and slide steering column jacket upward or downward to allow for proper clearance. Retighten jacket clamp assembly nuts and column jacket to instrument panel screws. Slide gear shift rod lever spacer (oilite) and lever on rod. Position selector lever in low or reverse, then holding the gear shift rod lever and spacer flush against gear housing, tighten nut.

►*CAUTION: Make definitely sure the selector lever remains in the low or reverse position while tightening nut. This procedure necessary to obtain the proper selector lever gate clearances. Check operation by shifting selector lever to all positions.*
Connect gear shift control rod to lever and install cotter pin. Remove the protective caps from fittings in gear housing and connect the pressure and return hoses. Remove reservoir cover or filler cap and fill reservoir to proper level. Start engine and turn steering wheel from one extreme of its travel to the other several times to purge air from system and note operation of steering. If steering seems to operate properly, install the floor pan pedal opening cover and tighten screws securely. Slide the steering column jacket toe pad down into position and install screws (6). Install floor mat, accelerator and brake pedal pads. Place cover on shroud and install screws (3). Recheck oil in reservoir and fill to proper level. Place selector lever pointer in neutral (N) position. Disconnect gear shift control rod at bellcrank located on transmission. Make sure manual control lever (at transmission) is in neutral (N) position (second detent position from rear of vehicle). With selector lever pointer still in neutral (N) position, adjust the gear shift control rod to the required length for a free fit in the lever of the bellcrank, then re-install rod. Operate selector lever through all indicator positions. Road test vehicle.

1955 MODELS

REMOVAL: Remove horn ring and ornament from steering wheel. Disconnect horn wire and remove horn ring. Remove steering wheel with puller C-612, and remove signal lever and plate. Loosen steering column to instrument panel bracket. Loosen steering column jacket clamp screws and raise front of car. Disengage drag link from pitman arm and pull pitman arm with Tool C-3402. Loosen three gear housing to frame attaching bolts. Remove floor mat retaining plate and rubber dust pad. Disconnect pressure and return hoses and drain gear assembly by slowly rotating steering wheel until all oil is expelled from unit. Fasten disconnected ends of hoses above oil level in reservoir to prevent loss of oil and cap hose ends to prevent dirt entering. Remove gear housing to frame bolts and alignment wedge and remove gear assembly from lower side of car.

Steering Wheel & Horn Button Removal (Using Puller C-612): *See 1954 Removal & Installation.*

INSTALLATION & ALIGNMENT: Install steering gear assembly from under the car and up through the dash panel into the jacket. Install housing to frame attaching bolts, flat washers, swivel washers and nuts, but do not tighten (swivel washers permit alignment to dash). Slide steering column jacket down over worm housing. Install turn signal lever, being sure column jacket does not restrict lever. Tighten jacket to steering gear housing clamp. Connect turn signal wires. Install steering column to instrument panel bracket and install steering wheel. If clearance between steering column jacket and steering wheel is less than 1/8", adjust steering column jacket to provide proper clearance. Install dust pads and retaining plates. Tighten front upper and lower gear housing to frame attaching bolts to 20 ft. lbs. Install wedge over rear bolt between housing and frame, so that tapered surfaces match, tapping it lightly in place. Tighten three attaching bolts to 70 ft. lbs. Install horn ring and horn wire in steering wheel and install horn ring ornament. Connect hoses from steering gear to hydraulic pump.

STEERING GEAR OVERHAUL

►*CAUTION:* Cleanliness in executing all overhaul procedures cannot be over-emphasized. Unit should be thoroughly cleaned in a suitable solvent when removed from vehicle. When disassembling, each part should be placed in the solvent, washed, then dried with compressed air. Careful handling of parts is necessary to avoid occurrence of nicks and burrs. Crocus cloth may be used to remove small nicks and burrs provided it is used carefully. When used on valve spool, use extreme care not to round off sharp edge portion. (NOTE–Sharp edge portion helps prevent dirt and foreign matter from getting between the valve and bore, thus reducing possibilities of sticking). Remove and discard all "O" ring seals, and seals, using new ones lubricated with Lubriplate when reassembling.

DISASSEMBLY & INSPECTION: Proceed as follows:
Removing Worm Gear using: 1) Drain lower portion of steering gear through pressure and

CONTINUED ON NEXT PAGE

"CO-AXIAL" (C ntinued)

return connections, by turning steering tube coupling from one extreme of travel to the other. Using a 3/16" allen wrench, remove worm housing filler plug and drain worm (upper) housing.
2) Attach holding fixture C-3323 to unit and place in vise.
3) Remove tube coupling screw, lockwasher, and washer from center of coupling. Using tool C-3392, remove coupling from worm shaft. (NOTE—Tool C-3112 may also be used to remove coupling. However, to accomplish this, it will be necessary to cut one adapter plate SP-1409 in half and using these two parts instead of the two plates).
4) Using extreme care and a screwdriver, remove worm housing oil seal from housing and worm shaft.
5) Unlock bearing adjusting nut by bending tang of lockwasher. (NOTE—Only one tang locks nut in position). Place tool C-3320 over worm shaft followed by C-3319. Holding the worm stationary remove worm bearing adjusting nut, lockwasher, and thrust washer (NOTE—Worm bearing adjusting nut tapered on one side).
6) Remove worm outer bearing race and bearing roller from worm. Inspect bearing roller for wear or pitting.
7) Remove three worm to gear housing screws and belleville washers (Note installed position of washers on screws. Concave side of washers fit against housing). Remove worm housing. (NOTE—It may be necessary to tap housing lightly due to interference of "O" ring seal between housing head and housing.
8) Remove inner bearing race from worm shaft and inspect for wear or pits.
9) Remove lower bearing. roller from housing. Inspect bearing roller and the upper and lower bearing cups in housing. **Do not r move bearing cups unless insp ction r v als it is necessary to do so.** To remove upper and lower bearing cups use tool C-3322.

R moval f Worm Connect r: 1) Remove housing head "O" ring and discard (Use new rings when assembling). Unlock worm connector nut lock and slide lock back sufficiently to loosen worm connector nut.
2) With tool C-3321 attached to worm connector, remove connector nut using tool C-3326 (NOTE—It may be necessary to rotate steering gear shaft to raise worm connector and permit installation of tool C-3326).
3) Slide worm connector assembly from valve control spacer.

Disass mbly of W rm C nnector—*(CAUTION—Do not bottom worm shaft in the outward direction upon disassembly or assembly. Bottoming the worm shaft may damage the ball guides and cause a tight and rough operating worm).*
1) Remove the two worm connector ball guide clamp screws and lockwashers. Remove guide clamp.
2) Using care not to lose any of the worm balls, carefully remove the ball guide from the worm connector. *CAUTION—Worm balls are a select fit with each other. If any of them are damaged and require replacing, it is recommended that a complete set (40) be installed.*
3) Turn worm connector over and carefully thread the remaining worm balls out of the worm connector by turning worm in and out. Count the worm balls which were removed so that the same number can be installed. There should be (40).
4) Remove worm from connector, slide connector nut lock from connector.
5) Inspect guide rails on connector for nicks and burrs.

Removal of Piston & Rods from Gear Housing: 1) Remove pressure and return hose adapters and copper gaskets.
2) Remove steering gear shaft oil seal lock ring (circular section), then, using tool C-3350, remove steering gear shaft oil seal.
3) Remove lock nut from shaft adjusting screw.
4) Remove three cover screws, belleville washers, and neoprene seals.
5) Remove steering gear shaft cover from housing by turning adjusting screw in. Remove cover gasket and discard (use new gasket when reassembling).
6) Using steering arm (if necessary) align steering gear shaft with cover opening in housing. Remove steering gear shaft assembly from gear housing by using a fiber hammer and tapping lightly.
7) Using tool C-3229, remove adjusting screw retaining snap ring. Remove adjusting screw, thrust washer and washer from steering gear shaft. Remove adjusting screw "O" ring.
8) Inspect needle bearings in cover for broken needles and inspect bearing surface on shaft for scoring or pitting. *CAUTION—Do not remove bearing from cover as bearing and cover are serviced as an assembly. Inspect condition of teeth on shaft.*
9) Using C-760 pliers remove gear housing cover snap ring (tapered) at bottom of housing, remove housing cover. Remove "O" ring from housing and discard (use new ring on reassembly).
10) Place a suitable container under the assembly (to catch trapped oil), then slide piston assembly and rods from gear housing. *CAUTION—Use extreme care in handling so as not to damage the sealing surfaces on housing head.*

Disassembly of Piston & Rods— 1) Remove valve rod adjusting disc from valve rod, slide valve rod adjusting disc retainer from upper piston rod, remove upper piston rod nut lock cap.
2) Using tool C-3328, remove upper piston rod nut. *CAUTION—Support upper piston rod on block of wood to help prevent damaging housing head when removing nut. Assembly may also be supported by wrapping several layers of masking tape around the rack teeth and sealing surfaces of lower piston rod and clamping it in a vise equipped with protective jaws.*
3) Slide valve control spacer, seal assembly, upper and lower valve control spacer seal retainers from upper piston rod. Remove spacer retainers from spacer, slide seal assembly from valve control spacer.
4) Remove worm connector nut from upper piston rod, slide housing head off upper piston rod. Remove housing head "O" ring and discard (use new ring on reassembly).
5) Using suitable drift, remove upper piston rod seal (lip type) from housing head.
6) Remove two backup (steel) and "D" type (neoprene) piston rings from piston.
7) Using C-760 pliers, remove lower piston rod snap ring and slide lower piston rod from piston.
8) Using care not to bend valve adjusting rod, slide valve assembly from piston assembly.
9) Using a 1/4" punch, drive piston pin into upper piston rod, then using C-760 pliers, remove upper piston rod snap ring. **Note position and constructi n of snap ring.**
10) Remove upper piston rod from piston. Using a wire hook, remove piston pin and "O" ring from piston rod, discard "O" ring (use new ring on reassembly). Make sure oil passage is open. Inspect sealing surface on piston rod for scoring. Remove the two valve rod "O" rings (one in each end of upper piston rod) remove upper piston rod "O" ring (discard rings, use new rings on reassembly).
11) Remove lower piston rod "O" ring (discard and use new ring on reassembly). Inspect rack teeth and sealing surfaces on lower piston rod. Make sure oil return hole is open.
12) Inspect piston for nicks and burrs. Make sure all oil passages are open and free of dirt.

Removal of Relief Valve Assembly: Thread a ¼"-28 bolt into threads provided in plug. Clamp bolt in vise and pull on lower piston rod to remove plug. If end plug is seized in rod, tap on retaining flange at lower end of piston with a fibre hammer. Inspect piston for nicks and burrs. Make sure all passages are open and free from dirt.

Disassembly of Steering Gear Housing: 1) Using C-3128 pliers, remove piston rod bearing support pin snap ring. Slide bearing support pin out of gear housing and remove roller support assembly. Inspect roller and needle bearings. Inspect bearing support pin for wear or scoring. Remove two bearing support pin "O" rings located in each side of gear housing and discard (use new rings on reassembly).

2) Inspect steering gear shaft needle bearing in gear housing for broken or rough needles. **Do not remov bearing unless inspection reveals it is necessary to do so.**

3) Using driver C-3333, drive steering gear housing shaft needle bearing from inside gear housing. Remove lower piston rod seal (lip type) from housing.

REASSEMBLY & ADJUSTMENT:-Proceed as follows:

Steering Gear Housing: 1) Remove garter spring from a **new** piston rod seal (to prevent being damaged by tool when installing) and position seal over driver C-3331 (position seal so lip will be facing up or to inside of cylinder when installed). Insert seal aligning pilot of tool in end of driver and drive lower piston rod seal into position in gear housing. *CAUTION—Replace garter spring in piston rod seal.*

2) Using driver C-3333, install housing shaft needle bearing assembly into gear housing until driver marking on driver is even with side of housing. *CAUTION—Always drive on letter side of b aring, otherwis damage to bearing may result.*

CONTINUED ON NEXT PAGE

"CO-AXIAL" (C ntinued)

3) Lubricate the two **new** piston rod bearing support pin "O" rings with Lubriplate and install into gear housing at outer edge of bearing support pin holes. Make sure they are properly seated in housing.

4) Start piston rod bearing support pin through hole in cover side of housing. Place roller support assembly into position in housing and push support pin through roller assembly until it protrudes sufficiently on opposite side of housing to install snap ring. Using C-3128 pliers, install snap ring, making sure it is properly seated.

Piston & Rods 1) Insert relief valve spring followed by plunger into valve body and insert assembly (milled end first) into lower piston rod. Press end plug into lower piston sufficiently to seat against relief valve body *(NOTE*–A suitable adapter will be requiredto press end plug into place. Otherwise, damage to rod will result. If plug is not pressed in far enough to properly seat against the valve body, it will produce a rattling or clattering sound when hydraulic pressure is applied. If the plug is pressed in too tightly, it will cause relief valve ports in valve body to collapse, restricting the plunger and creating high back pressure, resulting in lack of steering assistance). Lubricate the two **new** valve rod "O" rings with Lubriplate and install one in each end of piston rod. Make sure the rings are seated properly.

2) Lubricate the two **new** large "O" rings with Lubriplate and install one on each upper and lower piston rod. Make sure rings seat properly in ring grooves.

3) Install lower piston rod (with rack) into end of piston assembly opposite piston pin hole and using C-760 pliers, install snap ring. *CAUTION–When installing snap ring, minimum gap opening of 25/64" is specified. Care should be exercised to locate the gap at the middle port of the five ports without obstructing the middle port or adjacent ports with snap ring ends. Make sure snap ring is seated properly.*

4) Lubricate valve assembly with Lubriplate and slide into piston assembly. Using care not to damage "O" rings, slide upper piston rod over valve rod, aligning piston pin hole in the piston assembly with the hole in the upper piston rod.

5) Lubricate **new** piston pin "O" ring with Lubriplate and install on piston pin. With piston pin holes aligned in both the piston and upper piston rod, position piston pin (tapered end first) in piston. Using a 1/4" punch and hammer, tap lightly until piston pin is flush with bottom of piston pin groove. Using C-760 pliers, install upper piston rod snap ring. S *CAUTION under 3) above.*

6) Remove garter spring from a n w upper piston rod seal (to prevent being damaged when installing seal) and position seal on driver C-3331 (lip of seal facing tool). Insert seal aligning pilot of tool in end of driver. Drive upper piston rod seal (lip of seal out) into position in housing head. Replace garter spring and lubricate seal with Lubriplate. Install housing head assembly (sealing lip first) onto upper piston rod. *CAUTION– Use extreme care to protect sealing surfaces on housing head.*

7) Slide connector nut onto upper piston rod with open threaded end away from piston.

8) Lubricate the valve control spacer seal (new) with Lubriplate and install in center of valve control spacer. *CAUTION–Should it be necessary to replace the valve control spacer or upper piston rod for any reason, always select a spacer to match. The length of the valve control spacer selected, must be identical to the distance between the seat of the valve control spacer seal retainer and the seated upper piston rod nut.*

9) Slide one of the valve control spacer retainers (large diameter first) on upper piston rod. Lubricate with Lubriplate. Place tool C-3329 over threaded end of upper piston rod. Lubricate the valve control spacer retainer with Lubriplate and place into position (small diameter first) so it nests in valve control spacer. Slide spacer, seal and retainer over tool C-3329 and into position on piston rod, remove tool.

10) Install upper piston rod nut and using tool C-3328, tighten securely (25-30 ft. lbs. torque). Lock in place using piston rod nut lock by tapping outer diameter of lock into nut recess.

11) Slide valve rod adjusting disc retainer (largest diameter first) over end of upper piston rod. Thread valve rod disc (extended lock thread section being outward) onto valve rod until approximately three threads show (for aid in later adjustment).

12) Place lock ring on worm connector (tang of ring toward threaded end). Slide worm connector (less ball bearings and worm shaft) over valve control spacer, then screw worm connector nut onto connector. Hold worm connector with tool C-3321, then using tool C-3326, tighten nut. Stake ring with punch.

13) Lubricate the two "D" type (neoprene) piston rings with Lubriplate and install on piston. To aid in installation of rings, first slide rings over ring lands and to center of piston with lips facing away from each other. Next, slide rings into position in ring lands. Install backup (steel) rings one on each end of the piston, in extreme position from the center of the piston.

Installati n f Pist n & R d Ass mbly int Gear H using: 1) Lubricate lower piston rod, teeth of rack and tool C-3391 with Lubriplate, then position tool in teeth of rack.

2) Place ring compressing tool C-3344 on gear housing. Position piston and rod assembly so teeth on rack are 180° from roller support assembly and install into gear housing. *CAUTION–Us extrem care when performing this operation so as not to damag gear housing oil seal or piston rings. Do not us screwdriver to compress piston rings. To further aid in installation, piston and cylinder may be lubricated with Lubriplate. If rack is not posirion d properly when it is installed, it may be correct d by rotating the lower piston rod with a scr wdriver through op ning in end of gear housing.* Remove ring compressing tool C-3344, and tool C-3391 from teeth of rack through opening in gear housing.

3) Lubricate large **new** "O" ring with Lubriplate and install on the side of housing head which faces piston assembly.

4) Carefully slide tool C-3324 (dummy housing) over worm connector and secure housing head to gear housing, tighten the three screws to 25-30 ft. lbs torque.

5) Install thrust washer on gear shaft adjusting screw and position tool C-3401 over thread of screw. Lubricate adjusting screw "O" ring with Lubriplate and slide over tool and into position on adjusting screw. Remove tool and insert adjusting screw thrust washer into gear end of steering gear shaft. Insert adjusting screw assembly into gear shaft and lock into position by inserting internal snap ring. Use C-3229 pliers and make sure snap ring is properly seated. Screw shaft adjusting screw with gear attached into the gear shaft cover assembly as far as possible.

6) Center the second tooth of the rack over center line of piston rod bearing support pin.

7) Lubricate a **new** gear shaft cover gasket with Lubriplate (to help hold it in place) and position it on cover of housing.

8) Center the center line of the middle tooth on gear shaft with second tooth **spac** from end of rack. Insert gear shaft assembly with cover attached into gear housing, tap lightly into position. Place belleville washers and new seals on screws and secure cover to gear housing. Draw down evenly and tighten to 25-30 ft. lbs. torque.

9) Lubricate **new** gear housing cover "O" ring with Lubriplate and install on housing cover. Push assembly (seal end first) into housing and install snap ring.

10) Before attempting to install a n w seal, thoroughly clean sealing surface on the gear shaft and counterbore of steering gear housing. Lubricate a **new** steering gear shaft oil seal with Lubriplate and place (lip of seal down) on a piece of clean paper. **Carefully** install tapered end of sleeve (part of tool C-3350) in seal and slide seal back approximately 1/4" on

CONTINUED ON NEXT PAGE

"CO-AXIAL" (Continued)

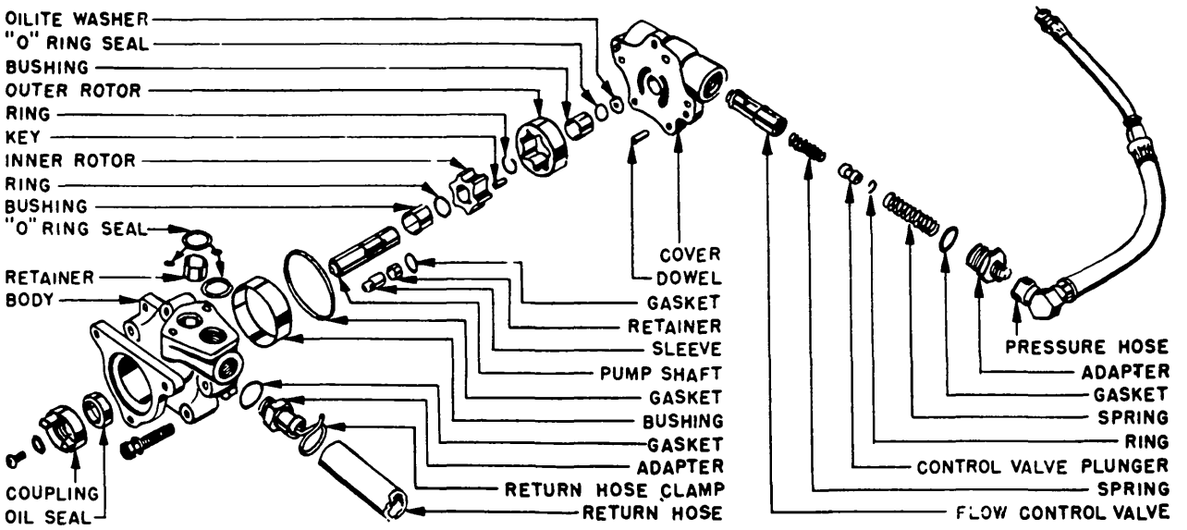
sleeve. Install this assembly (lip of seal toward housing) over steering gear shaft until seal contacts counterbore in housing. Push seal into position by installing adapter over sleeve, and installing coupling nut on shaft threads until shoulder of adapter contacts housing. Remove nut and adapter. Wrap a new piece of friction tape around sleeve to provide a firm grip and with a turning motion, remove sleeve from seal and gear shaft. Seal is then positioned properly. Install oil seal lock ring (circular section) and make sure it is properly seated. Install gear shaft adjusting screw lock nut, but do not tighten.

11) Secure steering gear arm from stock or remove one from vehicle. Install steering gear arm, lockwasher and nut, and tighten nut from 30-40 ft. lbs. torque (low torque reading for checking purposes only). Work steering arm back and forth forcing piston to its full length of travel. Adjust gear, if necessary, into a backlash position, then tighten lock nut.

CAUTION–This adjustment necessary before hydraulically centering gear assembly and is not to be considered a final adjustment.

12) Proceed as indicated under steps **7)** through **13)**, Centering Control Valve, and Required Re-Assembly Operations After Adjusting Control Valve, outlined under "Control Valve" in ADJUSTMENT section above.

13) For final gear adjustment proceed as outlined under "Centering Steering Tube Coupling & Adjusting Backlash Between Gear Shaft & Rack Teeth" in ADJUSTMENT section above.



HYDRAULIC PUMP

►*PUMP COUPLING NOTE:* Two different types of pump drive coupling have been used and special Pump and Generator must be used with each type coupling (special shaft used with each coupling).

1) Rubber Insulated Coupling–Oilite coupling flanges are pressed on generator and pump shafts and retained by special "thread locking" type capscrew and plain washer (lockwashers should not be used with these screws). A rubber insulator and insulator sleeve are installed between the coupling flanges to transmit the drive.

2) Metal Tongue Coupling–Tongue-and-slot type metal coupling. Coupling members are retained on shaft ends by a retaining ring and slide off after ring removed.

HYDRAULIC PUMP REMOVAL: Disconnect the two hoses from pump reservoir assembly and catch oil from pump in a drain pan. Tie the loose ends of hoses out of the way above steering gear assembly to prevent loss of oil. Cover the ends of both hoses. Remove the three pump-to-generator screws and remove pump (*CAUTION*–do not lose coupling insulator and sleeve on pumps with rubber coupling).

HYDRAULIC PUMP (SINGLE ROTOR TYPE)

Removal of Reservoir From Pump:

1) Remove cover assembly from reservoir, lift out filter element and drain oil from reservoir.

2) Install the small tapered plug Tool C-3117 and the large tapered plug Tool C-3118, into the two holes that permit passage of oil to pump (this will prevent dirt entering pump).

3) Remove the four reservoir-to-pump attaching screws and lift reservoir from pump, being sure not to lose one large rubber "O" ring and five small rubber "O" rings which are used as gaskets between pump and reservoir.

OVERHAUL OF PUMP: *CAUTION*–Cleanliness is extremely important when working on hydraulic pump. Pump should be thoroughly cleaned before disassembling, work bench should be covered with clean paper, and all parts should be kept in clean kerosene until reassembled to protect them from dirt and corrosion.

Disassembly ("Single Rotor" type): Remove coupling lock screw, then remove coupling. Install pump in vise with protective copper jaws. Remove five body-to-cover attaching bolts, then remove cover. Remove shaft and rotor assembly, then "O" ring seal and "oilite" thrust washer in bottom of pump shaft hole.

Bushing & Seal Replacement–*NOTE*–New seal should always be installed whenever bushing replaced. Replace bushing and seals as follows:

Pump Cover Shaft Bushing–Place pump body in vise with protective copper jaws, install Tool C-3185, tap threads into bushing with outer section of tool, using an open end or adjustable wrench. After tool threaded into bushing sufficiently, screw T handle section of tool into hole until tool bottoms in cover, remove bushing. To install, drift bushing into place with Tool C-3233.

Pump Body Shaft Bushing–Place pump body in vise with protective copper jaws, mount pump cover to pump cover to pump body, install attaching bolts. Install Tool C-3185 in cover bushing hole, thread tool into housing bushing, remove bushing and seal. To install, mount bushing to Tool C-3235 and drift bushing into place.

Outer Rotor Babbitt Bushing–Remove pump cover from pump body. Thread Tool C-3214 into pump body using adapter Tool C-3234, remove bushing. To install, drift bushing into place with Tool C-3251.

Pump Shaft Oil Seal Replacement–With pump body securely clamped in vise with protective copper jaws, mount seal to Tool C-3230, drive seal into place.

Cleaning & Inspection: Clean all parts thoroughly in solvent and blow dry with compressed air. Wash bearings in clean kerosene and dry by blowing air through bearing (*CAUTION*–do not spin bearing with air). Inspect bearings for wear or roughness and replace if they do not rotate freely. Inspect babbitt rings in pump body for wear or scoring. Inspect rotors and pump shaft for wear, scoring, or burrs (remove burrs with a fine stone or crocus cloth). Check end clearance of rotors by installing them in pump body and using a feeler gauge to measure clearance from rotor to straightedge placed on face of body. End clearance limits are .001-.0017". Check valve plunger.

CONTINUED ON NEXT PAGE

"CO-AXIAL" (C ntinued)

►*NOTE:* If rotors badly scored, or worn beyond limits given above, install complete new pump assembly.

R assembly ("Single Rotor" type): Use NEW "O" ring seals and gaskets. Lubricate all parts with clean SAE 10W engine oil, coat "O" ring seals with Lubriplate. Assemble pump as follows: Install flow divider valve (ported end first) into pump body. Insert small spring plunger and ring, using Tool C-3229. Install large spring, gasket and adapter. Tighten adapter to 45-50 ft. lbs. torque. Install shaft protector thimble Tool C-3228 in pump body until tool bottoms, install rotor shaft assembly, using care not to damage babbitt bushings when installing rotor. Position "O" ring seal in body. Place cover in position, installing attaching bolts and washers. Tighten bolts to not more than 17 ft. lbs. Install coupling flange on pump shaft, then special lock screw and washer. Hold coupling with Tool C-3227 and tighten to 10-12 ft. lbs. torque.

Installati n f Res rv ir n Pump: Install one large circular section "O" ring, and five (5) small "O" rings which are used as gaskets between reservoir and pump. Install small tapered plug, Tool C-3117 and large tapered plug, Tool C-3118, into the two passage holes in bottom of reservoir. Insert the two pilots, Tool C-3116, into matching screw holes of reservoir and pump and install reservoir to pump. Install the four attaching screws and tighten to 7-12 ft. lbs. torque.

HYDRAULIC PUMP INSTALLATION:

►*PUMP DRIVE COUPLING CAUTION:* Make certain that pump and generator have same type drive coupling. Couplings are not interchangeable and SAME TYPE PUMP AND GENERATOR MUST BE USED TOGETHER. When installing pump with rubber type coupling, make certain that rubber insulator and sleeve installed in generator drive flange.

1) Attach pump and reservoir assembly to generator, using care to index pump shaft tongue into groove of generator coupling. Tighten three pump-to-generator mounting screws to 12-17 ft. lbs. torque.

2) Attach the two hoses, using 3/8-5/8 of a turn after initial finger tightening. The constant section hose is the return line and connects to the reservoir fitting. The dual diameter hose is the pressure line and connects to the pump body fitting. If the hose connectors are ever removed, they should be tightened to 25-30 ft. lbs. torque.

3) Clean out reservoir with lint free, clean cloth before removing tapered plugs, Tools C-3117 & 3118. Install filter element in reservoir, and fill with SAE 10-W engine oil to 1½" below gasket seat. See *BLEEDING* above.

4) AFTER bleeding of the system completed and reservoir refilled to correct level, install reservoir cover and gasket and tighten cover bolt to 5-8 ft. lbs.

NOTE–If relief valve assembly cap removed, tighten to 5-8 ft. lbs. torque.

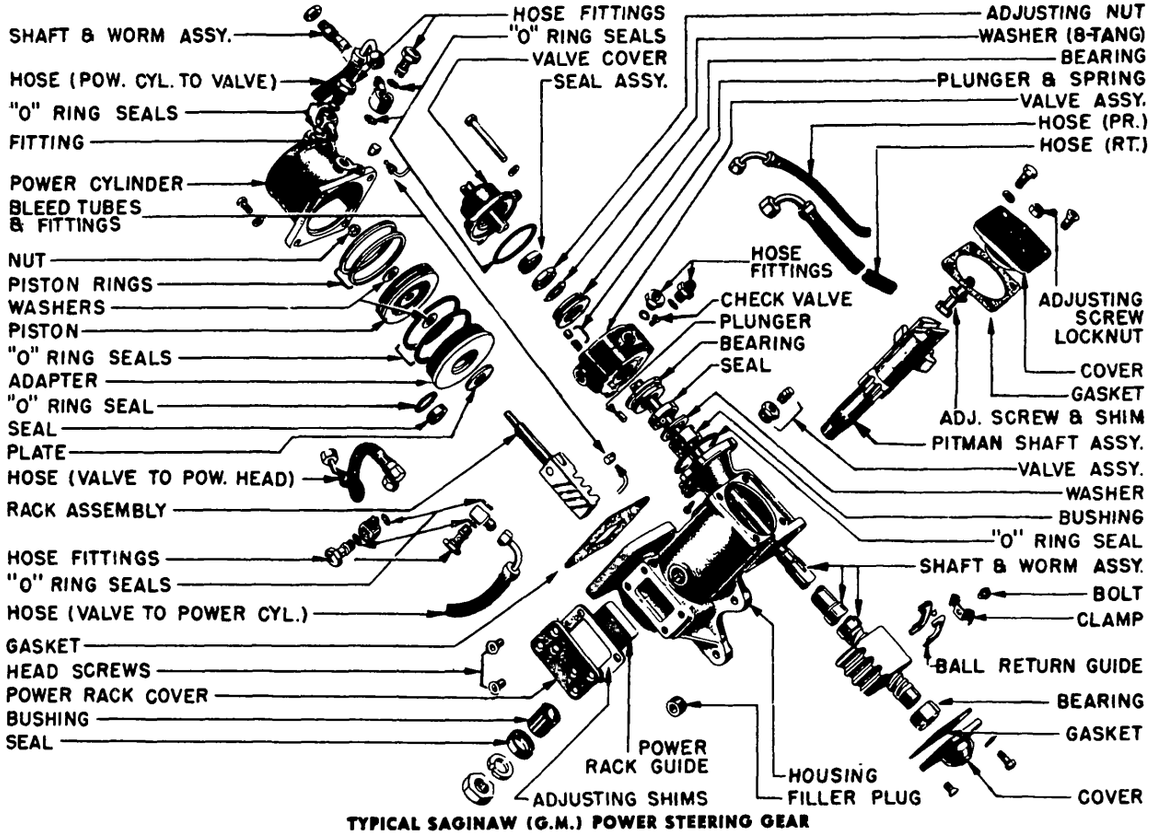
►CHANGES, CAUTIONS, CORRECTIONS



►***1952-53 BUICK STEERING SHAFT BEARING CAUTION:*** The 1952 bearing, Part No. 5663863, MUST NOT be used on 1953 steering gears. Use of this bearing may result in rattles and slight shaft looseness. ***Use 1953 bearing, No. 5664839, on 1953 gears.***

►***1953 CADILLAC "CHATTER" CORRECTION:*** To eliminate "chatter" requires modified worm thrust bearing adjustment. Replace old locknut with stake type nut, Part No. 5664762, **and do not use tanged washer.** ***Nut must spin on threads freely with no binding.*** Tighten staking nut to 10 ft. lbs., loosen nut and retighten to exactly 30 in. lbs. Check pull at steering wheel rim required to rotate wheel in **off-center** range and adjust as required for pull of ½-1 lb. Check to see that nut has not moved, then stake securely into keyway with rounded drift punch. After reassembly, recheck off-center drag. There may be an increase of ⅛-¼ lb. due to seal.

►***1952 CADILLAC STEERING GEAR DRAG LINK INTERFERENCE CORRECTION:*** If steering linkage contacts left exhaust pipe or engine oil pan in extreme turn positions (will be noted as vibration with wheels turned against stops), determine point of contact and correct as follows:

Interference between Drag Link & Left Exhaust Pipe—Turn wheels to extreme left turn position, mark point on exhaust pipe where drag link contact occurs. Cut away asbestos covering on exhaust pipe in this area for additional clearance. If interference still continues, make a flat dent in the exhaust pipe approximately 1¼" in diameter at this point. ***(CAUTION***—do not dent pipe so much as to interfere with flow of exhaust gases).

Interference with Oil Pan—If drag link contacts oil pan, correct as follows:
(1) Check and correct drag link height. ***See Steering Gear Adjustment (below).***

TYPICAL SAGINAW (G.M.) POWER STEERING GEAR

(2) If step (1) does not correct interference, loosen all three engine supports and shift engine to rear as far as possible. ***CAUTION***—After moving engine, check and adjust accelerator pedal linkage and check clearance between Hydra-Matic filler tube and cowl assembly.
(3) If steps (1) and (2) do not correct interference, decrease turning angle of wheel by installing flat washers under head of wheel stop screw as follows: Remove wheel and drum, remove stopscrew and reinstall with flat washer under screw head. Recheck drag link clearance in extreme turn position, add additional washers until clearance is obtained. ***CAUTION***—This correction will increase turning radius and should only be made if clearance not obtained otherwise.

►***1953 CADILLAC POWER STEERING PUMP OIL SEAL PRODUCTION CHANGE (To prevent leaks at pump shaft)***—Starting with Engine No. 98475, a new seal with "garter" type spring replaces seal formerly used. New seal is interchangeable with previous type and should be used for replacement. Pumps equipped with new type seal are identifed by a daub of green paint on machined surface of pump between mounting bracket and pulley.

►***1952 CADILLAC POWER STEERING PUMP KIT CHANGE:*** Kit, Part No. 3630359, replaces kit formerly used for pump replacement on 1952 cars. New kit contains 1953 pump with return line reducing union and seal required for adaption to 1952 cars.

►***1953 CADILLAC VALVE BODY PRODUCTION CHANGE:*** Valve body now positively aligned to cover and gear housing by machined counterbores in cover and housing, eliminating need for Aligning Tool J-5283.

►***1953 PONTIAC POWER STEERING PUMP NOISE CORRECTION:*** Trouble may usually be traced to worn pump pulley-to-shaft keyway and key. To check, tighten attaching bolt to 15 ft. lbs. torque. If noise eliminated or changed, remove pulley, inspect key and shaft for wear. Replace with shaft and bearing assembly, pulley, key, bolt, plain washer and lockwasher contained in Shaft and Pulley Kit No. 517896. New bolt, Part No. 181636 (⅜"-24 x ⅞") must be tightened to 50-55 ft. lbs. torque.

►***1953 PONTIAC HYDRAULIC PUMP CHANGE***—Changed to Vickers (Vane Type) Pump with early September, 1953 production.

►***1953 PONTIAC PUMP BRACKET INTERFERENCE CORRECTION: (Pump Belt Tension Cannot Be Properly Adjusted)***—This condition may be due to interference between pump bracket and pump body. To correct, loosen pump body and allow it to fall free. Grind point of interference on bracket to give necessary clearance between bracket and body.

►***1953 STUDEBAKER POWER STEERING GEAR REPLACEMENT BALL SET:*** A ball set kit, Part No. 534858 containing 30 matched balls for use in servicing shaft and worm nut is available. It is important that matched sets of balls be used for replacement rather than single balls.

►*1954 VICKERS PUMP FRONT SHAFT SEAL PRODUCTION CHANGE (To Reduce Leaks):* Front shaft seal, Part No. 5681410, replaces Vickers Seal, Part No. 5665833, used in early production. New seal has greater lip pressure than previous one. A hardened shaft, Part No. 5681681, **must** be used with new seal

CONTINUED ON NEXT PAGE

SAGINAW (G.M.) C nt.

and may be used with old type seal. New shaft and seal are carried in package, Part No. 5681951. Pumps with new seal have smaller reservoir and are marked with daub of green paint on front of hub body instead of yellow daub at same place on earlier pumps. New hardened shaft is identified by a daub of green paint on threaded end of shaft or by a machined groove on the .75" diameter adjacent to splined end of shaft. To service pumps built after change use Master Kit, Part No. 5681964, and for those built prior to change use Master Kit, Part No. 5682130 (includes new shaft and seal).

►*1954 CADILLAC "CHATTER" CORRECTION:* Some cases of chatter (not chuckle) may be noted on cars built previous to Engine No. 01688 when making light turns or parking. Noise is particularly noticeable after reversing direction of steering wheel rotation when backing into a parking space. To correct, replace valve body assembly.

►*1953 PONTIAC WORM BEARING THRUST NUT CHANGE:* Tanged washer and locknut have been replaced by stake type nut.Adjustments remain unchanged.

►*1954 CHEVROLET LEAD OR WANDER CORRECTION:* Generally can be attributed to improper assembly of valve body assembly or improper usage of "O" ring seals. Trouble in valve body assembly can be checked by end motion of steering shaft with respect to its housing while oscillating pitman arm between right and left turn positions. Measurement in excess of .002" indicates that valve has excessive free movement in the valve body and can be allowing fluid to pass to power cylinder. If in excess of .002" check valve spool for proper installation and check for proper "O" ring usage. Turn valve spool over and recheck. If endplay still excessive, replace valve body assembly.

►*1953-54 LINCOLN ROTOR SHAFT BEARING INSTALLATION CAUTION:* Two types of bearings presently available. Use only Part No. 7RA-10094-A as a replacement instead of 7RA-10094-B. Nylon grease retainer in "B" design bearing wrinkles and becomes rigid allowing grease to escape. In "A" design (neoprene) this does not occur. Bearings are interchangeable when used on electric generator assemblies.

►*1953 OLDSMOBILE VALVE BODY "O" RING SEAL PRODUCTION CHANGE:* 1953 "O" ring seals are smaller in cross-sectional area than on previous models. If used on earlier models leaks will occur.

►*1954 PONTIAC BELT ADJUSTMENT CORRECTION:* In some cases it is not possible to adjust belt tension as specified due to interference between pump body and bracket. If belt is in good condition, place flat washer on each of three mounting studs, under bracket, to raise bracket and pump.

►*1953 STUDEBAKER RESERVOIR GASKET CHANGE:* New gasket, Part No. 534705 (same number as previous gasket), made of light tan, paper-like material, replaces gasket made of synthetic rubber and cork, of dark color and granular texture. Old type was subject to cutting on reservoir wall when cover tightened and did not provide a good seal when used more than once.

►*CADILLAC (1952-55) BLEEDING OF POWER STEERING SYSTEM PROCEDURE CHANGE:* The following procedure supersedes previous instructions for bleeding the system: Raise front end of car and place on jack stands. Remove tank cover holddown screw and remove tank cover and gasket. Fill oil tank to proper level and turn steering wheel from left to right to expel air from internal circuits (*CAUTION*–Do not force wheel against stops). Start engine and run at 1500 RPM for two minutes. Turn wheels from left to right, being careful not to force wheels against stops. Recheck fluid level and fill as required. Lower front end of car and turn wheels from left to right and inspect gear, pump hoses and connections for leaks. Stop engine, recheck oil level, install tank cover and gasket.

►*1955 BUICK STEERING SHAFT BUSHING PRODUCTION CHANGE & STEERING SHAFT RATTLE CORRECTION:* A new nylon, spring loaded, steering shaft upper bearing, Part No. 1169623, is used in production and is available for service replacement. Replace the former fabric bearing, Part No. 5664839 to eliminate steering shaft rattle and chucking noises.

►*1955 PONTIAC POWER ST. NOISE CORRECTION:* Noise may be caused by the power steering pump, or air in the system. Should the fluid appear cloudy, it is an indication of water in the system. Correct by replacing the fluid as follows: Remove pump return pipe and pump system as clear as possible. Fill with new fluid and cycle the steering from extreme right to extreme left until fluid being pumped through return hose is clear. Reconnect hose, fill reservoir and again cycle unit while pump is operating until there is no evidence of air bubbles in the reservoir. Fill reservoir and install cover.

►*1955 PONTIAC POWER ST. VALVE CENTERING SPRINGS & PLUNGER PRODUCTION CHANGE:* Early type springs are shorter (.660") and are plated. Plungers are grooved. Later type springs (.760") are plain steel (not plated), and plungers do not have a groove. These parts are interchangeable in complete sets only.

►*1955 BUICK GEAR VALVE-TO-CYLINDER TUBE UNIVERSAL FITTING ELBOW PRODUCTION CHANGE:* 90° universal fitting elbow and bolt previously used at valve end has been changed to a straight in type fitting. Fitting change required reforming of tubes by adding a bend to accommodate the straight in type fitting. Since serial number change points are not available, it will be necessary to determine type fitting on valve when ordering replacement part. Use of the 90° universal fitting bolt at other locations in the steering gear are not affected by this change.

DESCRIPTION

Steering Gear consists of a conventional Saginaw "re-circulating ball bearing worm-and-nut" type steering gear with addition of a hydraulic power mechanism to assist the manual operation so that the turning effort required at the steering wheel is greatly reduced. The hydraulic assist action begins when the turning effort at the rim of the steering wheel becomes 3-4 lbs. and provides a proportional share of the turning effort so that the pull required on the steering wheel rim should not exceed 8-9 lbs. for all normal operation. Since the hydraulic assist is only effective when a pull of 3-4 lbs. or greater is being exerted at the steering wheel rim, the driver retains the normal "feel" of steering and the steering action is conventional except for lesser effort required. Hydraulic elements are:

Hydraulic Power Mechanism—Consists of a single double-acting cylinder with the piston rod linked to a power rack meshing with a gear sector on the steering gear pitman arm. Cylinder assembly is mounted on steering gear housing (directly above or to one side of worm shaft) with an adapter closing the open or mounting end of the cylinder (adapter has "O" ring type seals on its outer circumference and a spring-loaded type piston rod seal). A rack-and-gear adjustment is provided consisting of a shim pack installed between the power rack cover and the housing to regulate the clearance between rack and guide on inner side of cover.

Control Valve Assembly—Located within valve housing directly above steering gear worm housing. Consists of a valve spool mounted concentrically on the worm shaft between two thrust washers which allow an up-and-down movement of the shaft of approximately .030" to actuate the valve. Spool is normally centered in the housing by five sets of centering plungers (set consists of two plungers with heavy coil spring between them) which contact the inner races of the thrust bearings and the ends of the valve housing. Whenever the thrust load on the worm shaft is sufficient to overcome the spring tension (as when pull on rim of steering wheel exceeds 3-4 lbs.), the worm shaft moves endwise and the valve spool directs oil pressure to proper end of power cylinder to provide hydraulic assistance (spool also opens return line from opposite end of cylinder so that displaced oil can return to reservoir). A check valve mounted in the valve housing allows the steering gear to be operated manually when the engine is not running (valve allows oil to bypass pump and flow freely from one end of the cylinder to the other).

Pump & Reservoir Assembly—Hydraulic pump is belt driven from the engine crankshaft and supplies oil pressure for the hydraulic assist cylinder. Pump operates continuously when the engine is running but a flow control valve recirculates oil within the pump when it is not needed for hydraulic assist operation. A relief valve is also provided to limit pump pressure. The reservoir is mounted directly above pump and supplies oil as needed.

Pump Note—Both Eaton (Rotor type) and Vickers (Vane type) pumps are used. Both pumps operate similarly but overhaul procedure is different.

ADJUSTMENT

►***ADJUSTMENT CAUTION—Whenever hydraulic system disturbed (by disconnecting lines, removal or installation of units, etc.), hydraulic system must be bled to remove air. See Bleeding Hydraulic System.***

1952-54 MODELS

►*LINCOLN ADJUSTMENT NOTE:* All adjustments of steering gear are to be made with unit removed from vehicle and disassembled. *See Overhaul.*

C NTINUED ON NEXT PAGE

SAGINAW (G.M.) Cont.

▷*OLDSMOBILE & STUDEBAKER ADJUSTMENT NOTE:* All adjustments of steering gear, except high spot adjustment, are to be made with unit out of car. *See Overhaul.*

Adjustments on Car: *CAUTION—BEFORE MAKING ADJUSTMENTS,* disconnect drag link at pitman arm, check tightness of pitman arm nut, check steering gear for binding by turning steering wheel slowly from one end position to the other *(CAUTION*—Do not turn steering gear hard against stops in end position to avoid damage to ball nut mechanism). Correct any binding due to misalignment before attempting to adjust steering gear.

Cadillac Alignment Note—Check alignment as follows: Loosen all three gear-to-frame mounting screws, tighten front screw only, check clearance between housing and frame at rear mounting screws and shim as required to fill the gap. If no clearance noted at rear screws, loosen front screw and tighten rear screws. Check clearance at front screw and shim as required to fill the gap. Tighten all three screws to 40-50 ft. lbs. torque. Recheck steering gear for freedom from binding.

Off-Center Pre-load Check (Unit on Car)— Proceed as follows:

Buick—Disconnect pitman arm from intermediate tie rod, then loosen four corner bolts of the power rack guide cover about 1/2 turn or just enough to assure lash between power rack and pitman shaft sector (NOTE—If bolts loosened too much, rack will bind on sector teeth). Turn steering wheel 2-3/4 turns from either extreme position to center ball nut on the central "high point" of pitman shaft sector (At this position center spoke of wheel should be straight down). Turn pitman shaft adjusting screw clockwise until lash between pitman shaft sector and ball nut is just removed (check by working pitman arm), then tighten locknut. Turn steering wheel two turns either way from central position and check pull with scale at rim of wheel and pulling at 90° to spoke. This should be 3/8-3/4 lb. (1952-53), 1/2-1 lb. (1954).

Cadillac—Disconnect drag link at pitman arm. Back off power rack and pitman shaft adjusting screws at least 1/2 turn. Using spring scale, check "off-center" pull through at rim of steering wheel. This should be 7/8-1 1/8 lbs. (1952-53), 3/8-3/4 lb. (1954).

▷*NOTE*—If readings outside above limits it will be necessary to remove unit from car.

Pitman Shaft Adjustments—*Two separate adjustments required as f ll ws:*

Oldsmobile & Pontiac Adjustment Note—Special "offset" screwdriver required for this adjustment.

Studebaker Adjustment Note—Steering Gear Adjusting Tool J-5563 is used in lieu of steering wheel for pitman shaft adjustment.

1) High Spot or Pitman Shaft-to-Ball Nut Lash (Pitman Shaft Endplay)—Loosen power rack cover bolts. Turn steering wheel slowly through its full range to check for freedom of movement, then turn wheel back to midway position to center ball nut on central high point of pitman shaft. Turn steering wheel shaft 45° right or left of center. Place spring scale on spoke of wheel at rim and pull on scale, at a 90° angle to spoke, to turn steering wheel. Adjust pitman shaft adjusting screw so that pull on 9" radius to turn wheel smoothly over center high spot is:

Buick—1/2-3/4 lb. higher than in "Off-Center Pre-Load Check".

Cadillac—1/2-1 lb. higher than in "Off-Center Pre-Load Check".

Chevrolet—1 1/8—1 1/2 lbs.

Oldsmobile—1 3/4 lbs. maximum.

Pontiac—1-1 1/2 lbs.

Studebaker—1/2-1 lb.

Note—Lincoln "High Spot" adjustment included in overhaul.

Record reading for Power Rack Guide adjustment.

2) Pitman Shaft-to-Power Rack Lash (Power Rack Guide Adjustment)—Tighten power rack cover bolts. Turn steering wheel slowly through its full range to check for freedom of movement, then turn wheel back to center position. Turn steering wheel shaft 45° right or left of center. Place spring scale on spoke of wheel at rim and pull on scale, at a 90° angle to spoke, to turn steering wheel. If power rack cover shims have been selected properly there will be a preload in addition to over-center or pitman shaft adjustment when column shaft is rotated past center high spot as follows:

Buick—1/4-1/2 lb. higher than in 1) or 1 1/4—2 1/4 lbs.

Cadillac—1/8-1/4 lb. higher than in 1) or 1 1/4—2 lbs.

Chevrolet—1/8 lb.

Pontiac—No increase.

Note—Lincoln, Oldsmobile, and Studebaker "Power Rack Guide Adjustment" included in overhaul.

If adjustment is above or below that specified, add or subtract shims. Subtracting shims will decrease reading and adding shims will increase reading.

NOTE—Add or subtract one .003" shim (.003", .005", and .010" available) at a time until desired reading is reached. After all adjustments made, there should be no perceptible backlash in sector shaft when column shaft is rotated 30° either side of center. Recheck of over-center adjustment after complete assembly of column jacket, gear one turn off center, and pitman arm disconnected, should give following minimum to maximum readings:

Buick—1 1/8—2 lbs.

Cadillac—1-2 lbs.

Chevrolet—1-5/8 lbs. maximum.

Pontiac—1—1 1/2 lbs.

Worm Thrust Bearing Adjustment—This adjustment normally made when assembling steering gear and can only be made with steering gear out of car. If adjustment required in service, remove steering gear from car. *For adjustment procedure see Steering Gear Overhaul (following).*

PUMP DRIVE BELT ADJUSTMENT:

Buick—Belt should have 3/8" deflection with thumb pressure applied midway between pulleys. To adjust, loosen pump mounting bolts and shift pump horizontally (bolt holes in bracket slotted).

Cadillac—If belt squeals on hard turns, belt is too loose. Adjust by loosening pump to bracket screws and moving pump outward to torque wrench reading of 13-15 ft. lbs. Tighten screws to 25-29 ft. lbs.

Chevrolet—Loosen inner bracket to pump and outer bracket to pump fixed mounting bolts. Insert Belt Tension Adjusting Tool J-5470 between pulley and pump with inner end of tool resting under pulley hub and not in tool over head of outer fixed mounting bolt. Pull outward on torque wrench until a torque of 14 ft. lbs. is obtained. Tighten mounting bolt at slotted hole, remove tool and torque wrench, then tighten fixed mounting bolt.

Lincoln—Lift up on pulley to tighten belt. Do not lift on reservoir. Belt tension should have 5-7 lbs. pull at 1/4" deflection. Torque 35-50 ft. lbs.

Oldsmobile—Use Belt Tension Adjusting Tool J-5192 and Torque Wrench. Loosen inner and outer bracket-to-pump mounting screws (inner screw hole slotted), insert adjusting tool between pulley and pump with inner end of tool under smaller diameter of pulley hub and notch in tool over head of outer mounting screw. Pull outward on torque wrench until reading of 30 ft. lbs. (new belt), 20 ft. lbs. (broken-in belt) obtained, tighten mounting screws before slacking off on wrench. This setting corresponds to belt deflection of 7/8" with 25 lbs. pressure midway between pump and fan pulleys.

Pontiac—Loosen pump to bracket attaching bolts two full turns so pump falls free of own weight. Place pump belt tightener J-5452 (Eaton type pump); J-5574 (Vickers type pump) over head of upper bolt so that curved portion of tool fits under pulley. Using 1/2" drive 0-100 ft. lbs. torque wrench perpendicular to tool, apply torque of 43-45 ft. lbs. (Eaton Pump); 58-65 ft. lbs. (Vickers Pump—New belt); 51-53 ft. lbs. (Vickers Pump—Used belt). Tighten lower pump to bracket attaching bolt. Remove tool and tighten upper attaching bolt.

▷1953 Pontiac Pump Bracket Interference Correction (Pump Belt Tension Cannot be Properly Adjusted)—This condition can be due to interference between pump bracket and pump body. To correct, loosen pump body and allow it to fall free. Grind off point of interference on bracket to give necessary clearance between bracket and body.

Studebaker—Belt deflection should be 1/4-3/8" with pull of four lbs. at point midway between pump and crankshaft pulleys. Slots provided at mounting screws in bracket to permit shifting pump body to secure proper belt tension.

1955 MODELS

ADJUSTMENT: (ON CAR)—Before making adjustments, disconnect drag link at pitman arm, check tightness of pitman arm nut, and check steering gear for binding by turning steering wheel slowly from extreme right to extreme left *(CAUTION*—Do not turn steering wheel hard against stops in end position to avoid damage to the assembly). Correct any binding due to misalignment before making adjustments. Loosen four corner bolts of power rack guide cover about one-half turn or just enough for lash between rack and sector.

▷*BLEEDING HYDRAULIC SYSTEM NOTE: System must be bled to remove air whenever lines are disconnected or units removed and installed.*

CONTINUED ON NEXT PAGE

SAGINAW (G.M.) C nt.

High Spot Adjustment (Pitman Shaft Sector-to-Ball Nut Lash): As follows:

Buick—Turn wheel to extreme right or left position. Attach scale J-544-A to a spoke at rim of wheel and, while pulling scale at 90° to spoke, check pull required to turn wheel steadily in the range where lash normally exists between pitman shaft sector and ball nut (lash range is 1/8 turn of steering wheel from either extreme position). Reading on scale should be between 1/2 and 7/8 lbs. (If not within these limits, check steering column alignment at frame mounting bolts, faulty steering shaft upper bearing, or worm thrust bearing adjustment). If reading within limits, turn steering wheel 2¾ turns from either extreme position to center ball nut on "high-spot" of sector (center spoke of wheel should be straight down). Turn pitman shaft adjusting screw clockwise until lash between sector and ball nut is removed (check by working pitman arm), then tighten locknut. Turn steering wheel 2 turns in either direction from center position and check pull with scale. This should be between 1/2 and 7/8 lb., record this reading for reference. Turn steering wheel back to near center position and check pull required to turn wheel through "high spot". Turn pitman adjusting screw clockwise as required to obtain a scale reading ½-¾ lb. higher than that obtained at end position of travel, after locknut tightened. Record this latest scale reading for "Power Rack Adjustment" reference, below.

Cadillac—Check flexible steering shaft coupling for distortion and correct as necessary. Using spring scale J-544-A, check the "off-center" pull through at rim of steering wheel which should be 3/8 to 3/4 lb. (If reading not within these limits, remove steering gear and check thrust bearing locknut torque which should be 30 ft. lbs.). Check for binding or rough bearings in upper and lower thrust bearing retainers. Adjust pitman shaft endplay screw until pull through center is ½-1 lb. greater than pull at one full turn off center.

Lincoln—Adjustments on car are not recommended, and should be performed when steering gear is removed for overhaul or when being installed.

Oldsmobile—Turn steering wheel through full range (5½ turns), to check for free action; then, turn wheel back one full turn from right or left position. This positions wheel in middle of lash range. Attach spring scale J-544-A to spoke of wheel at the rim, and while pulling on scale steadily at 90° to spoke, observe amount of pull required to turn wheel through lash range (record this reading for reference). Turn wheel to center position (2¾ turns from full right or full left) and observe the amount of pull required to turn wheel through the "high spot" (center) range. This should be 5/8 lb. more than the amount recorded in lash range. Adjust pitman shaft adjusting screw to obtain the correct amount of pull at the "high-spot" and tighten adjusting screw locknut.

P ntiac—Loosen pitman shaft adjusting screw locknut and back off adjusting screw a few turns, using an offset screwdriver. With steering gear on "high-spot" (center position), adjust pitman shaft thrust screw so that pulling on steering wheel rim through a 3" arc using J-544-A spring scale, is 1-1¾ lbs., through the center "high-spot". Tighten locknut and recheck pull through "high-spot".

Studebaker—The "high -spot" and power rack adjustments should be made while steering unit is out of car, although minor changes can be made in "high-spot" adjustment with the unit installed.

Power Rack Guide Adjustment: This adjustment must be made after "High Spot" Adjustment completed.

Buick—Tighten the four power rack guide cover bolts and recheck pull through the "high spot". The scale reading should be ¼ to ½ lb. higher than the final reading taken in "High Spot" Adjustment (above), or between 1 1/8 & 2 lbs. If reading is not within these limits, add or remove shims as required to obtain the specified pull through the "high spot". Guide cover shims are available in .003" and .005" thicknesses.

Cadillac—Using tool J-5648, tighten the power rack adjusting screw so that "high spot" pull through (see above), is 1/8 to 1/4 lb. higher than that obtained in "High Spot" Adjustment. This should be measured at rim of wheel through an arc not exceeding 3".

Lincoln—Adjustments on car are not recommended, and should be performed when steering gear is removed for overhaul or when being installed.

Oldsmobile—Tighten power rack guide cover bolts evenly, being sure that bolt threads do not pick up shims when tightening cover to housing. Attach spring scale to wheel rim and check pull through "high spot". If pull is increased over the final reading taken in "High Spot" Adjustment (above), add shims of .003" thickness, one at a time until pull decreased to original reading. If pull remains the same as final reading, remove shims of .003" thickness, one at a time, until pull is increased above original amount, then add one .003" shim. Recheck pull through the "no lash" range which should not be more than 1¼ lbs. Pull required in pull through "High spot" should not be greater than 1¾ lbs.

Pontiac—Tighten four power rack guide cover bolts evenly. Recheck pull through "high spot" position which should be 1½ lbs. maximum. If "high spot" pull increased after power rack guide cover bolts tightened. above the maximum (1½ lbs.), add .003" shims under cover until last shim added decreases the load. If pull through "high spot" remains the same after cover bolts tightened, remove .003" shims until load increases above that obtained in final check of "High Spot" Adjustment. Then add one .003" shim.

Studebaker—The "high spot" and power rack adjustments should be made while steering unit is out of car.

Worm Thrust Bearing Adjustment: This adjustment made with steering gear out of car. If adjustment required in service, remove steering gear. See "Steering Gear Overhaul" below, for adjustment procedure.

Pump Drive Belt Adjustment: Proceed as follows:

Buick—Adjust belt tension so that pulley will slip in belt when 40-45 ft. lbs. (new belt), 30-35 ft. lbs. (used belt), is applied to pulley nut with a torque wrench.

Cadillac—Loosen pump to mounting bracket screws and move pump outward until belt is tight. With shift lever in "N" race engine while turning steering wheel. If belt squeals, it is too loose and must be retightened.

Linc ln—Belt tension should be 5-7 lbs. pull with ¼" belt deflection.

Oldsm bile—Loosen pump to bracket attaching bolts and place tool J-5398 under pump pulley and over attaching bolts, With torque wrench, adjust drive belt tension to 30 ft. lbs. This adjustment corresponds to a belt deflection of 7/8" with 25 lbs. pull applied midway between pump pulley and fan.

Pontiac—Loosen pump to bracket bolts two full turns so pump falls of its own weight. Place pump belt tightener J-5574, over head of hinge bolt, and using a torque wrench perpendicular to tool, tighten belt to 58-65 ft. lbs. (new), 51-53 ft. lbs. (used). Tighten clamp bolt.

Studebaker—With spring scale at right angles to belt, pull on scale should be 4 lbs., with a belt deflection of 1/4" to 3/8". Slots are provided at mounting bracket screws in bracket to permit shifting pump body for proper tension.

HYDRAULIC PRESSURE TESTS

Disconnect hose at lower pump union (nearest engine). Install Gauge J-5176 (Lincoln Gauge No. 3500), with gauge valve closed. Connect hose to fitting on valve side of gauge. **Open gaug valve** and run engine at idle speed. Test as follows:

1) With gauge valve open and engine idling, turn steering wheel through entire travel from one end position to the other with the wheels on the ground *(CAUTION—* Do not hold steering wheel in extreme position for extended period). Oil pressure on gauge should not be less than indicated in table below. If pressure is less than indicated in table, test as outlined in **(2)** below.

Car	Engine RPM	①Pump Pr ssure
Buick	450	700 lbs.
Cadillac (1952-53)	400	700 lbs.
Cadillac (1954-55)	400	900 lbs.
Chevrolet	475	750 lbs.
Lincoln (1953)	400-425	700 lbs.
Lincoln (1954-55)	425-450	700 - 900 lbs.
Oldsmobile	400	650 lbs.
Pontiac	375	650 lbs.

①—Maximum pressure should not be less than lowest indicated pressure.

2) If pressure low in test above, slowly close gauge valve and make quick test of pump pressure *(CAUTION—*Do not leave valve closed more than 15 seconds). If pressure increases to, or is greater than the pressures indicated in table (above), pump is alright and trouble is in steering gear or in oil lines. If pressure equally low in both tests (or not more than 50 lbs. increase in test **(2)**, trouble is in oil pump. If pressure increases more than 50 lbs. in test **(2)** but is still below normal, both pump and steering gear or oil lines are faulty.

TROUBLE SHOOTING

If operation not satisfactory, check as follows:

HARD STEERING (Particularly When Parking): Check to make certain that hard steering exists by measuring steering wheel pull under extreme conditions as follows: With car parked, apply brakes, idle engine, turn steering wheel from side to side to bring oil temperature up to 170°F. (similar to condition existing

CONTINUED ON NEXT PAGE

SAGINAW (G.M.) C nt.

after excessive turning or on hot days). Use 15 lb spring scale (Tool J-5178) hooked to wheel rim at spoke to check pull required to rotate wheel steadily (measure pull at 90° to spoke). If pull exceeds 10 lbs., check following causes:

1) Pump drive belt loose or pump defective. Adjust drive belt and test pump pressure. See Testing Hydraulic Oil Pressure.
2) Low Oil Level in Reservoir. Check and fill reservoir to proper level. If oil level low, check entire system for evidence of leakage.
3) Air in Hydraulic System (may be noted by noisy pump action). Tighten valve cover screws and all hydraulic line connections. Bleed system.
4) Steering gear not properly lubricated or adjustments too tight. See Lubrication and Adjustment.
5) Steering tube misaligned or tight upper bearing See Steering Gear alignment (under Adjustment).
6) Linkage too tight, bent, or misaligned.
7) Tires under-inflated
8) Low oil pressure. See Testing Hydraulic Oil Pressure.

EXCESSIVE PLAY OR LOOSENESS (May cause Front Wheel Shimmy or whe l kickback):

1) Excessive lash in steering gear (between pitman shaft gear sector and ball nut or power rack) or in steering linkage. See Adjustment.
2) Loose worm thrust bearing adjustment (see Adjustment) or valve spool sticking in housing.
3) Air in hydraulic system (may be noted by noisy pump action). Tighten valve cover screws and all hydraulic line connections. Bleed system.

POOR CENTERING OF STEERING WHEEL OR RECOVERY FROM TURNS:

1) Binding of steering shaft due to misalignment or tight bearings. Check alignment and adjustments.
2) Valve spool sticking in valve housing or defective valve centering plunger springs.
3) One front tire under-inflated.

STEERING GEAR NOISY:

1) Loose pitman shaft adjustments (excessive lash at ball nut or power rack). See Adjustment.
2) Loose worm thrust bearing. See Adjustment.
3) Loose power piston-to-power rack pin.
4) Steering gear mounting loose (noisy on turns).

HYDRAULIC PUMP NOISY:

1) Air in system due to low oil level, loose intake hose connections, defective shaft or steering gear seals.
2) Pump drive belt too tight. See Belt Adjustment
3) Oil hoses grounded against engine. Check and reroute hoses to provide clearance.
4) Reservoir air vent clogged, clogged intake line or filter, sludge or dirt in pump, oil too heavy. Clean out pump and reservoir and refill with correct oil
5) Pump bearings, shaft, or other parts worn. Pump vanes sticking (Vickers Pump).
6) Relief valve chattering Check for sticking valve, clean and free up valve.

LOW OIL PRESSURE: S T sting (following).

1) Drive belt loose or worn See Belt Adjustment.
2) Oil level too low or wrong type oil (too light).
3) Pump worn or defective Pump relief valve stuck open or spring weak. Flow control valve stuck open.
4) Oil filter clogged (cars with Eaton pump).
5) Internal or external oil leaks (following)

OIL LEAKAGE:

1) Defective "O" ring seals due to over-torquing, burrs in recesses, cocked seals, unclean bores, seals not protected from threads on shafts, sharp edges.
2) Loose connections or worn hoses
3) Oil pump shaft seal installed backwards (install with two holes in seal casing toward front or outside of pump (pulley end)
4) Improper installation of plug and "O" ring (Vickers Pump). Must be installed to pump cover flow control valve from rear (chamfer end) until end of plug is just past snap ring groove
5) Hydraulic oil leaking into steering gear housing, upper housing seal or cylinder adapter seal (piston rod seal) leaking.

LUBRICATION

Power Steering Hydraulic System: (Checking Fluid Level)—Check at 1000 mile intervals (2000 miles on Cadillac, 5000 miles on Studebaker)

Buick—Thoroughly clean area around filler plug in top of reservoir, remove filler plug (has dipstick underneath), insert dipstick in reservoir with **plug seated on edge of filler opening,** add oil as required to bring level up to mark on dipstick

Cadillac, Chevrolet, Oldsmobile, Pontiac - Clean reservoir cover area, remove cover and gasket. Oil level should be at oil level mark on side of reservoir (1" below top edge of reservoir), Add oil as required. Torque cover screws to 20 ft lbs. (On Pontiac replace cover and retaining ring).

Lincoln—With engine off, remove reservoir dipstick by turning counter-clockwise and pulling out. Level of fluid should be to the line marked "full" on the stick. *Do not overfill.*

Studebaker—Maintain fluid level at mark indicated on side of reservoir.

Recommended Oil—Use same oil as used in the automatic transmission on the car (Dynaflow Drive Fluid, Hydra-Matic Drive Fluid, or Automatic Transmission Fluid Type A with AQ-ATF No.).

Steering Gear (Worm & Ball Nut): Check at 1000 mile intervals (2000 on Cadillac, 5000 on Studebaker) Maintain lubricant level at filler plug hole. **Do not** use pressure gun to add lubricant (will damage worm and power piston rod seals). Use lubricants:

Buick & Studebaker—Multipurpose gear lubricant SAE 90 (same as for synchro-mesh transmission).

Lincoln—Ford Motor Company Specification M-4738 **or its absolute equivalent.**

Others—Approved steering gear lubricant.

BLEEDING HYDRAULIC SYSTEM: *Required whenever hydraulic system disturbed (by disconnecting lines, removal or installation of units, etc.).*

Buick—Fill reservoir to proper level (see Lubrication). On cars with Vickers (vane type) pump, remove pipe plug from top of pump manifold until oil begins to flow from this opening, then install plug just tight enough to prevent oil flowing out. Allow car to stand for 5 minutes Start engine and run at approximately 1000 RPM for 2-3 minutes, then turn steering wheel from wheel from left to right extreme position to work air out of power cylinder. Repeat as necessary until all air worked out (pump will quiet down as air removed). Tighten plug in pump manifold, recheck oil level. Road test car with some parking and high speed driving, if possible.

Cadillac, Chevrolet, Oldsmobile, Pontiac - Fill reservoir. Let car stand for two minutes. Crank engine with ignition off and turn steering wheel at the same time to eliminate air pockets from power cylinder while maintaining oil level in reservoir. Start engine and run at idle speed for 2 minutes. Check oil level and inspect entire system for leaks. Increase engine speed to 1500 RPM and run it at this speed until air bubbles cease to appear in reservoir (turn wheels from side to side to assist process, lightly contacting stops). Recheck oil level and refill as required.

Lincoln—Fill oil reservoir to proper level (see Lubrication). Start engine and run at idle speed for two minutes. Recheck fluid level and inspect hoses and connections for leaks. Increase engine speed to 1000 RPM and turn wheels from right to left five or six times. DO NOT HIT STOPS. Recheck for leaks. Check oil level and refill as required.

Oldsmobile—Fill reservoir to proper level and maintain level during bleeding operation. Run engine at idle speed for 30 seconds, then increase speed to 1500 RPM for 1 minute. Raise front end of car and rotate steering wheel through its full travel several times to eliminate air from system Recheck fluid level in reservoir

REMOVAL & INSTALLATION

1953 BUICK SERIES 40

BUICK (Series 40) Steering Gear Removal: Disconnect pitman arm from steering tie rod, remove pitman arm from steering shaft using Puller J-1025. Remove air cleaner assembly, disconnect fuel and vacuum lines from carburetor and carefully move them out of the way. Disconnect clutch linkage anti-rattle spring from idler lever pin bracket and disconnect upper shift rod from control shaft lower lever. Disconnect wires from horn cable connector, back-up light switch, and neutral safety switch. Pull speedometer cable from clip and remove horn cable connector from column jacket. Disconnect one end of cross-brace at cutout in cowl and swing brace to one side. Move front seat all the way back for clearance. Remove dash insulator retainer and steering column pad, remove pedal plate attached to toe panel (under floor mat). Remove steering wheel (see data below), upper bearing spring and spring seat, shift control lever and direction signal lever. Disconnect direction signal switch wires from fuse block terminals. Remove steering column bracket (*CAUTION*—save all spacers located between bracket and support bracket on instrument panel—these must be re-installed). Remove screws attaching front end of left air intake duct to fender skirt, coat rubber grommet on duct with Lubriplate (to aid in pulling it through hole in skirt), disconnect the flexible hose at the clamp, remove bolt attaching rear end of duct to rear fender skirt (remove

CONTINUED ON NEXT PAGE

SAGINAW (G.M.) C nt.

from inside hose), remove air duct. Disconnect pressure and return line hydraulic hoses at the pump *(CAUTION*—cap pump fittings and plug hoses to prevent oil spilling out). Remove steering gear-to-frame bolts and clamps *(CAUTION*—support column to prevent damage to column jacket). Move steering gear assembly to rear as far as possible, turn assembly so that pitman arm shaft upward, lift forward end up between engine and fender and move it forward and out of the car *(CAUTION*—a helper should guide column jacket and signal switch housing through cutout in cowl panel to avoid damaging these parts).

Steering Wheel Removal—On solid spoke steering wheel, pry out horn button cap, remove contact cup, spring, and contact plate (attached to wheel hub by three screws and spacer bushings). On flexible steering wheel, pry off monogram and bezel assembly, remove horn button operating wheel (attached by three screws). On all models, set direction signal in "off" position. Flatten lockwasher tab and back off steering wheel nut several turns but **do not remove nut.** Use Puller J-1566 and adapter to pull wheel back to the nut *(CAUTION*—if wheel hub tight on shaft, apply moderate strain with puller, tap end of puller screw to break hub loose—this will prevent distorting wheel hub). Remove puller, remove steering wheel nut, lift steering wheel off.

Installation: Install steering gear in car by reversing removal procedure (above) with particular attention to the following points:

Tightening Mounting Bolts—Install frame bracket bolts but leave these bolts loose until after steering column bracket and ALL ORIGINAL SPACERS installed, center the steering column in the dash cutout and tighten bracket bolts securely, then tighten frame bracket bolts to 30-35 ft.lbs. torque.

Installation Check—After steering gear installed, install steering wheel, turn wheel slowly from one extreme end position to the other to make sure no bind exists at any point. If bind noted, re-align steering gear in mounting brackets.

Oil Line Connections—Oil line hoses are marked (at pump end) and hose connections at pump have same marks: Pressure Line "PR," Return Line "RT."

►***CAUTION—Hose connection locations on Vickers and Eaton Pumps are reversed ("PR" connection nearest engine on Eaton pump, farthest from engine on Vickers.***

1952-53 BUICK SERIES 70
1953 BUICK SERIES 50

BUICK (Series 50 & 70) Steering Gear Removal: Remove battery cables from battery, then remove battery and battery heat deflector. Remove selector control rod from arm on shift safety switch. Remove bolts securing metal strip at rear end of fender skirt in wheel housing. Remove pitman arm-shaft nut, disconnect arm from shaft. Remove two bolts from upper clamp that secures steering gear to frame bracket. Remove hydraulic lines at pump, drain, then cap lines and ports in pump *(CAUTION*—Capping of lines and ports necessary to keep dirt out of pump and lines). Remove horn contact button, connection of backup light-safety starting switch from mast jacket, direction signal wires from fuse panel. Remove screws that secure mast jacket rubber retainer, pull retainer up about one foot on jacket. Remove metal section of floor board under brake pedal. Remove steering wheel (see data below). Loosen bolt from clamp securing mast jacket to hydraulic valve cover, then remove two bolts securing jacket to instrument panel *(CAUTION*—save all spacers located between bracket and support bracket on instrument panel—these must be re-installed). Cap steering shaft using Part No. J-5159 or cover with masking tape. Remove mast jacket from steering shaft by lifting jacket into car. Remove power steering unit by lifting up and forward into engine compartment.

Steering Wheel Removal—*See Buick Series 40 "Steering Wheel Removal" above.*

Installation: Install steering gear in car by reversing removal procedure (above) with particular attention to the following points:

Tightening Mounting Bolts—Before actually installing steering gear see that lower clamp securing gear to frame is in place but loose. Place two upper clamp bolts in position, then install only outer half of upper clamp securing gear to frame bracket. Replace gear in position, then install other half of upper clamp. Hold in position by installing nuts on clamp bolts but do not tighten at this time. When tightened, torque to 30-35 ft. lbs.

Installation Check & Oil Line Connections—See Buick Series 40 "Installation" above.

1954-55 BUICK, ALL SERIES

Removal: Remove battery and battery shield. Disconnect pressure and return line hoses from hydraulic pump and immediately install shipping caps on pump fittings to retain oil in pump. Drain hoses and install plugs in hose ends. Disconnect transmission shift rod from control shaft lower lever. On synchro-mesh cars only, remove selector lever from clamp on jacket by removing retainer and spring washer. Loosen bolt in clamp which secures column jacket to short tube in gear housing. Move front seal all the way back. Disconnect and remove horn cable connector from steering column jacket. On Dynaflow cars, disconnect wires from neutral safety switch and remove speed ratio dial light bulb holder from support on steering column jacket. On all cars, remove signal switch wires from fuse block under cowl. Cover steering column jacket with masking tape to prevent damage to finish. Remove steering wheel and upper bearing spring and spring seats. Cover the horn contact and threaded end of steering shaft with masking tape. Remove signal switch and transmission shift control levers. Detach the rubber insulator retainer from dash mat and pull it up about a foot on column jacket. Remove jute column pad. Measure vertical clearance between column jacket and lower surface of instrument panel and record this dimension so column can be installed in same position. Remove bolts holding cap to steering column bracket and disconnect bracket from instrument panel, then pull upward on column jacket to free it from steering gear. Remove cranking motor splash pan from car frame. Remove steering gear to frame lower bolts and clamps, then loosen upper bolts enough so that gear can be tilted sideways to provide room for pitman arm puller. Remove pitman arm. With another man inside the car to guide column and prevent damage, carefully lift steering gear assembly up and forward out of engine compartment, leaving column jacket assembly in car.

INSTALLATION: Reverse the removal procedure and note the following: When installing column jacket assembly over steering shaft, place Bearing Protector J-5159 over serrated end of shaft to avoid damage to shaft upper bearing in jacket (slot in lower end of jacket must engage dowel pin in hydraulic valve cover). When mounting the gear and jacket assembly in brackets, make certain that column is properly positioned at instrument panel and tighten column bracket before tightening gear housing to frame, then check for bind as follows: Temporarily install steering wheel and use scale J-544-A to check pull required to turn wheel steadily through high point or no lash range. The pull should not be more than ¼ lb. more than before installation. If greater, check upper bearing in jacket. Connect pressure hose to lower union on pump, and return line hose to upper union.

STEERING WHEEL & HORN BUTTON OR RING REMOVAL: *See "1953 Buick Series 40" (abov).*

1952-54 CADILLAC

CADILLAC Steering Gear Removal from Car—Support front end of car on stands placed near outer ends of lower suspension arms with wheels approximately 10" off floor. Remove steering wheel (see data below), remove steering column upper and lower covers. Take out screws in steering column support bracket at instrument panel, and two screws attaching horn contact assembly to column jacket under instrument panel. Take out three screws in steering column cover on toeboard. Remove heater blower motor from heater and remove flexible air intake hose. Disconnect both oil line hoses at power unit *(CAUTION*—cap the hose connections and plug the hoses to prevent oil spilling out). Loosen steering column lower jacket clamp. Disconnect steering connecting rod at pitman arm. Remove left exhaust pipe at manifold. Remove three bolts attaching steering gear to frame side rail *(CAUTION*—save all shims found at these mounting bolts—these shims necessary to align steering gear). Carefully slide steering gear down and out of upper jacket and remove assembly from the car *(CAUTION*—use extreme care not to damage upper housing tube bearing).

Steering Wheel Removal—Disconnect horn wire from horn contact assembly on upper steering cover beneath instrument panel. Depress horn button and turn counter-clockwise to release locking ears. Remove button assembly and horn button spring. Remove steering wheel hub nut, then remove horn ring retainer, cushion, and horn ring. Mark steering wheel hub and shaft (to insure correct re-installations), use Puller J-1859 to remove steering wheel.

Steering Linkage Removal & Disassembly—Disconnect tie rod ends. Remove idler arm support screws from frame side member, pitman arm from shaft (Puller J-2162), and connecting link with tie rods, idler arm support, idler arm, and pitman arm attached. Remove cotter pin, adjusting and stop plugs, spring and ball seat, from left end of connecting link. Remove pitman arm. Remove inside ball seat, spring stop plug, spacer, and tie rod outer ball seat, to remove left tie rod. Remove cotter pin, plug, and outer ball seat from right end of connecting link. Remove idler arm. Remove inner ball seat, spring, stop plug, long spacer, cover, and ball seat

C NTINUED ON NEXT PA E

SAGINAW (G.M.) Cont.

to remove right tie rod. Loosen clamp screws, unscrew tie rod or tie rod end from clamp. Unscrew idler arm support from bushing.

Installation: Install steering gear in car by reversing removal procedure (above) with particular attention to the following points:

Steering Linkage - Install drag link end plugs tightly. Back off left end plug ¼-½ turn and right plug 7/8-1 turn (1952-53), back off left end plug 1/2-5/8 turn and right plug 1/4-1/2 turn (1954). Install idler arm support with seal until it bottoms, then back off 1/2-1½ turns, depending on position of bushing in idler arm. Connect pitman arm to steering connecting rod, turning end nut up tight and backing it off 1/2-5/8 turn. Torque pitman arm on shaft to 125-150 ft. lbs., idler arm support on frame side bar to 30 ft. lbs., tie rods to steering arms to 50-55 ft. lbs. Adjust toe-in, and drag link height. *NOTE* - Be sure open side of clamps are over open side of adjuster before tightening clamp nuts.

Worm Shaft Seal Protector Caution—Install Seal Protector J-5159 on upper end of steering shaft to prevent damage to upper housing tube bearing when sliding steering gear up into position.

Steering Gear Alignment—Install steering gear frame mounting bolts with same number and thickness of shims as were removed from between steering gear and frame, tighten mounting bolts to 40-50 ft.lbs. torque. Check upper steering column alignment in instrument panel recess and adjust, as necessary by adding or removing shims at frame mounting holes.

Steering Wheel Installation—Install wheel with marks on hub and shaft lined up, tighten nut to 45-50 ft.lbs. torque and stake nut to shaft to prevent loosening. Measure gap between bottom edge of horn ring and upper edge of direction signal switch carrier and slide steering jacket up or down as required to secure 3/16" gap at this point with horn ring in released position.

Oil Line Connections—Connect hose from upper "RT" fitting on pump to large union on steering gear valve body which is nearest frame side rail, connect hose from "PR" fitting to small union, on valve body, closest to exhaust manifold.

1955 CADILLAC

REMOVAL: (Gear Assembly)—Disconnect hoses from valve body on gear housing. Cap ends of hose to prevent loss of oil. Remove return port (large) fitting from valve body. Raise front end of car and place jack stands near outer ends of lower suspension arms. Disconnect pitman arm from drag link. Remove lower flange to coupling screws. (*NOTE*—Scribe marks on coupling and flange to assure correct positioning of steering wheel at assembly). Remove gear housing to frame side bar screws and remove gear housing.

INSTALLATION: (Gear Assembly)—Place assembly on frame side bar, guiding the lower flange onto coupling, and install gear to frame screws. (*NOTE*—Make certain that scribe marks on coupling and upper steering tube flange are aligned). Install lower flange to coupling nuts. (*NOTE*—After installing gear, check the flexible coupling for distortion. The coupling must rest flat with no visible bend or twist. If it is distorted, remove the lower steering column cover and lower clamp to jacket screw. Loosen steering jacket clamp screws at instrument panel, and slide complete steering jacket assembly up or down as required. Redrill lower clamp and jacket if necessary to install screw). Connect pitman arm to drag link.

REMOVAL: (Upper Steering Shaft)—Remove steering gear assembly (above). Disconnect battery ground strap and remove neutral safety switch and horn contact Remove horn button and spring and remove steering wheel hub nut. Remove horn retainer and horn ring. Remove steering wheel using Puller J-1859. Remove steering jacket tensioner spring and split ring Loosen lower steering jacket clamp, pry lower bearing retainer out of steering jacket and remove upper steering shaft through bottom of jacket

Upper Steering Shaft Lower Bearing Removal & Installation: With upper steering shaft removed, use a soldering iron, and remove upper tip on horn contact wire and remove plastic insulator. Pull the wire down through shaft and out opening at horn contact bushing. Remove bushing with wire from shaft Slide bearing retainer from shaft and press bearing from retainer To install, reverse removal procedure.

INSTALLATION: (Upper Steering Shaft)—Slide upper shaft into steering jacket, insert lower bearing retainer into jacket until retainer flange is tight against bottom of shaft, and temporarily tighten lower clamp. Install split ring and steering shaft tensioner spring over end of steering shaft Install steering wheel over splines on shaft with punch marks lined up. Install horn ring retainer and horn ring in position on steering wheel. Install steering wheel hub nut and tighten to 45-50 ft. lbs. Stake nut to shaft. Install spring and horn button. Loosen lower steering jacket clamp and work lower bearing retainer flange down from end of jacket until 3/16" clearance is obtained between horn ring and directional signal switch carrier. (*NOTE*—To obtain clearance, insert a screwdriver between lower bearing retainer and jacket. Twist screwdriver to move retainer down). Hold lower bearing retainer in position while tightening lower jacket clamp, making certain that lower edge of clamp is as close as possible to lower end of jacket.

STEERING SHAFT UPPER BEARING REMOVAL: Remove neutral safety switch and horn contact from lower steering column. Remove cotter key, dust shield and horseshoe retainer at lower shift lever on steering jacket and then disengage shift lever from shifter tube. Remove steering wheel, tensioner spring and split ring, and direction signal switch (see Upper Steering Shaft Removal above). Remove capscrews holding upper bearing retainer to steering jacket. Remove steering column lower cover. Remove Hydra-Matic shift dial indicator. Pull shifter tube out of steering jacket until shift detent on bearing retainer clears jacket, then screw bearing retainer from shifter tube. Press upper bearing from retainer.

REMOVAL: (Steering Column Assembly)— (*NOTE—Removal of the complete steering column assembly is only necessary when both upper and lower bearings must be replaced or if lower shift lever must be replaced).* Disconnect battery ground strap and remove direction signal switch and horn contact from lower steering jacket Remove brake pedal retaining screw. Raise car Disconnect manual control rod from lower shift lever Scribe marks on coupling and flange to assure correct positioning on assembly, then remove coupling to lower flange nuts. Remove brake pedal Loosen carpet on left front side and pull back from steering column toe plate and remove plate to floor board screws Remove stop light switch screws Remove steering jacket lower cover and remove Hydra-Matic indicator pointer. Disconnect direction signal switch wires at connector. Remove the small screw at bottom of steering jacket-to-instrument panel clamp and remove the two instrument panel to steering column clamp nuts Remove steering column assembly.

INSTALLATION: Reverse the removal procedure.

STEERING WHEEL & HORN BUTTON OR RING REMOVAL: *See "1952-54 Cadillac" (above).*

1953-54 CHEVROLET

CHEVROLET Steering Gear Removal: Remove steering wheel (see data below). Remove upper control shaft clamp bolt from shaft connector, disconnect horn wire at connector under instrument panel near point where wire comes from mast jacket. Remove mast jacket toe board grommet and seal from toe board Remove nuts and lockwashers from instrument panel-to-mast jacket clamp. (*CAUTION*—save all spacers located between bracket and support bracket on instrument panel—these must be re-installed), remove clamp. Remove two clutch head screws that attach gearshift control upper support to mast jacket. Pull upper control shaft and upper support up and out of engagement with shaft connector. Remove clamp bolt nuts and clamp retaining shifter housing to mast jacket, then rotate shifter housing with lower control shaft and control rods attached away from mast jacket Disconnect steering connecting rod at pitman arm (*CAUTION*—Carefully note relative position of steering connecting rod parts before disturbing them) Disconnect pump hoses at valve body unit (*CAUTION*—cap lines and ports to prevent spilling of oil or secure ends of hoses in raised position). Remove nuts, bolts and lockwashers attaching steering gear housing to steering support bracket. Remove left air duct, then rotate gear assembly to clear fender skirt. Raise gear assembly up and forward to remove from engine compartment.

Steering Wheel Removal—Pry out horn button or ornamental cap, remove steering wheel retaining nut. Remove wheel with Puller J-2927-A.

Installation—Install steering gear in car by reversing removal procedure (above) with particular attention to the following points:

Tightening Mounting Bolts—Install bolts, lockwashers, and nuts retaining housing to support brackets. Tighten mast jacket securely, then torque housing-to-bracket nuts to 27-40 ft. lbs.

Steering Wheel Installation—With steering gear on high point, install steering wheel with spokes horizontal Install washer and nut, torque to 35-40 ft.lbs.

1953 LINCOLN

LINCOLN Steering Gear Removal: Remove front seat cushion from vehicle. Remove steering wheel (see data below), disconnect steering column electrical connections. Remove accelerator from pushrod. Re-

CONTINUED ON NEXT PAGE

SAGINAW (G.M.) (Continued)

move bolt and clevis pin securing brake pedal, remove brake pedal. Remove carpeting from floor pan opening, then three screws securing column insulator to opening cover plates. Remove two screws securing upper floor pan opening cover to floor pan, remove cover. Remove seven screws securing lower floor pan opening cover, disconnect speedometer drive cable from instrument panel and pull through lower floor pan opening cover, remove cover. Remove two screws securing steering column support brackets to instrument panel, remove bracket. Remove clamp securing power brake reservoir hose to fire wall, then clamp securing hose to power brake fitting on power brake vacuum tank. Pull hose to engine side of floor pan opening cover to provide clearance. Remove cotter pins and release shift rod from steering column shift arm. Loosen clamp on lower steering column at steering gear housing, raise column sufficiently to disconnect wires at neutral switch. Remove steering column tube from steering shaft through inside of car. Disconnect hydraulic hoses at valve housing *(CAUTION*—Cap fittings and plug hoses to prevent oil leakage or place hoses in upward position). Raise front of car, remove nut securing pitman arm, remove arm using Tool 3590. **Loosen** three bolts securing steering gear assembly to frame *(CAUTION* —Remove shims, if any, then mark holes requiring shims to facilitate reassembly). With one man in car and another under car remove three bolts securing steering gear assembly. Remove assembly through passenger compartment.

Steering Wheel Removal—Remove cap and emblem assembly by grasping with hand and pulling outward from steering wheel hub. Remove steering shaft nut, then steering wheel using Tool 3600-D. If necessary to remove horn ring, remove three screws that hold horn ring securing plate to steering wheel. Remove horn ring securing plate, gasket and spring.

Installation: Install steering gear in car by reversing removal procedure (above) with particular attention to following points:

Tightening Mounting Bolts—With shims, if any, in place, install steering gear-to-frame attaching bolts loosely until steering column tube is rigidly in place. When tightened, torque to 30-35 ft. lbs.

Steering Wheel Installation—Clearance between wheel and tube flange should be approximately .12". Tighten steering wheel nut to 60-70 ft. lbs.

CAUTION—When installing horn ring spring make sure spring ends are properly seated in spring stops.

Oil Line Connections—Connect pressure hose (nearest engine) to fitting marked "PR" on valve housing assembly, secure return hose to fitting marked "RT" on valve housing assembly.

1954-55 LINCOLN

REMOVAL: *(NOTE*—On cars with power brakes, remove clamp securing reservoir hose to power brake fitting on vacuum cylinder, and remove clamp securing power brake reservoir hose to fire wall. Pull hose to engine side of floor pan opening cover to provide sufficient clearance). Remove front seat cushion. Remove steering wheel with tool No. 3600-D. Disconnect steering column electrical connections. Remove accelerator pedal from pushrod and remove brake pedal from pedal support bracket. Remove carpeting from floor pan opening. Disconnect speedometer drive cable from instrument panel and remove cover from floor pan opening. Remove support bracket from instrument panel. Disconnect shift rod from steering column shift arm. Loosen clamp on lower steering column at gear housing and raise column sufficiently to disconnect wires at neutral switch. Remove steering column tube from steering shaft through inside of car. Disconnect pressure and return hydraulic hoses at gear valve housing and place hoses in upward position to prevent leakage. Raise front of car and remove pitman arm using tool No. 3590. Disconnect steering gear assembly from frame side rail *(CAUTION—Remove shims, if any, located between mounting bolts and frame side rail. Mark bolt holes and number of shims required, and mark shims for identification with bolt holes).* With one man inside car and another under the car, remove the three bolts securing gear assembly to frame side rail and remove the unit through passenger compartment.

INSTALLATION: Replace steering gear in car and install loosely to frame side rail with the three attaching bolts (longest bolt to rear). Connect hydraulic hoses to valve assembly. Slide steering column tube on steering shaft with column clamp in place (do not tighten clamp). Secure column support to instrument panel bracket with two bolts and tighten finger tight. Tighten bolts securing gear housing to frame side rail *(CAUTION*—Replace shims, if any, in the exact position noted at time of removal). Complete the installation by reversing removal procedure making sure that steering wheel is in center position with wheels straight ahead before pitman arm is installed.

1952-55 OLDSMOBILE

OLDSMOBILE Steering Gear Removal: Disconnect battery, drain fluid reservoir on pump, disconnect hoses at gear and pump. Cover openings. Loosen mast jacket-to-steering gear housing clamp, remove steering wheel (see data below), install Tool J-5210 on end of worm shaft. Mask steering column for about 2" above instrument panel bracket. Loosen steering column in bracket, remove floor mat and floor pan plate attaching screws. Pull mast jacket up. Place 2" block between left front shock absorber arm and frame. Jack front end of car up at least 10", place car stand under frame. Remove left side filler plate and pitman arm from shaft. Remove starting motor and wire guide bracket, three steering gear-to-frame bolts. Remove steering gear by pulling it down and out of mast jacket carefully turning gear as it is removed so that all fittings and pipes clear frame and lower control arms.

Steering Wheel Removal—Disconnect horn wire at relay. On Standard wheel insert sharp instrument underneath edge of horn button and pry upward. Remove steering wheel nut, then horn contact assembly. On Deluxe wheel use small screwdriver to relieve spring tension on one end of spring clips holding horn button in place. Clips are accessible from underside of wheel. Remove steering wheel nut, contact plate and horn ring assembly. Using wheel puller, remove steering wheel.

Installation: Install steering gear in car by reversing removal procedure (above) with particular attention to the following points:

Tightening Mounting Bolts—Install three steering gear-to-frame bolts but do not tighten until mast jacket securely in place. When tightened, torque bolts to 35-40 ft. lbs.

Mast Jacket Location—Locate mast jacket to provide ¼-3/16" clearance between wheel and collar.

Oil Line Connections—Pressure Line "PR" farthest from engine, return line "RT" nearest engine.

1953-55 PONTIAC

REMOVAL: *(NOTE—If car is equipped with power brakes, remove power brake unit).* Hook front suspension in 5-passenger load position using tool J-5571 (front suspension hold down hook). Remove steering wheel using puller J-3044. Remove direction signal switch handle and gearshift lever and remove steering column to instrument panel bracket cap. Slide rubber grommet up column jacket. Roll back floor mat and remove pedal plates from floor. Remove neutral safety switch. Disconnect gearshift and selector rods, and direction signal wires. Disconnect oil lines at steering gear and secure lines high enough to prevent oil leakage. Raise car on hoist and remove starting motor, pitman arm, and left side tie rod end. Remove engine side apron on left side. Remove brake pedal hairpin spring retainer and slide pedal to right as far as it will go. If car is on a twin post hoist, it will be necessary to place stands under both front frame ends and lower front post approximately three feet to allow steering assembly to clear hoist. Push steering connecting linkage down and toward rear of car, remove steering assembly to frame attaching bolts, removing the upper bolt last, and lower assembly between lower control arm and steering connecting linkage *(CAUTION—Identify and retain any shims found between gear housing and frame as these must be returned to the same location for proper alignment of steering gear).*

INSTALLATION: Push steering connecting linkage down and toward rear and install steering gear assembly by guiding between lower control arm and connecting linkage. Remove hold down hook. Install front gear housing to frame bolt with lockwasher, finger tight *(CAUTION—Be sure to install shims in the same locations as removed from).* Install steering column lower bracket with lockwashers and bolts to upper bracket on instrument panel. Install two remaining gear housing to frame bolts, and tighten all three bolts. Check for correct shimming of steering gear housing to frame by seeing if steering column aligns with upper bracket when bracket bolts are loosened. If alignment is correct, tighten steering column bracket bolts *(NOTE—If* misalignment exists, it will be necessary to change housing to frame shims to correct alignment). Complete installation by reversing removal procedure.

STEERING WHEEL & HORN BUTTON OR RING REMOVAL: Remove deluxe horn ring button by turning counter-clockwise. Remove standard horn button by pressing down on one side, inserting screwdriver underneath opposite edge of button, and prying upward. Remove locknut, washer, horn ring, horn insulator and contact assembly. Remove steering wheel using puller J-3044. To install, reverse above procedure, making sure wheel is in straight ahead position (spokes horizontal and mark on steering shaft upward). Tighten

CONTINUED ON NEXT PAGE

SAGINAW (G.M.) C nt.

steering wheel nut to 25-30 ft. lbs. Tighten locknut finger tight plus 1/4 turn.

1953-55 STUDEBAKER

REMOVAL: Disconnect and remove battery (on coupe and hardtop, remove battery box). Remove steering post collar screws and slip collar up out of the way. Disconnect horn wire and on automatic transmission cars, disconnect quadrant light and starter cutout switch cables. Disconnect direction signal cables and shift lever rods. Loosen jacket clamp bolt at lower end of jacket. Remove steering wheel using puller J-5473, and remove jacket spring. Loosen jacket to instrument panel bracket clamp screw and remove jacket to instrument panel bracket screws and shims (if shims are used). Slip jacket off column. Remove the four steering post coupling nuts, separate coupling, keeping collector ring and insulators intact, and remove post assembly. Tape coupling studs to prevent damaging threads when removing the unit. On sedan and station wagon models, remove the left hand valve rocker arm cover. Disconnect tie rod from pitman arm and remove the pitman arm clamp bolt. Move fender gravel deflector out of the way and remove the three steering gear housing to mounting bracket bolts. On sedan models it may be necessary to shift the unit against the fender apron for clearance to remove pitman arm, then remove pitman arm. Disconnect hoses at pump and tape all openings. Shift unit rearward, inserting top end of unit through opening in firewall. Lift lower end of unit, turn it as necessary to gain clearance past fender apron and battery box, and lift unit out of car.

INSTALLATION: Reverse removal procedure and note the following: With gear in mid-position (high-spot) punch mark on end of worm shaft should be at top and "T" stamped on coupling should also be at top, with wheels in the straight ahead position.

STEERING WHEEL & HORN BUTTON OR RING REMOVAL:

Champi n & C mmander (Custom & Deluxe): Remove horn button assembly by pushing down on button and at same time turning button 1/3 of a turn. Remove wheel retainer and lockplate. Place puller center adapter in end of steering post and remove steering wheel with puller J-5473. To install, reverse removal procedure, tightening nut to 23-27 ft. lbs.

Champi n & C mmand r (Regal), President: Remove button from steering wheel by inserting knife blade under edge of button and forcing button up and out. Remove horn ring retaining screws and remove ring and rubber shock pad. Remove steering wheel retaining nut and lockplate. Place puller center adapter in end of steering post and remove steering wheel with puller J-5473. To install reverse removal procedure, tightening nut to 23-27 ft. lbs.

STEERING GEAR OVERHAUL

OVERHAUL: Ste ring G ar Disass mbly—Thoroughly clean steering gear (mast jacket removed). Place steering gear on holding fixture, then proceed to disassemble as follows:

1) Remove plugs (if hoses removed) from gear housing and attach hoses. Place ends of lines in container and drain gear as much as possible by turning steering wheel two or three times through full range. Remove oil lines between power cylinder and hydraulic control valve housing. Remove small bleed line between power cylinder and hydraulic control valve housing, then the two flexible hoses. (NOTE—Unless "O" ring seals are to be replaced, do not loosen swivel fittings, since they will aid when reassembling oil lines). Remove filler plug with vent.

2) Mark power rack cover and housing, then remove FOUR CORNER BOLTS from guide cover assembly (DO NOT REMOVE THE TWO CENTER BOLTS). Remove cover and guide assembly with all shims.

3) Mark side cover for ease when reassembling, then remove four side cover bolts. Then, tapping on end of pitman shaft with soft hammer, remove pitman shaft, side cover, and gasket as an assembly.

4) On Buick, measure from end of hydraulic valve cover to nearest edge of horn cable contact. On all cars except 1955 Cadillac, remove horn wire and contact from steering column. Turn steering gear to a horizontal position, mark control valve cover, control valve housing and gear housing to facilitate reassembly. Remove steering wheel, place special tool over threads of steering shaft to protect seal in valve cover when removing cover. On 1955 Cadillac, remove coupling flange-to-steering shaft dowel pin, supporting flange from below to prevent shock damage to thrust bearings. Remove flange from splined shaft. Remove felt washer.

5) Remove three valve cover attaching bolts. Carefully slide valve cover from steering shaft. Except on 1955 Cadillac, remove special tool from threads on steering shaft.

6) Mark power cylinder and housing for assembly purposes, then remove four power cylinder-to-housing attaching bolts. Remove power cylinder with gasket.

7) Straighten bent-over tangs on worm bearing adjusting nut lock. Use steering wheel on steering shaft to hold shaft and loosen worm bearing adjusting nut and lock. (NOTE—Deep chamfered side of nut is toward lock). Remove steering wheel, worm bearing adjusting nut and lock.

8) With steering gear still in horizontal position, carefully remove the control valve assembly from steering shaft, using care to keep spool, plungers and centering springs from falling out. *(CAUTION*—Do not lay control valve assembly where it is apt to pick up lint of dirt. Lay the control valve assembly on a piece of clean paper). Remove control valve lower thrust washer assembly from shaft (NOTE—Thrust washer assemblies are interchangeable). Place special tool on threads of steering shaft to protect worm bearing seal in housing, while removing shaft.

9) Remove three end cover attaching bolts and then remove end cover and gasket from housing. Carefully slide steering shaft and ball nut assembly through housing. Holding on to upper end of shaft, to take weight off worm bearing seal, will help to protect seal.

Individual Unit Disass mbly & R ass mbly—Proceed as follows:

Pitman Shaft & Sid C v r—*(NOTE—Lincoln adjusting screw endplay established at time of manufacture. Screw is fixed in end of pitman shaft and cannot b adjusted).* Turn adjusting screw down through side cover and remove side cover from pitman shaft. Remove adjusting screw and shim from slot in pitman shaft (except Lincoln). Clean all parts in suitable solvent. Inspect bushing in side cover for excessive wear. If damaged or worn excessively, replace side cover and bushing. Inspect pitman shaft sector teeth. If pitted, worn excessively or scored, or if pitman shaft serrations twisted, replace shaft. To reassemble (except Lincoln), check fit of pitman shaft adjusting screw shim in slot, in end of pitman shaft. With shim in place, screw head must be free to turn in slot, with no perceptible endplay to .002" loose. If endplay excessive, fit new shim (furnished in four thicknesses). Position adjusting screw, with selected shim, into slot in pitman shaft. (All Cars) Assemble side cover to shaft by turning adjusting screw counterclockwise until side cover seats firmly on housing. Start adjusting screw lock nut over threads of adjusting screw and leave finger tight.

Power Cylinder—Remove gasket and hold power cylinder in vise clamping power rack between brass jaws *(CAUTION—DO NOT place machined surfac s of rack in jaws).* Push power cylinder up to the rack and pull sharply away from rack to hammer adapter against piston (It may be necessary to repeat several times to break grip of rubber seals between adapter and cylinder). Remove safety nut, and piston with one spacer washer from each side of piston. Place Tool J-5293 (Lincoln 33568) over threads of piston rod to protect packing seal in adapter against damage. Remove adapter and large spacer washer from piston rod. (NOTE—Piston, rings, rod, pin and power rack are serviced separately. Adapter "O" Ring Seals are serviced separately or in kit with packing seal). Inspect power rack teeth for burrs, scores or excessive wear. Inspect power cylinder for scores. Inspect "O" ring seals and piston rings. Replace where necessary. Make sure that all parts are clean. Lubricate parts before reassembly. To reassemble, position large spacer washer over rod against power rack. With Tool J-5153 (Lincoln 33568) over threads on rod, install adapter. Install new "O" ring seals on adapter. Remove Tool J-5153 (Lincoln 33568). Install power piston (either side out) having one spacer washer on each side of piston, then install and tighten safety nut. Using ring compressor J-5186 (Lincoln 33569) to compress piston rings, install power cylinder over piston and adapter. It may be necessary to tap cylinder with soft mallet until flush with adapter flange.

Steering Shaft & Ball Nut—Remove clamp and ball return guides from ball nut. Remove sixty (60) steel balls, then carefully remove ball nut from shaft. Wash all parts in clean kerosene or other cleaning solvent. Inspect steering shaft for wear or brinelling in ball and needle bearing races (replace if worn or brinelled). Check shaft to make sure it is straight. Inspect teeth

C NTINUED N NEXT PAGE

SAGINAW (G.M.) C nt.

of ball nut and worm of steering shaft. If teeth pitted, worn or scored, replace part. Before reassembling be sure parts are absolutely clean and lubricated with clean engine oil. To reassemble, place steering shaft on bench with upper end to your right. Install ball nut on worm so that when teeth are facing up, deeper side of teeth are toward you. Install 21 or 22 steel balls in each circuit of the worm and ball nut. Install 8 or 9 steel balls in each guide. Holding halves of guide together to prevent the balls from falling out, push guides with balls over each circuit in ball nut. Install clamp and tighten in place. Run ball nut to upper and lower end of worm to check for freeness.

Valve Body–*(CAUTION–Spool and plungers are a very close fit in housing and must be removed and replaced carefully. They must be started carefully to avoid jamming and must not be forced into place).* Carefully remove spool, plungers and springs from valve body. Remove check valve *(CAUTION–Use care not to score or cut bore with screwdriver).* Inspect spool and plungers for scores, nicks, or burred edges. Test check valve by blowing through both ends. Ball should seat when blowing through small end, and allow air to pass when blowing through slotted end. Control valve body and spool are serviced as a unit. Plungers, springs and check valve are serviced separately. Replace damaged parts and make certain they are oiled before reassembly, so that spool and plungers slide freely in housing. To reassemble, install check valve in housing. Assemble spool into housing with counter-bored end up. Install compression springs and plungers.

Inspection & Reconditioning of Steering Gear Housing & Covers–Clean machined surfaces of housing of all gasket material. Inspect mating surfaces for burrs, and remove any burrs with flat stone. Inspect bushings and bearings for scored or worn condition, and replace if required. The following procedures cover the replacement of all bushings, bearings and seals in housing and covers. To replace, proceed as follows:

Steering Gear Housing Worm Bearing & Seal–On Lincoln, place Worm Bearing and Seal Remover Tool-3517 through steering gear end cover opening and drive the seal, washer and bearing from housing. On other cars, remove worm bearing seal by carefully tapping an "offset" screwdriver between seal and shoulder in housing, then pry lightly around seal to remove. Roller bearing is removed with a punch and should not be removed unless replacement is necessary, as removal will damage bearing. To install bearing, use Tool J-5189 (Lincoln Tool 3517-A). Bearing should rest on Shoulder in housing. (NOTE–Stamped end of bearing is against shoulder of installing tool, unstamped end enters housing first). On Lincoln, place washer on bearing so that when seal is installed washer will be between seal and bearing. On all cars, place new seal with lip (spring end) outward toward Bearing Seal installing Tool J-5189 ("Seal" end) (Lincoln 33560) and drive into steering gear housing to point where seal seats on shoulder of housing. *NOTE*–Lubricate feather edges of seal before installing.

Steering Gear Sector Shaft Bearing, Bushing & Seal–*(NOTE–Power Steering Gears on Lincoln Cars built after January 4, 1954 will not have steering gear sector shaft bearing. For those prior to above proceed as indicated below).* To replace bearing on Lincoln cars, turn shaft of Tool 3770-A counter-clockwise until jaws are flush with housing. Insert tool in steering gear housing and turn shaft clockwise until bearing is removed (NOTE–Be sure jaws of tool grip back of bearing). Inspect bearing for binds and freedom of movement. Lubricate bearing with M-4738 lubricant and place on Steering Gear Sector Shaft Bearing Installer Tool 3770, lettered end toward tool, and press carefully into steering gear housing. Recheck bearing for freedom of movement. To remove bushing and seal on Buick, Cadillac, Chevrolet, and Lincoln (On other cars, bushing and housing serviced as an assembly), support steering gear housing in an arbor press and press sector shaft bushing, seal (and retainer, if used) from housing using Tool J-1614 (Lincoln 3353.) Press new bushing into position using bushing driver J-1614 (Lincoln 3353 with adapter 3553-1). Soak new seal in oil, install in new packing retainer (if used) and press into housing (Lincoln use Tool 33587). On Lincoln, seal is installed with lip out. To replace packing or seal only, pry seal (and retainer, if used) out of housing. Soak new seal in engine oil, install in new retainer (if used) and press into housing.

Steering Gear End Cover Worm Bearing–Make sure bore in end cover is absolutely clean and that roller bearing is clean. Grip end cover lightly in vise. Insert Removing Tool J-5190 (Lincoln 33551) into bearing and turn screw, which will expand two plates under bearing and will then force tool and bearing out of cover. Use Installing Tool J-5191 (Lincoln 33551-A, Oldsmobile J-5255) to install new bearing. This tool has shoulder to locate bearing at proper depth. Place stamped end of bearing against shoulder of tool so that unstamped end enters bore first. Lubricate bearing with clean automatic transmission fluid.

Hydraulic Valve Cover Seal–Remove seal from valve cover by carefully inserting an "offset" screwdriver between seal and shoulder in cover, and prying lightly around seal. Place a new seal on Tool J-5188 (Lincoln 33562, Oldsmobile J-5254–large end) having spring side (lip side) to shoulder of installing tool. Drive new seal down to shoulder in cover. NOTE–Always lubricate feather edges of seal with clean automatic transmission fluid to facilitate breaking-in the new seal.

Steering Gear Reassembly: Be sure all parts are absolutely clean and lubricated with clean engine oil during reassembly. Proceed as follows:

Linc In–*(CAUTION–Before installing pitman shaft, tap s rrat d nd of shaft to assure no damage to s ctor housing nd seal.)* Install pitman shaft and cover assembly with new gasket, aligning side cover and steering gear housing marks .scribed. when disassembled. Secure with two capscrews and two Allen head screws. Loosen adjusting screw locknut. Turn sector shaft upper teeth (nearest side cover) as far as possible toward opening of the steering gear end cover. Turn steering shaft ball nut to top of ball nut race (nearest steering wheel end of shaft). Place Tool 33562-B on steering wheel end of shaft, and slide shaft through steering gear housing cover opening, holding up on shaft to take weight off seal while inserting. Insert first tooth of ball nut into first tooth showing on pitman shaft. Push lightly on ball nut end of steering shaft so as to turn teeth on pitman shaft, meshing them with teeth on ball nut. Install steering gear housing end cover and new gasket with two capscrews and two Allen head screws. (NOTE–If steering gear housing end cover fails to fit snugly against housing, turn shaft slowly to left and right to seat shaft in end cover bearing. DO NOT FORCE.) Install thrust bearing assembly with small race toward gear housing (Thrust bearing assemblies are interchangeable). Place new "O" ring seal in groove in face of housing. Turn holding fixture so that shaft is horizontal. Carefully install control control valve assembly with letter "B" marked on assembly toward housing. Turn steering gear to vertical position, move valve housing around to make sure thrust bearing balls are seated in race, then align marks on valve assembly and steering gear housing. Place Adapter Ring Tool 33577 over valve assembly and secure with three bolts. Center valve spool around worm shaft and tighten bolts evenly and securely. Install upper thrust bearing assembly with large race toward valve spool. Install new worm bearing tab lockwasher making sure inside lock tang slides freely in keyway of shaft, so lockwasher rests flat against upper thrust bearing race. Position locknut over shaft, having deeper chamfer toward tab lockwasher and start nut on threads just far enough so that it is left loose against face of tab lockwasher. Make worm bearing adjustment (see below).

Other Cars - **1)** Run ball nut to upper end of worm.

2) On 1955 Cadillac, replace felt washer, reinstall flange on splined shaft, replace coupling flange-to-steering shaft dowel pin.

3) On other cars, place gear housing in horizontal position. Place tool over threads of steering shaft to protect worm seal in housing. Slide shaft through housing, holding up on shaft to take weight off feather edge of seal while shaft is passing through seal.

4) On all cars, install end cover with gasket, tightening in place with bolts and lockwashers.

5) Install lower thrust bearing assembly with large race outward (toward spool). Carefully install control valve assembly (NOTE–Hydraulic connection bosses on control valve housing are identified with embossed letters. The side with identification should be facing up toward steering wheel). Turn steering gear to vertical position, move valve housing around to make sure thrust bearing balls are seated in race, then align chalk marks. Install Adapter Tool J-5182 with valve cover bolts and tighten bolts to 15-20 ft. lbs. torque. Install upper thrust bearing assembly

C NTINUED ON NEXT PAGE

SAGINAW (G.M.) Cont.

with large race toward valve spool. Install new worm bearing lock nut, and tanged washer (if used) making sure inside lock tang slides freely in keyway of shaft, so lock rests flat against upper race. Position locknut over shaft, having deep chamfer toward lock, and start nut on threads just far enough so it is left loose against face of lock (Nut must spin on threads freely without bind). Make worm bearing adjustment (see below).

Worm Thrust Bearing Adjustment—Temporarily install steering wheel (Studebaker Tool J-5563) after removing special tool from end of steering shaft (or tape from pitman shaft). Turn wheel counter-clockwise to extreme left (Chevrolet right) position so that valve centering plunger springs are fully compressed. Hold wheel in this position and tighten bearing locknut as follows:

▷*NOTE:* On 1955 Cadillac, when making this adjustment, use flange and suitable lever to hold shaft stationary.

Buick—Tighten nut just enough to seat thrust bearings against valve spool. Pull at rim required to rotate wheel in off-center range steadily should be 1/2-3/4 lb.

Cadillac—Tighten locknut to 30 ft. lbs. torque, then back off 1/4 turn. Pull at rim required to rotate wheel steadily in off-center range should be 3/8-3/4 lb.

Chevrolet—Tighten locknut firmly. Back off nut and retighten lightly. Pull at rim required to rotate wheel steadily in off-center range should be 1/4-1/2 lb.

Lincoln—Tighten locknut firmly, then back off nut and retighten lightly. Release wheel (make sure nut exerts pressure against spring-loaded plungers). Adjust to get pull at steering wheel rim of 1/4-5/8 lb.

Oldsmobile—Tighten nut just enough to seat thrust bearings against valve spool, then back off nut 1/16-3/32" measured at one corner of nut hex. Pull at rim required to rotate wheel steadily through off-center range should not exceed 3/8 lb.

Pontiac—Tighten locknut firmly, then back off nut and retighten lightly. Release wheel so that plunger spring pressure is against retaining collar J-5182. Thrust bearing nut should have no lash. Adjust to get pull at steering wheel rim of 1/4-1/2 lb.

Studebaker—Tighten locknut firmly. Turn shaft back to relieve pressure on springs, then, while holding shaft, back off nut until outer race of upper thrust bearing can be turned with a heavy drag.

On all car models, lock the nut by staking nut into shaft keyway (or bend lockwasher tangs against nut flat) using care not to disturb nut position. Remove Adapter Tool. Install new "O" ring seal in cover, use protective thimble on steering shaft to prevent damage to cover seals, install valve cover making certain that aligning marks are lined up, tighten cover screws with torque wrench as follows:

Buick, Pontiac—Securely.
Cadillac—25-29 ft. lbs.
Lincoln—17-22 ft. lbs.
Chevrolet, Oldsmobile, Studebaker - 15 - 20 ft. lbs.

NOTE—It is very important that all cover bolts be tightened as closely as possible to exactly the same torque.

Having completed worm thrust bearing adjustment proceed as follows:

Buick—Place adjusting screw and shim in slot of pitman shaft, install side cover with new gasket, and install lock nut finger tight on screw. Place gear assembly on left side, turn steering shaft until ball nut teeth are centered on pitman shaft bushings, and tilt nut slightly toward side cover opening. Hold pitman shaft with gear sectors straight down as it is installed in gear housing; use care to avoid damaging pitman shaft seal in gear housing as shaft is pushed through it. Install side cover and tighten bolts securely. Adjust pitman shaft as follows:

Buick Pitman Shaft High Point Adjustment—Install steering wheel and turn slowly through full range to check for free action, then turn wheel back to center position (2-3/4 turns) to center ball nut on central "high point" of pitman shaft sector. Turn pitman shaft adjusting screw clockwise until lash between ball nut and pitman shaft sector is just removed, tighten lock nut. Turn steering wheel two turns right or left from center. Pull at rim to rotate wheel in range where lash normally exists should be 1/2-3/4 lb. (1952-54), 1/2-7/8 (1955). Place wheel near center position, again check pull required to rotate wheel through "high point". This should be 1/2 - 3/4 lb. greater than pull in lash range. Turn adjusting screw as required to obtain this reading after locknut tightened. Record this reading for later use.

Cadillac, Chevrolet, Pontiac, Studebaker—Place gasket on cylinder and guide power rack through opening in gear housing with teeth on rack pointing toward center of housing. With scribe marks on cylinder and housing aligned, install cylinder-to-housing mounting bolts and tighten securely. Install pitman shaft and engage tapered teeth with ball nut and power rack as follows:

Cadillac—Be sure scribed marks on ball nut and power rack are aligned. Engage teeth of gear with power rack and ball nut.

Chevrolet—Turn steering wheel right or left until center groove of ball nut is in line with center of pitman shaft bushing. Position power rack so that center groove (third groove from piston end) is in line with center of pitman shaft bushing. Install pitman shaft so that center tooth in each set of sector gear teeth meshes with center grooves of ball nut and power rack.

Pontiac—Turn steering wheel clockwise to run ball nut to upper end of its travel. Install pitman shaft in housing with tapered teeth contacting ball nut, engage first tooth of gear with first tooth of power rack and worm gear ball nut.

Studebaker—Same as Chevrolet above.

Lincoln—Proceed with pitman shaft high point adjustment as follows:

Lincoln Pitman Shaft High Point Adjustment—Install steering wheel. Turn steering wheel slowly through full range to check for freedom of movement, then turn wheel back to midway position to center ball nut on central high point of pitman shaft. Turn steering shaft 45° right or left from center. Pull at rim of wheel required to rotate wheel smoothly over center high spot should be 3/4—1 5/8 lbs. Adjust pitman shaft adjusting screw to bring pull within this range. Difference between worm bearing preload (see Worm Bearing Adjustment above) and total preload must not be greater than 1 lb. on 9" radius. Record this reading for use in Power Rack Adjustment below. Tighten adjusting screw locknut to secure adjustment. Recheck adjustment after tightening locknut.

Buick & Lincoln—On Buick, turn steering shaft clockwise to limit of travel. On Lincoln, turn steering wheel until lower pitman shaft teeth are turned completely toward power cylinder opening. On both cars, position power cylinder assembly and new gasket with power rack all the way in cylinder. Align power cylinder and steering gear housing scribe marks. On Buick, mesh end tooth of rack between two end teeth in pitman shaft sector. On Lincoln, mesh first tooth on pitman shaft into first groove on power rack. Torque power cylinder attaching bolts securely (Lincoln 17-22 ft. lbs.)

Oldsmobile—Install steering wheel and turn it right or left until center groove in ball nut is in line with center of pitman shaft bushing. Place pitman shaft with cover and gasket into housing. *CAUTION—Teeth that engage ball nut are tapered.* Align center tooth of tapered sector with center groove of ball nut, tap side cover lightly until cover and gasket are flush against housing. Turn steering wheel clockwise all the way. Position power cylinder assembly, with marks aligned, into housing, engaging first tooth on rack into first groove (TOP GROOVE) on sector. Tighten power cylinder attaching bolts evenly and securely.

All Cars—Oil face of power rack and guide, then position power rack cover and guide assembly with all shims onto housing (CAUTION—Use care when holding shims in position to avoid any thin shims catching in bolt threads and face of housing). On Buick and Lincoln, install cover attaching bolts and tighten evenly and securely. On other cars, just start cover bolts with lockwashers through cover. These bolts must be left loose until Over-Center Adjustment has been checked and adjusted. See Over-Center Adjustment below.

Over-Center (Pitman Shaft-to-Ball Nut Lash—Cadillac, Chevrolet, Oldsmobile, Pontiac, Studebaker) Adjustment—With power rack cover bolts loose, turn steering wheel slowly through its full range to check for freedom of movement, then turn wheel back to midway position to center ball nut on central high point of pitman shaft. Turn steering wheel shaft 45° right or left of center. Place spring scale on spoke of wheel at rim and pull on scale, at a 90° angle to spoke, to turn steering wheel. Adjust pitman shaft adjusting screw so that pull on 9" radius to turn wheel smoothly over center high spot is:

CONTINUED ON NEXT PAGE

SAGINAW (G.M.) (C ntinu d)

Cadillac–1 1/8–1 3/4 lbs.
Chevrolet–1 1/8–1 1/2 lbs.
Oldsmobile–5/8 lb. greater than in lash range (1/2–1 1/4 lbs).
Pontiac–1–1 1/2 lbs.
Studebaker–1/2-1 lb.

Power Rack Guide (Pitman Shaft-to-Power Rack Lash–All Cars) Adjustment–Tighten power rack cover bolts evenly and securely. Turn steering wheel slowly through its full range to check for freedom of movement, then turn wheel back to center position. Turn steering wheel shaft 45° right or left of center. Place spring scale on spoke of wheel at rim and pull on scale, at a 90° angle to spoke, to turn steering wheel. If power rack cover shims have been selected properly there will be a preload in addition to over-center or pitman shaft adjustment when column shaft is rotated past center high spot as follows:
Buick–1/4-1/2 lb. increase or 1 1/4–2 1/4 lbs. total.
Cadillac–1/8-1/4 lb. increase or 1 1/4–2 lbs. total.
Chevrolet–1/8 lb. increase or 1 1/4–1 5/8 lbs. total.
Lincoln–1/32-3/16 lb. increase or 25/32–1 13/16 lbs. total.
Oldsmobile–No increase or 1–1 3/4 lbs. total.
Pontiac–No increase or 1/2-1 lb. total.
Studebaker–1/8 lb. increase or 1 1/4 lbs. maximum.
This completes the overhaul. Reinstall horn wire and contact where necessary. Install steering gear in car (See Removal & Installation above).

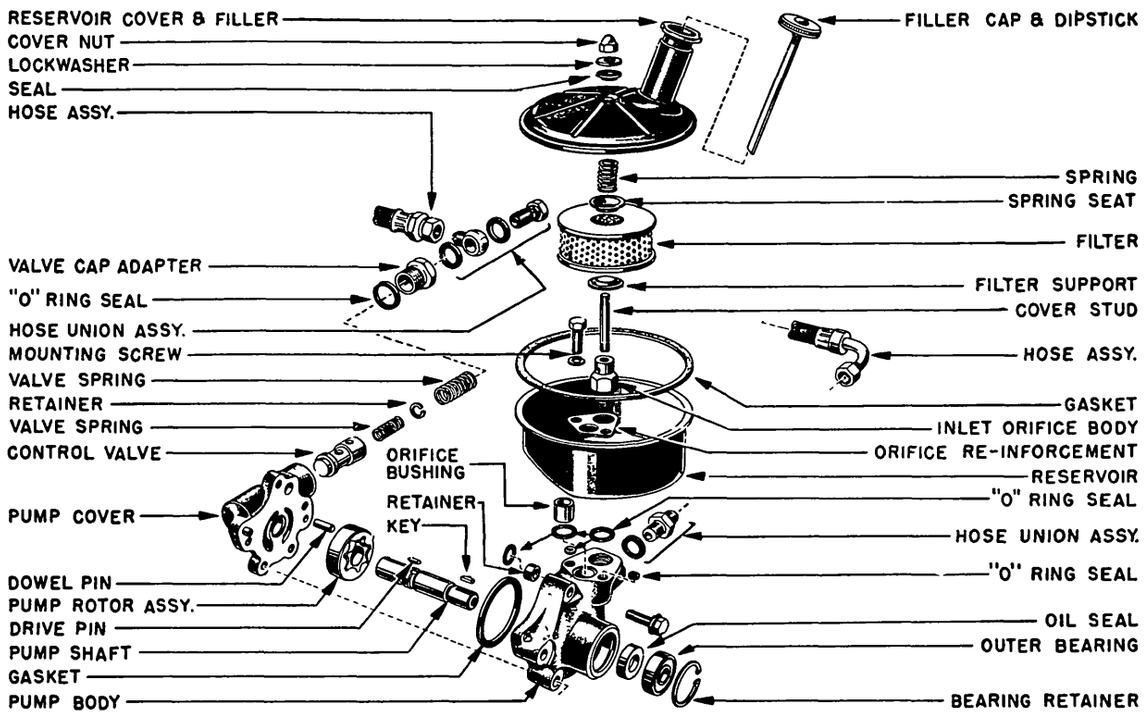
HYDRAULIC PUMP OVERHAUL

►***OIL PUMP CAUTION—Always cap or plug all pump ports whenever oil lines disconnected and use extreme care to keep dirt out of pump and to keep all pump parts clean.***

EATON OIL PUMP: Disassembly. Thoroughly clean exterior of pump before removing plugs or disassembling parts. Then proceed as follows:

1) Remove reservoir cover and gasket, then drain reservoir. Remove filters, reservoir, then separate pump cover from pump body. *(CAUTION*—Before removing cover place pump with shaft end down to prevent falling out of rollers).

2) Turn pump body over and slowly rotate shaft so that rotors fall free, remove rotors and drive key from shaft. Remove "O" ring seals from pump body.



3) Remove bearing snap ring from recess in body using snap ring pliers, tap lightly on end of shaft, remove shaft and bearing assembly from pump body. Remove inlet fitting and seal from pump body and valve cap adapter seal and orifice plate from cover, then remove flow control valve spring and damper by depressing relief valve slightly and removing snap ring with snap ring pliers.

4) Remove spring, relief valve and flow control valve from cover *(CAUTION*—Place parts where they will not be damaged).

Cleaning & Inspection: *CAUTION*—Do not wash shaft and bearing assembly in cleaning solvent which may wash lubricant out of sealed bearing (wipe bearing and shaft assembly with clean cloth only). Clean all other parts with clean kerosene or solvent, wipe dry with clean lint-free cloths. Inspect bearing in cover and replace if worn or noisy. Inspect shaft for wear and bearing for wear, roughness, or noisy operation (if either part requires replacement, press bearing off and on shaft in an arbor press). Inspect shaft seal in pump body for wear or damage (if seal requires replacement, drive old seal out with a punch, press new seal squarely into place with spring-loaded edge inward). Inspect valves for nicks, scores, or scratches and also inspect valve bores in pump cover (minor nicks may be removed by stoning). Check valve clearance in cover, valves should be free in bores and clearance must not exceed .0025". Inspect valve springs and replace if weak or distorted. Inspect cover and body for wear caused by rotors, replace if surfaces scored or worn. Inspect both rotors as detailed below and replace **both** rotors if either part worn or scored (rotors furnished as matched sets).

Inner & Outer Rotor Clearance—With one tooth of inner rotor fully meshed in outer rotor, measure clearance between rotors at opposite inner rotor tooth using a feeler gauge. Repeat this check for each rotor tooth. Replace rotors if clearance exceeds .006" (Packard), .008" (Others).

Outer Rotor Clearance in Pump Body—Insert outer rotor in pump body, check clearance between outer diameter and bushing in body with feeler gauge. Replace pump body if clearance exceeds .006" (Kaiser), .008" (Others).

EATON "ROTOR TYPE" HYDRAULIC PUMP

Rotor Side Clearance—Install both rotors in pump body, place straightedge across face of pump, use feeler gauge to measure clearance between rotors and straightedge. Replace pump body if clearance exceeds .0025".

Spring Tension (Relief Valve) 32 lbs. at 1.18".

Spring Tension (Flow Control Valv)—16 lbs. pull plus or minus 1½ lbs. at 1.20".

Reassembly—If removed, install new oil seal in pump body bore with lip toward rotors. If ball bearing removed from pump new bearing should be pressed on with arbor press until it butts against shoulder on pump shaft. Using all NEW seals and gaskets and lubricating all moving parts with Automatic Transmission Fluid Type A, proceed as follows:

1) Install assembly of pump shaft and bearing in pump body bore. Install ball bearing retainer. Position drive pin or key in pump shaft slot.

2) Install rotor assembly. If valve subassembly disassembled, install relief valve spring, relief valve, and retaining ring in flow control valve body. Compress assembly into body until there is sufficient room for installing ring in valve body groove, install retaining ring.

3) Install orifice plate in pump body bore. Install flow control valve spring. Install new gasket on hose adaptor valve cap, install and tighten cap. Install new gasket at pump body pressure port and a pump body-to-cover gasket.

CONTINUED N NEXT PAGE

HYDRAULIC PUMPS (Cont.)

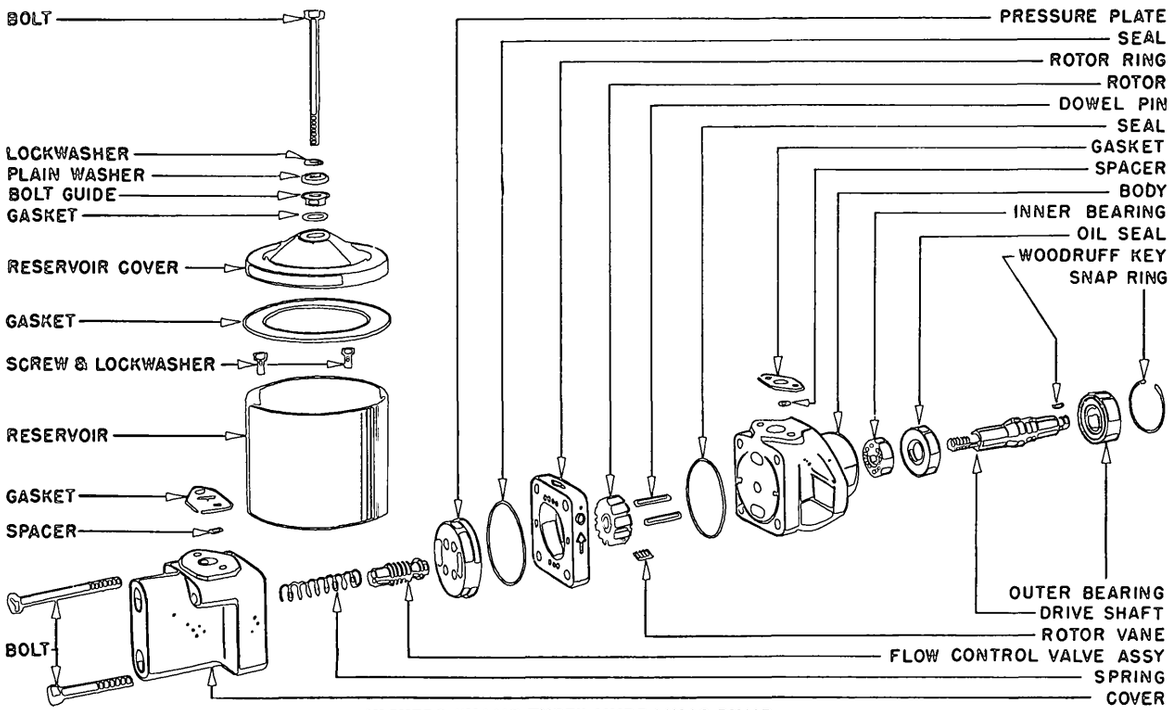
4) Install pump cover on pump body. Install screws and torque tighten to 30-35 ft. lbs. (Nash & Packard 25-30 ft. lbs.) Install new "O" ring gaskets on top of pump body, install reservoir and filter.

VICKERS OIL PUMP: Disassembly. Thoroughly clean exterior of pump before removing plugs or disassembling parts. Then proceed as follows:

1) Remove reservoir cover and gasket, then drain reservoir. Remove four reservoir-to-pump mounting screws, then remove reservoir, gaskets, and spacers. Remove pump cover-to-body attaching bolts, then cover assembly with control valve assembly and spring. Discard cover "O" ring seal.

2) Remove pressure and return line unions with "O" rings from pump cover, discard "O" rings. Push spring retainer plug (between pressure and return line unions in cover) inward to remove. Discard "O" ring seal, remove plug snap ring. *NOTE—It is not necessary to remove plug, "O" ring and snap ring to service remainder of pump. Remove only if evidence of leakage at this point.*

3) To disassemble control valve assembly, remove end screws with spacers, relief ball, relief spring guide and relief spring.



4) Lift pressure plate off dowel pins which extend through pump ring, remove pump ring from dowel pins in body. Remove rotor with vanes from body, discard "O" ring from groove in pump body. Remove bearing retainer snap ring from front face of pump body.

5) Remove drive shaft and outer bearing assembly from pump body, press outer bearing off drive shaft over threaded end of shaft, after removing woodruff key from shaft.

6) Using punch, tap drive shaft seal and inner bearing from pump body *(CAUTION—*Seal must be removed first to permit removal of bearing).

▷*HANDLING CAUTION—Use care when handling pump body especially when removing drive shaft and inner bearing with seal to prevent marring or scarring finished surface which mates with cam ring on reassembly of pump.*

Cleaning & Inspection: *CAUTION—*Do not wash large sealed bearing in cleaning solvent which may wash lubricant out of bearing (wipe bearing and shaft assembly with clean cloth only). Clean all other parts with clean kerosene or solvent, wipe dry with clean lint-free cloths. Inspect both bearings for wear or roughness, inspect shaft for wear. Check fit of pump vanes in rotor slots (vanes should be snug but must slide freely in slots), replace rotor if vanes excessively loose, replace vanes if worn or scored. Inspect all ground surfaces of cam ring for roughness or wear (slight irregularities can be stoned out), replace ring if inner cam surface scored or worn. Inspect flat surfaces of pressure plate and body for wear or scoring (faces may be trued up by lapping until smooth and flat) *CAUTION—*all traces of lapping compound must be cleaned out. Inspect relief valve poppet and flow control valve plunger for wear or scoring paying particular attention to seating surfaces. Clean out all passages in pump cover and body.

VICKERS "VANE TYPE" HYDRAULIC PUMP

Reassembly: Use all NEW seals and gaskets. Lubricate all moving parts with clean engine oil and install parts in reverse order of disassembly procedure (above) with particular attention to the following points:

Shaft Seal Installation—After the inner ball bearing is installed in pump body, install seal with the two 1/16" holes in casing toward outside and use a tube or shaft 1 3/4" in diameter to apply pressure on outer edge of seal to seat it in body.

Bearing Installation—Large sealed bearing should be installed with stamped face of inner race toward threaded end of shaft, small bearing with stamped face of inner race toward splined end of shaft. Press on inner race only when installing bearings.

Cam Ring Installation Caution—Install ring with marks made during disassembly lined up and make certain that arrows on ring point in direction of pump rotation (clockwise viewed from front or shaft end of pump).

Rotor & Vane Installation—Install vanes with rounded (radius edge) outward toward cam ring.

Relief Valve Assembly Installation—Make certain that all of the original shim washers are re-installed in the valve plug (these shims control oil pressure). If any of the relief valve parts are replaced, valve operation must be tested and adjusted after pump installed on car as follows:

Relief Valve Testing & Adjustment—Use Gauge J-5176 to check pump pressure. See Testing Hydraulic Oil Pressure (above). Relief valve should start to open (will be indicated by slight buzzing noise in pump) at pressure of 700 lbs. or slightly higher and maximum pump pressure should not exceed 900 lbs. with engine speed increased above idle. If pressure not correct, adjust number of shims in relief valve plug for correct performance (add shims to increase pressure, remove shims to lower pressure).

Final Assembly Test—After assembly completed, rotate pump shaft by hand and make certain pump has free movement. Plug or cap all hose connections to keep dirt out of pump until lines connected.

STUDEBAKER MECHANICAL TYPE

Studebaker, Comm. & Land Cruiser 4H (1953) Optl.

►*SAGINAW (G.M.) POWER STEERING used on later cars.*

DESCRIPTION: The mechanical power steering unit consists of a belt driven shaft and pulley assembly rotating two multiple disc clutches in opposite directions through a drum and pinion gear assembly. A clutch activating hub and plate controlled by the steering shaft activates either of the multiple disc clutches for directional power control. The steering gear shaft is direct acting upon the steering gear unit and steering is not affected in the event of power failure. With power off, a ratcheting sound will be heard when the steering wheel is rotated. This sound is normal and will disappear when power is applied. The driven pulley and bearing assembly is mounted in a spring loaded bracket, and a power load in excess of the pre-determined amount will cause the spring to depress and allow the belt to slip, preventing undue strain on the steering gear.

ADJUSTMENTS: Proceed as follows:

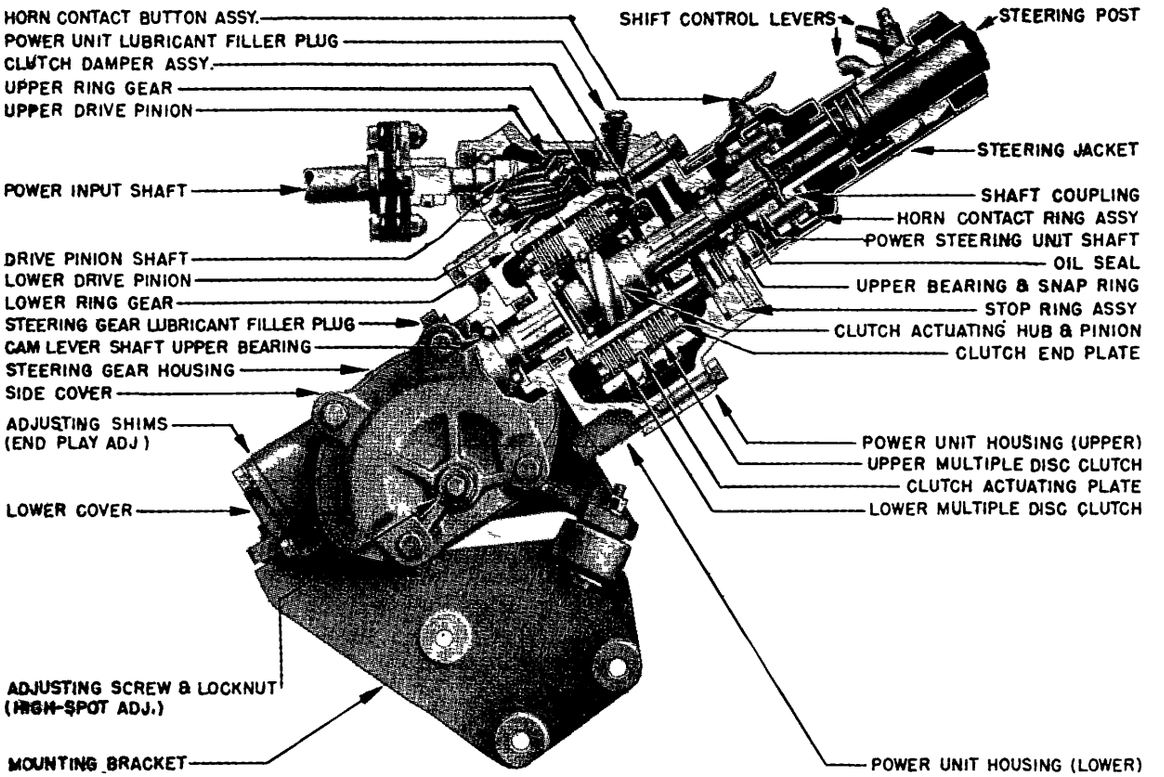
ADJUSTMENT NOTE—No adjustment of Power Steering Unit required in service other than Belt Adjustment (see below).

Belt Adjustment: Loosen capscrew at the adjusting arm and raise drive pulley and bearing assembly until the plain washer under the castellated nut is just loose and free, then tighten adjusting arm capscrew.

Steering Gear: *CAUTION—Make adjustments with load removed from front wheels (pitman arm disconnected or front wheels free of the floor with front end supported at outer ends of lower control arms). Adjust in following order:*

End Play Adjustment—*Disconnect and remove Power Steering Unit (see Removal data below).* Loosen locknut and back off Cam Lever Shaft Adjusting Screw (on side cover) to provide clearance and remove any cam lever shaft drag. Install tool J-5486 on steering gear, hook spring scale (scale must be calibrated in ounces) to hole in arm of tool. Measure pull required to turn steering gear shaft *(CAUTION* —pull must be at right angles to tool or tangent to turning circle). Shaft should turn smoothly with steady pull of 10-18 ounces. If pull not within limits, adjust by loosening steering post jacket clamp, removing lower cover screws, and adding or removing shims located between lower cover and housing until correct pull secured *(CAUTION*—lower cover screws must be tight when checking this turning pull). Then adjust High Spot (following).

High Spot Adjustment—*Not necessary to remove Power Steering Unit but engine must be idling at normal operating temperature.* Place steering wheel in center position (midway between end positions) with front wheels straight ahead. Loosen locknut on adjusting screw on side cover, turn adjusting screw in until all play removed, then back screw off, finally turn screw in until it just contacts the lever shaft. Turn steering wheel back-and-forth over the center of travel or high spot of the steering gear cam and turn the adjusting screw in until a slight drag is felt, then tighten adjusting screw locknut being careful not to change the adjusting screw position. Check adjustment by hooking spring scale (scale must be calibrated in ounces) to rim of steering wheel and measure pull required to rotate wheel through center high spot. Scale heading should be 16-24 ounces. Readjust adjusting screw, as required, to secure this pull. Recheck pull after adjusting screw locknut tightened.



NOTE—With steering wheel in center high spot position, **left** front wheel should be in straight-ahead position. Correct as necessary by adjusting **left hand tie rod.** Then set toe-in by adjusting **right hand tie rod only.**

LUBRICATION: *CAUTION— Power Steering Unit and Steering Gear are lubricated separately with DIFFERENT lubricants as follows:*

Power Steering Unit: Use only Studebaker Steering Power Unit Fluid AC-2407. Check level every 1000 miles, drain and refill every 10,000 miles. Maintain level even with inspection plug on left or right side of housing, add fluid through filler plug opening on top of housing.

►*LUBRICATION NOTE—If Studebaker Fluid AC-2407 not available, good quality SAE 10W ngine oil may be used. Unit may be noisy if engine oil used and regular AC-2407 Fluid should be installed at first opportunity.*

Steering Gear: Check at 5000 mile intervals. Maintain level at filler plug hole on top of case. Use only approved steering gear lubricant.

STUDEBAKER MECHANICAL TYPE POWER STEERING GEAR

REMOVAL & INSTALLATION:

Removal: 1) Remove steering wheel.

2) Disconnect battery cable and remove battery.

3) Disconnect quadrant light cable and starter cut-out switch cable (cars with Automatic Trans.), disconnect horn wire at terminal on steering jacket.

4) Disconnect shift lever rods from steering column levers, loosen jacket clamp bolt.

5) Loosen jacket bracket-to-instrument panel capscrew, slip steering jacket up on steering post as an assembly to proper clearance for steering unit removal.

6) Remove four nuts from bolts attaching steering post collar-to-collar on power steering units shaft *(CAUTION*—Do not re-use elastic stop nuts—use new nuts when re-installing power unit). Slide steering post, rubber insulator, and metal plate out of the way (plate and collar cannot be removed without removing jacket from steering post).

7) Disconnect horn wire from collector ring, then remove upper rubber insulator, horn collector ring, and lower rubber insulator.

8) Disconnect power input shaft by taking out two bolts in coupling at power steering unit end of shaft, position shaft out of the way.

CONTINUED ON NEXT PAGE

STUDEBAKER MECHANICAL (CONTINUED)

9) Take out four capscrews attaching power steering unit to steering gear housing, remove power steering unit from beneath car. Remove intermediate drive shaft hub from pinion drive shaft.

Installation: Reverse the removal procedure given above.

OVERHAUL: Thoroughly clean outside of Power Steering Unit, then proceed as follows:

1) Using an awl or similar sharp pointed tool, pry out drive shaft oil seal, remove power input shaft snap ring with small screwdriver, slip power input shaft and ratchet assembly from housing as a unit.

2) Remove the three capscrews which join the two sections of the housing. Use a suitable drift to drive out taper pin. Using awl or similar sharp pointed tool, remove oil seal. Then, with small screwdriver, remove snap ring from steering column main shaft.

3) Separate upper housing from lower housing. When pulling housings apart, be careful not to drop pinion gears and needle bearings (each pinion assembly consists of a pinion gear, gear shaft, pinion bearing spacers, and 19 needle bearings). Slip clutch assembly, mainshaft, and upper ring gear as an assembly from the housing, lift upper ring gear off the assembly, remove housing gasket and discard.

4) Place main shaft and clutch in a vise equipped with copper jaws. Remove damper hub retaining snap ring. Lift damper hub from assembly, then remove clutch lock plate and screw. Unscrew clutch end plate, remove from assembly.

5) Lift off clutch discs and clutch friction plates as an assembly (5 clutch discs, 5 clutch friction plates), slip ring gear thrust washer from clutch actuating plate.

6) Remove damper hub lower retaining snap ring from main shaft, then with screwdriver remove outer ball race snap ring, lift outer ball race from main shaft, remove ball bearing.

7) Holding clutch actuating plate with one hand and grasping main shaft, lift parts out of clutch hub as a unit. ***Do not allow shaft or plate to turn as this will permit steel balls to fall out of grooves of the two parts*** (six balls used in assembly). Holding assembly over a bench to prevent losing balls as units are separated, turn shaft out of actuating plate.

8) Remove the ball bearing, lower clutch discs and friction plates assembly. If it is necessary to remove lower assembly end plate, count number of turns so it can be assembled in like manner. Method of removal is same as for upper plate.

9) Remove 4 cap screws from upper housing retainer. Turn housing over and with suitable drift drive out upper retainer. To remove sealing ring around retainer, pick ring out of groove and remove ring from retainer.

10) If it is necessary to remove the ball bearing, first remove upper retainer bearing snap ring, then slip bearing out of upper retainer, lift stop ring assembly out of housing.

Inspection: Inspect all parts for damage or wear, repair or replace where necessary.

Reassembly: 1) Install stop ring assembly in housing. Turn stop plate against one of stops, install new sealing ring in upper retainer, install upper retainer. Install four cap screws, tighten securely.

2) With clutch hub in vise install lower clutch assembly. Reoil clutch assembly if cleaned for any reason. Install clutch disc (driven) first and alternate with clutch friction plate (drive).

3) Install lower ball bearing with ball cage to top, slip clutch actuating plate over clutch hub, grease steel balls in place on plate. Insert steering column mainshaft, turn shaft clockwise just enough to locate balls on worm. Turn shaft counter-clockwise start balls on worm.

4) Install ball bearing with ball cage against top shoulder of worm, slip outer ball race over shaft and place it over the bearing being sure it is seated properly, install outer ball race snap ring, slip ring gear thrust washer over clutch hub.

5) Install upper clutch assembly, first installing a clutch friction plate and alternating with a clutch disc.

6) Screw end plate in place, tighten finger tight. Slip damper hub and retainer assembly on steering column main shaft. Install snap ring, then place collar of power steering unit shaft (steering post end) over main shaft. With normal amount of effort turn shaft until a definite stop is felt. Mark on damper hub should now line up with edge of clutch hub. Turning shaft in a clockwise direction will lock upper set of clutches. Lower set can now be turned freely. Turn adjusting collar in opposite direction until mark on damper hub lines up with edge of clutch hub. This locks lower set of clutches. Upper set of clutches can now be turned freely.

7) If either set of clutches do not lock by lining up mark on damper hub with end of clutch hub it will be necessary to loosen or tighten clutch end plate and repeat adjustment for both upper and lower sets of clutches.

8) Install end plate lock, install snap ring, align clutch discs.

9) Install ring gear into lower housing, being sure wide shoulder is to bottom of housing. Install pinion shaft (before installing push pin to one side). Slip pinion bearing spacer over pinion shaft, install lower pinion gear, insert needle bearings in place, slip pinion bearing spacer over end of pinion gear shaft. Install upper pinion in same manner as described for lower pinion.

10) With clutch assembly held securely in place, align clutch friction plates, then install into the lower housing meshing clutch friction plates with ring gear.

11) Place new gasket in position on housing, slip upper ring gear in place, slip upper housing into place over main shaft and clutch assembly. Install retaining snap ring. Install three retaining cap screws, tighten snugly. Install taper pin, tighten cap screws securely. Slip power input and ratchet assembly into housing as a unit. Install snap ring and new oil seals. Turn steering column shaft from against stop to center position before installing unit in car.

GEMMER WORM & ROLLER

Willys, Pass Cars②

①—Different steering gear used on 1949 51 models See "1949-51 Ford Pass Car Worm & Roller"
②—Ross Cam & Twin Lever also used

►CHANGES, CAUTIONS, CORRECTIONS

►*WILLYS STEERING KNUCKLE ARM INSTALLATION CAUTION* Ross & Gemmer steering gears used on Passenger Cars require different steering knuckle arms (not interchangeable)

►*1955 FORD STEERING LINKAGE ALIGNMENT CAUTION (Victoria & Sunliner)* An 11/32" spacer is used between steering column bracket and instrument panel If spacer omitted binding or hard steering condition may result due to misalignment

►*1955 FORD PASS CAR & COURIER STEERING WHEEL ATTACHING NUT INSTALLATION CAUTION* Nut should be torqued to 40-60 ft lbs and staked once with prick punch to prevent nut from loosening

►*1955 FORD PASS CAR SECTOR SHAFT BEARING PRODUCTION CHANGE* Since approximately June 27 1955 a spacer (AD 3567-A) has been used in production to assure correct positioning of sector shaft bearings and should be installed on earlier production units whenever it becomes necessary to replace the bearings Install spacer between the two bearings on the sector shaft Bearings should be installed with Tool T52L 3576 AAD

►*1955 FORD F-100, 250 TRUCK DRAG LINK INSTALLATION CAUTION* It is possible to install drag link in reversed position When properly installed offset end of drag link is attached to sector shaft arm and the lubrication fittings will be on the bottom side of the link

►*1952 53 LINCOLN & MERCURY CONTINUOUS BLOWING OF HORN OR FAILURE TO BLOW CORRECTION (Due to Steering Column Movement)* An improperly tightened lower steering column tube clamp may cause the above condition To properly set horn ring air gap proceed as follows Remove steering wheel assembly check horn wire contact ring in tube to make sure it is properly seated Replace steering wheel Loosen steering column bracket-to-dash screws and clamp at lower end of column Depress one horn ring spoke 3/16 1/4" below steering wheel spoke and slide steering column tube so horn will blow at this setting Tighten column bracket-to-dash screws to 12-15 ft lbs Check setting at opposite ring spoke required to blow horn (3/16"-1/4") Torque 3/8" clamp screw at lower end of steering column to 30-35 ft lbs (45-50 ft lbs if 7/16" bolt installed with improved clamp) Improved clamps are FDD-3507-A (Lincoln with Power Steering), FDD-3507-B (Lincoln with Std Steering) FDC-3507-A (Mercury)

►*1954 (& EARLIER)–1955 NASH AMBASSADOR & STATESMAN DIRECTION SIGNAL SWITCH & CAM INSTALLATION CAUTION* 1954 & Earlier Switch Part No 3131527 and Cam Part No 3113966 (including Cam Springs Part No 3130161) should be pressed onto steering column tube 3¼" ±1/16" to Serial No R664004 (Ambassador) K530456(Statesman) and 3 7/16+1/16" after above numbers Insert two 1/8" cotter pins through cam spring loops With pliers compress springs several times to the limit permitted by diameter of cotter pins Remove cotter pins Apply lubriplate to springs and openings On 1955 models using Switch Part No 3144224 and Cam Part No 3144225 cam should be pressed onto steering column 3 7/32"±1/16"

►*1954 NASH STATESMAN & AMBASSADOR OVERDRIVE KICKDOWN SWITCH "SQUEAK" CORRECTION* Coat embossed end of Kickdown Switch Contact Bar with solder

►*1954 RAMBLER INTERMITTENT OR LACK OF HORN OPERATION CORRECTION* May be due to poor ground circuit between horn button retaining contact plate and chassis through steering worm tube To correct remove horn button cap and spring Strip 2" of No 14 wire of insulation and twist strands together Loosen one of Phillips head screws which hold lower spring retainer to wheel hub Loop one end of bared wire under Phillips head screw and tighten it in place Loosen steering wheel nut and loop other end of bared wire beneath it Tighten steering wheel nut securely

►*1954 RAMBLER STEERING LINKAGE PRODUCTION CHANGE (To Eliminate Interference)* Pitman Arm Part No 3138741 and Idler Arm Part No 3116777 became effective in production beginning Serial No D 179973

DESCRIPTION Consists of "hour glass" type worm mounted on steering shaft and carried on roller bearings at top and bottom Chrysler & DeSoto models are of "straddle" design with added bushing at adjusting screw end of shaft within side cover

ADJUSTMENT. Before making adjustments, align steering gear as follows Loosen gear-to-frame bracket bolts (on some models, also loosen dash bracket bolts) Allow gear to align itself, then tighten gear-to-frame bolts If necessary, shim dash bracket, or elongate mounting holes so column will not be sprung when bracket bolts are tightened

Worm Bearing Adjustment (In Car): Chrysler, DeSoto, Dodge, Plymouth–If excessive endplay exists, remove steering gear pitman arms, drain housing, and disconnect horn wire at connector between steering gear and horn Remove capscrews holding grease retainer cover at bottom of housing Remove shims of sufficient thickness to eliminate endplay in worm, but not enough to cause binding when cover is bolted tightly in place Turn steering wheel from extreme right to left If any stiffness exists, too many shims have been removed

Ford (Pass.), Lincoln & Mercury–Disconnect sector shaft from steering arm to idler arm rod Turn steering wheel two complete turns from straight ahead position (spokes in a horizontal position) with steering gear arm pointing directly forward) Hook a spring scale to steering wheel spoke at wheel rim and rotate wheel at least one complete turn noting the pull required to keep wheel moving which should be 1/8 to 5/8 lb If necessary to adjust, add or remove shims as follows Remove screws securing steering gear housing upper cap to housing and work cap and column jacket upward to allow clearance (if additional working clearance required, remove steering wheel) To add a shim split shim at one point then install the shim with the split in the upward position (make sure that split ends do not overlap To remove shims, separate shims from shim pack with a knife blade, passing knife blade all the way around shim pack being careful not to damage shim pack Remove one shim at a time, checking bearing preload after each variation in shim pack *NOTE*–Steering column and housing upper cap must be assembled on steering gear housing each time preload is checked

Ford Trucks–Align steering gear assembly as indicated above Reposition column tube if necessary so that 1/16" clearance exists between upper edge of steering column tube and shoulder of steering wheel Disconnect pitman arm from sector shaft and loosen locknut on sector shaft adjusting screw Turn adjusting screw counter-clockwise to remove load from worm Turn steering wheel in one direction to limit of its travel, and using a scale, measure pull required at rim of wheel to keep the wheel rotating The pull required should be ¼ ¾ lb (F-1 2 3 100 250 350 ½ & ¾ Ton Trucks) ½-1 lb (Other Trucks) Adjust preload by adding or removing shims from underneath steering gear housing end plate

Frazer, Henry J, Kaiser–Disconnect tie rod from pitman arm Turn steering wheel to extreme right or left then back off about 1/8 turn With spring scale attached to spoke of wheel at rim pull required to turn wheel should be ½-1 lb (1947-48 Models) ¼ ¾ lb (1949 & Later Models) To adjust remove housing end cover drain lubricant from housing and add or remove shims between housing and cover as necessary

Hudson, Nash, Rambler, & Willys–Turn steering wheel about one turn from straight ahead position and secure wheel to prevent movement Shake front wheel sideways noting any end movement that may be felt between steering hub and jacket tube *(CAUTION*–Be careful that movement noted is not caused by steering jacket tube bearing) Adjust endplay by loosening the four cover capscrews about 1/8" Add or remove shims as necessary *(NOTE*–Remove shims by separating with a knife being careful not to damage shim pack Shims can be added by splitting shims and inserting in place with split toward the top)

Packard–Remove pitman arm from cross shaft Turn steering wheel to extreme right or left and back up 1/8 turn With spring scale attached to spoke of wheel

CONTINUED ON NEXT PAGE

GEMMER WORM & ROLLER (Continued)

at rim, pull required to turn wheel should not be less than ½ lb. or more than 1 lb. Add or remove shims in same manner as for Hudson, Nash, Rambler (above).

Worm & Roller Mesh Adjustment (In Car): Chrysler, DeSoto, Dodge, Plymouth—Remove pitman arm from shaft and install another arm for use during adjustments. Turn steering wheel to mid-position (high spot). Check movement of steering pitman arm back and forth to determine amount of backlash. If any backlash exists, adjust as follows: Remove roller tooth shaft adjusting screw locknut and slide lock plate off far enough to clear lock boss on roller tooth shaft cover. Tighten roller tooth shaft adjusting screw enough to eliminate freeplay between roller tooth shaft and worm, *but it must not bind.* Slide lock plate in position against roller tooth shaft cover and lock it. Install and tighten adjustment screw locknut. Check steering gear operation and adjust if necessary.

Ford Pass. Car, Ford Truck, Lincoln & Mercury—On Passenger Cars, disconnect sector shaft arm from steering arm to idler arm rod. On Truck Models, disconnect steering sector arm (pitman arm) from the sector shaft. Attach a spring scale to steering wheel rim and pull the wheel through the "high spot" (straight ahead position), and note reading on scale.

Ford Pass. Cars—Reading should be at least ½ lb. above worm bearing preload, but total reading must not exceed 1 5/8 lbs. To adjust, remove adjusting screw cover and locknut. Rotate adjusting screw clockwise while moving steering gear arm back and forth until all backlash has been removed.

Ford Trucks—Reading should be 1-2 lbs. (F-1, 2, 3, 100, 250, 350, 1/2 & 3/4 Ton) 1 1/2-2 1/2 lbs. (Others). To adjust, remove adjusting screw cover and locknut. Center steering wheel, turn adjusting screw in a clockwise direction until all endplay is removed from sector shaft.

Lincoln & Mercury—Reading should be 1-1 5/8 lbs. To adjust, turn sector shaft adjusting screw in if reading is less than 1 lb., loosen screw if reading is greater than 1 5/8 lb.

Frazer, Henry J, Kaiser—With pitman arm disconnected, place steering wheel in centered position. Turn wheel approximately 30° either way from centered position. With spring scale attached to spoke at rim, pull required to pull wheel through centered position should be 1½-2½ lbs. (1947-48 Models), ¼-¾ lb. (1949 & Later Models). To adjust, tighten adjusting screw down snug, turning it clockwise, then back off adjusting screw not more than 1/8 turn. Install lock plate and nut on adjusting screw.

Hudson, Nash, Rambler & Willys—With pitman arm disconnected place steering wheel in center position ("high spot"). If steering wheel removed, the wide flute on upper end of worm tube should be centered at the bottom. Shake pitman arm sideways to determine amount of clearance between worm and cross shaft roller. A movement in excess of 1/32" indicates adjustment required. Remove locking cap from external adjusting screw and remove star washer. Tighten the external screw, but do not overtighten, until sideplay is less than 1/32". Install star washer and locking cap.

Packard—With pitman arm removed from cross shaft and steering wheel in straight ahead position (on "high spot"), attach scale to rim of steering wheel and note pull required to move steering wheel through the "high spot". The pull should be ¾ lb., greater than that of worm bearing preload (see above), but not more than 2 lbs. To adjust, place steering wheel on the "high spot" and remove cross shaft adjusting screw locknut. Raise lockplate enough to clear jaws on cross shaft cover and turn adjusting screw until effort required to pull steering wheel through "high spot" is 1½ to 2 lbs. Install locknut and tighten.

STEERING WHEEL POSITION: With steering at mid-point (roller on high point of worm), intermediate steering arm (when used) should be on center line of car, wheels should point straight ahead, and steering wheel position should be correct as noted below. Check steering wheel position as follows:

Chrysler, DeSoto, Dodge, Plymouth: Steering wheel hub, gear arm, tube, and gear roller shaft are machined with master serrations to place wheels straight-ahead when steering wheel is in its center position. No attempt should be made to change relative position of these parts by altering master serrations. Improper positioning of steering wheel should be corrected only by adjusting tie rods.

Ford Pass. Cars: When steering wheel is on the high point, the front wheels should be in a straight ahead position, spokes of steering wheel horizontal and steering gear arm pointing directly forward. Check steering wheel spoke position while driving car straight ahead. If spokes not in horizontal position, adjust as follows: Set steering wheel spoke in horizontal position. Scratch a mark on each steering arm connecting rod sleeve and the spindle connecting rod tube, then loosen sleeve clamp bolts. If left-hand steering wheel spoke was below horizontal when checked, turn both connecting rod sleeves downward the same amount. One complete turn of sleeve equals approximately one inch of steering wheel rim travel. Turn connecting rod sleeves upward if left-hand wheel spoke was above horizontal. Tighten sleeve clamp bolts to 12-15 ft. lbs. torque.

Ford Trucks: Place front wheels in straight-ahead position, place steering wheel on steering shaft with single spoke facing straight down. Using a wood block, tap steering wheel in center of hub until firmly seated on steering shaft.

Frazer, Henry J. Kaiser: Column shaft and steering wheel serrations have "flats" which must be matched when wheel installed. If wheel spokes not horizontal with front wheels straight ahead, adjust as follows: Disconnect drag link, locate steering wheel in center position (turn wheel back ½ full travel from either end position) with steering gear roller on "high" mid-point of worm and wheel spokes horizontal, set front wheels in straight ahead position. Adjust both tie rods for correct toe-in and with idler lever in centered position. Then adjust drag link until it can be re-connected without disturbing position of steering wheel or front wheels.

Lincoln & Mercury: To align steering wheel disconnect connecting link at steering gear arm, locate steering wheel in center position (turn wheel back ½ full travel from either end position) with steering gear roller on "high" mid-point of worm and wheel spokes horizontal, set front wheel in straight-ahead position. Adjust both tie rods equally until connecting link can be reconnected to steering gear arm without disturbing position of steering wheel and front wheels.

▷*CAUTION*: Both tie rods must be adjusted equally (turn both adjusters equally in opposite direction) to avoid disturbing original toe-in setting. Recheck toe-in after adjustments have been made.

Hudson 6 & 8 (1946-54): Notch in end of shaft should point straight down (visible with horn button and contact plate removed) and steering wheel spokes should be horizontal with roller on "high" mid-point of worm. If wheel position not correct, adjust by shifting shims from one ball seat to the other in the steering arm end of drag link.

Hudson (1955), Nash, Rambler: Steering wheel marked on underside of hub. Install steering wheel with this mark straight down and in line with wide serration on upper end of steering gear tube. In this position, steering gear roller should be on "high" mid-point of worm and front wheels should point straight ahead.

Packard: Place steering wheel in straight-ahead position and center steering gear on high spot. Adjust steering cross tube sleeves until wheels are in the straight-ahead position.

Willys, Pass. Cars: With steering gear in mid-position and wheels in straight-ahead position (lever arm installed on lever shaft), install steering wheel with spokes of wheel positioned parallel with vehicle floor.

STEERING WHEEL & HORN RING OR BUTTON REMOVAL

▷*INSTALLATION NOTE—Where installation instructions are omitted (below); reverse removal procedure. Special instructions are not required.*

Chrysler, 1946-51 All Models Except Hydraguide:

Horn Ring Removal—Disconnect horn wire at bottom of steering gear. Remove screws from underside of horn ring and remove cover, horn ring and ring retainer. Remove screws attaching contact ring and spring retainer to wheel hub and remove these parts. Pull horn wire out of steering tube.

Steering Wheel Removal—Remove steering wheel nut and install steering wheel puller Tool C-612 and pull wheel from shaft.

Chrysler, 1952-55 All Models Except Hydraguide:

Horn Ring Removal—Disconnect battery and center steering wheel in straight ahead position. Press down on horn ring ornament and turn counterclockwise. Lift out ornament retaining spring and pad. Disconnect horn wire from terminal on travel plate and insulator assembly. Remove bushing, travel plate, horn blowing contact ring spring and triangular ground plate. Curl and push wire into steering tube to make room for steering wheel puller pilot.

Steering Wheel Removal—Remove steering wheel nut and install steering wheel puller Tool C-612 (1952-54), Tool C-3428 (1955) and pull wheel from shaft.

CONTINUED ON NEXT PAGE

GEMMER WORM & ROLLER
(Con.inued)

DeSoto, 1946-55 All Models Except Hydraguide: Same as Chrysler instructions

Dodge, 1946-48 All Models:

Horn Ring Removal—Disconnect wire at connector below gear, then remove screws from underside of wheel hub and lift off horn ring and cover Remove screws attaching top plate to hub (if any) and remove plate Pull wire from steering tube

Dodge, 1949-50 All Models

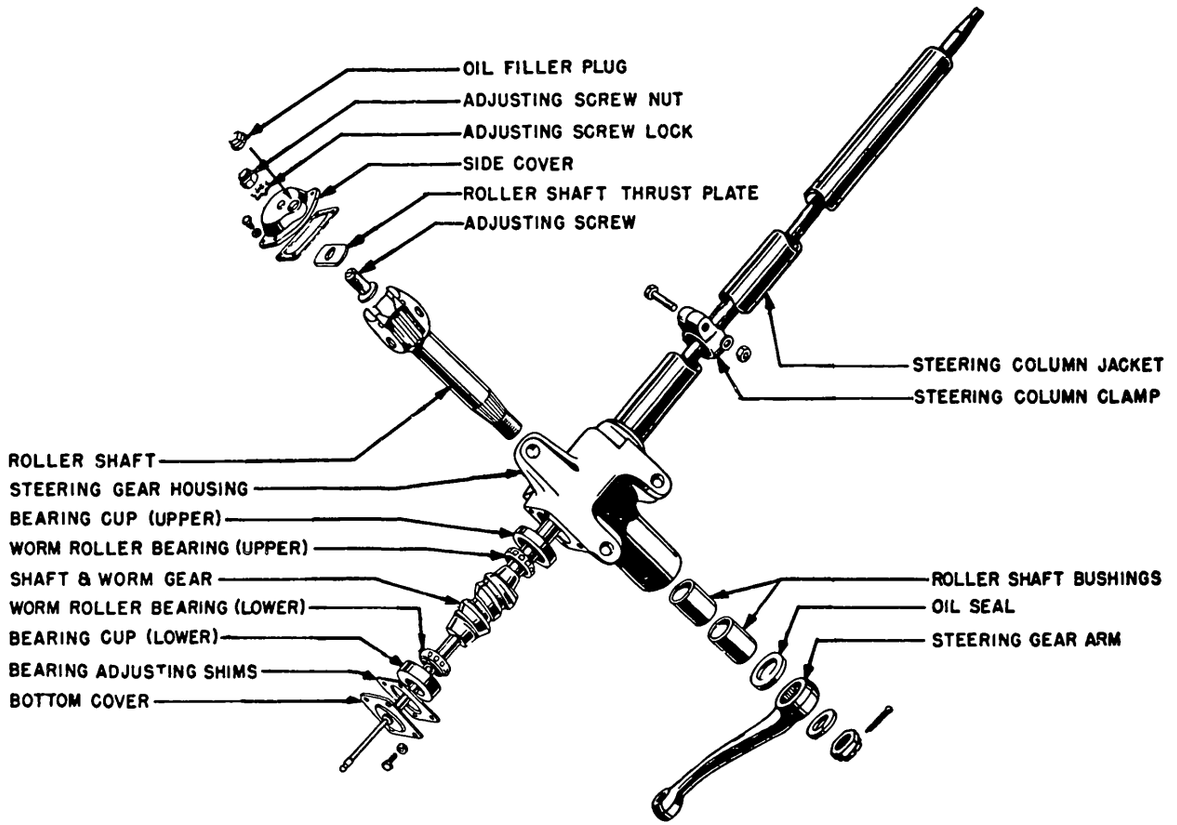
Horn Button Removal—Disconnect wire below steering gear, on some models, or at horn relay On 1949 models remove the screws from underside of wheel hub and remove medallion and horn ring On 1950 models, pry up the medallion and bezel and remove screws holding horn blowing ring Remove screws holding contact plate and wire to hub Lift off plate and wire, then remove spring.

Dodge, 1951-54 Except Some 6 Cyl. Models: See below

Horn Ring Removal—Disconnect horn wire at connector near bottom of steering column, push down on horn blowing ring medallion, turn clockwise and remove medallion, retainer spring and cushion Loosen and remove the three horn ring retainer screws and spacer bushings, then lift out horn ring, travel plate and insulator assembly, wire, contact spring plate and ground plate

Horn Button Removal (Some 6 Cyl. Models)—Disconnect horn wire at connector near bottom of steering column, turn horn button medallion retainer ⅛ turn counter-clockwise, lift off horn button, horn button retainer, contact spring and plate Pull out horn wire and spacer bushing from center of steering tube After removing steering wheel nut, lift out horn button contact cup, remove screw holding horn button retainer fastening plate and base to steering wheel

Installation—Be sure contact spring plate, on models with horn blowing ring, is installed with colored dot appearing on top side On all models, align master serration on steering tube with serration on steering wheel hub before installing



Dodge, 1955 All Models.

Horn Ring Removal—Disconnect battery and center wheel in straight-ahead position Remove two screws from underside of the medallion and remove medallion Disconnect horn wire from terminal on travel plate and insulator and remove horn ring, travel plate, and insulator assembly, contact spring and ground plate Push horn wire down into steering tube

Steering Wheel Removal (All Dodge Models)—Remove wheel nut and washer Attach wheel puller Tool C-612 by means of the threaded holes in steering wheel hub and remove wheel *NOTE*—When installing steering wheel, be sure that master serrations are in line and the direction signal cancelling cam on bottom of wheel is inserted between switch levers

Ford, 1946-48 Passenger Car Models:

Horn Ring & Horn Button Removal—Disconnect wire below steering gear Press down on button or ring and turn counter-clockwise and remove Take out spring

GEMMER MODEL 305 & 335 STEERING GEAR

Steering Wheel Removal—Remove steering wheel nut, install steering wheel puller Tool 3600-N and remove wheel from shaft.

Ford, 1952-55 Passenger Car Models:

Horn Ring or Button Removal—Disconnect horn wire from connector at bottom of steering gear housing Remove horn button or ring by pressing down and turning counter-clockwise Lift spring from steering wheel hub Pull horn wire and contact assembly out of steering shaft

Steering Wheel Removal—Remove steering wheel nut and remove wheel with Puller 3590-N

Installation—Align master splines, tighten nut to 50-60 ft lbs

Ford Trucks, 1946-55. See Passenger Car instructions and note the following

Steering Wheel Installation (Trucks)—Place front wheels in straight-ahead position, place steering wheel on shaft with single spoke facing down Using wood block, tap steering wheel in center of hub until firmly seated Stake end of shaft to nut at one point

Frazer, 1947-50 Except Manhattan

Horn Button Removal—See Kaiser 1947-48 (below)
Steering Wheel Removal—Remove nut and install steering wheel puller (1947-48) C-232; (1949-50) KF-26, and remove wheel.

Frazer, Manhattan 1947-50 & All Models 1951

Horn Ring Removal—See Kaiser Deluxe 1949-50 (below).

Steering Wheel Removal—Remove steering wheel nut and install steering wheel puller KF-26 and remove wheel.

Henry J, 1951-54:

Horn Button & Horn Ring Removal—Carefully pry medallion out of horn ring or horn bezel Turn contact plate one-third of a turn and lift it out of spacer Disconnect horn cable assembly from inside engine compartment and pull it out through top end of steering column tube Remove steering wheel nut and remove ground cup Lift horn bezel or horn ring from steering wheel and remove rubber cushion ring

Steering Wheel Removal—Pull steering wheel off with Puller C-232

Hudson, 1946-47 All Models:

Horn Button Removal—Push down and rotate horn button to release it from retainer. Disconnect horn wire at lower end of column and pull wire up slightly, then push wire sleeve up into large opening of

CONTINUED ON NEXT PAGE

GEMMER WORM & ROLLER (Continued)

contact cap. Remove contact cup from retainer. Remove steering wheel nut to remove retainer.

Horn Ring Removal—Remove two screws from underside of wheel and one sheet metal screw from bezel. Remove bezel and take out wheel to horn wire strip. Remove horn ring spring retainer screw, lockwasher and silencer rubber. Remove ring ornament spring nuts, contact clip, contact strip and bakelite spacer. Remove ring spacer upper spacer screw. Remove ring spring retainer and lift out spring. Remove horn wire, upper terminal, insulator, rubber sleeve and lower terminal. Lower spring retainer is held by wheel nut.

Steering Wheel Removal—Remove wheel nut and install steering wheel puller Tool J-739 and adapter J-739-7, and remove wheel.

Steering Gear Installation—Spokes of wheel should be horizontal with front wheel pointing straight ahead. Notch in steering shaft will be pointing down.

Hudson, 1948-54 Except Jet Models:

Horn Button Removal—Push down on button and rotate to release from retainer. Pull wire up slightly and push wire sleeve into large opening of contactor. Lift out contact cup and remove horn wire.

Horn Ring Removal—Disconnect horn wire at horn relay. Pry ornament and ring assembly out of steering wheel spoke cover. Remove three screws attaching horn ring insulator to horn ring. Remove insulator ring, contact cup and wire.

Steering Wheel Removal—Place adapter Tool J-739-10 around jacket tube with small diameter of adapter under steering wheel hub. Position foot of puller J-739-B around outside diameter of adapter. With steering wheel nut partially threaded on the column tube, run puller screw down tight against the wheel nut to release steering wheel.

Steering Wheel Installation—Install wheel on shaft with two spokes horizontal and notch in steering shaft pointing straight down. On wheels with three spokes, third spoke should point down. Torque nut to 20-30 ft. lbs.

Hudson Jet, 1953-54:

Horn Button Removal—Disconnect horn wire at horn relay and push down on horn button, rotate to release and remove button. Remove horn wire assembly.

Steering Wheel Removal—Remove steering wheel nut and pull steering wheel, using Puller J-3044.

Steering Wheel Installation—Same as other Hudson models. See above.

Hudson, 1955 All Models: See Nash & Rambler, 1949-55.

Kaiser, 1947-48 All Models & 1949-50 Kaiser Special

Horn Ring Removal—Insert a screw driver between medallion and wheel hub and gradually work the medallion out. Disconnect horn wire at lower end of steering gear. Remove two screws attaching contact plate in steering wheel to horn ring. Remove horn ring by pulling it away from underside of wheel. Remove the three screws attaching contact plate to wheel and take out insulators and washers. Pull horn wire through steering column and remove rubber pad.

Steering Wheel Removal—Remove nut and install steering wheel puller (1947-48) C-232; (1949-50) KF-26, and remove wheel.

Steering Wheel Installation—Install wheel with wide flutes or flat spots in hub or shaft serrations matching. Push wheel down and install nut. Tighten to 10-15 ft. lbs.

Kaiser Deluxe 1949-50

Horn Ring Removal—Disconnect horn wire below steering gear. Remove screws from underside of spokes and lift off medallion and retainer. Remove steering wheel (see below) and disassemble horn from wheel by removing necessary screws.

Steering Wheel Removal—Remove steering wheel nut and install puller Tool KF-26, remove wheel.

Steering Wheel Installation—Install wheel with the wide flutes or flat spots in the serrations in wheel hub and steering shaft matching. Push wheel down and install nut. Tighten to 10-15 ft. lbs.

Kaiser, 1951-55 All Models:

Horn Ring Removal—Press down on medallion and turn counter-clockwise to loosen. Remove medallion and rubber pad from wheel. Disconnect horn button at bottom end of steering gear, then remove insulator sleeve fitted into top end of steering column. Remove steering wheel to shaft nut and take off the horn bezel, or horn ring. Remove rubber contact pad (and ground spring and plate on some cars). Remove screws from contact plate and separate parts from bezel or horn ring.

Steering Wheel Removal—Install steering gear puller KF-26 and remove wheel.

Steering Wheel Installation—Install wheel with flat spots in hub serrations matching with flat spot in shaft serrations. Push wheel down as far as it will go and install horn parts and shaft nut. Tighten nut to 10-15 ft. lbs.

Lincoln & Mercury, 1946-48 All Models: See 1946-48 Ford Passenger Car instructions.

Lincoln & Mercury, 1949-51 All Models

Horn Ring Removal—Remove cap and emblem assembly from retaining clips in steering wheel (Lincoln); remove two screws from underside of steering wheel (Mercury). Remove horn ring spring and take out contact plate and horn contact parts.

Steering Wheel Removal—Remove steering shaft nut and install Tool 3600-D. Remove wheel.

Lincoln, 1952-55:

Horn Ring Removal—Remove cap and emblem assembly by grasping with the hand and pulling outward from steering wheel hub. Remove three screws holding horn ring securing plate to steering wheel. Remove horn ring securing plate, gasket and spring.

Steering Wheel Removal—Remove steering shaft nut. Install Tool 3600-D and remove steering wheel.

Mercury, 1952-55:

Horn Ring Removal—Remove cap and emblem assembly from steering column head by rotating cap counterclockwise with palm of the hand. Remove three screws holding horn ring retainer plate to steering wheel. Remove horn ring, retaining plate and spring.

Installation Note—When installing horn ring spring, be sure that spring ends are properly seated in spring stops.

Steering Wheel Removal—See Lincoln, above.

Nash & Rambler, 1949-55 All Models:

Horn Ring Removal—Rotate steering wheel medallion counter-clockwise to remove. Remove horn contact plate and insulators. Remove wheel (see below). Remove horn ring after wheel removed.

Steering Wheel Removal—Remove steering wheel nut and install steering wheel puller Tool J-2982.

Packard, 1946-55 All Models:

Horn Ring Removal—Depress medallion slightly, rotate counter-clockwise until it pops up (do not pry up). Remove horn ring assembly and contact plates.

Steering Wheel Removal—Remove steering wheel nut and install steering wheel puller Tool J-2557 and remove wheel.

Plymouth, 1946-55:

Horn Button or Horn Ring Removal—On models with a horn button, remove screws from underside of wheel and remove horn button retainer. Lift out button, spring base assembly. Contact cup can be removed after steering wheel removed. On models with horn ring assembly, two types are used. With the "one-piece" type, depress the ornament carefully and rotate it counter-clockwise. Remove ornament, spring and rubber grommet. Remove the three retainer screws and lift off ring. With the "two-piece" type, the ornament is held with four clips in hub cover. Pry hub cover upwards and remove the three retainer screws. Remove horn ring retainer and horn ring.

Steering Wheel Removal—Remove nut and install puller C-612 and pull wheel from steering tube.

Willys, 1952-55 Passenger Cars:

Horn Ring Removal—Disconnect horn wire at connection just below steering gear housing. Remove steering wheel hub cover by turning counter-clockwise ⅛ turn and disengaging. Remove flat springs from slots in horn ring cup. Pull up horn wire sufficiently to remove contact button, sleeve, spring and cup.

STEERING GEAR REMOVAL & INSTALLATION

▷*INSTALLATION NOTE—Installation procedures are the reverse of those for removal.*

Chrysler & DeSoto, 1946-48: Removal—Remove steering wheel. Remove screws holding column to instrument panel and screws on steering column at gearshift bracket. Disconnect direction signal control wires at instrument panel (two of these wires pull out of connectors and third is unscrewed from flasher unit terminal). Remove cover plate from bottom of direction signal control housing. This allows control unit to be removed directly while pulling wires up through jacket tube. Remove screws from rubber draft pad. Remove nut from lower end of gearshift rod and pull out rod and shift lever. Remove brake cable clamp and selector lever from steering column. Disconnect steering pitman arm (Puller C-143). Remove cap bolts attaching steering gear housing to frame, and remove left engine splash pan. Steering gear assembly can then be removed by lowering housing out through opening between engine and frame.

Chrysler & DeSoto, 1949-50: Removal—See Removal for 1946-48 Models above and note the following: Remove steering gear away from starter to permit

CONTINUED ON NEXT PAGE

GEMMER WORM & ROLLER (Continued)

removal of pitman arm. Steering gear assembly is then removed from above through hole in toeboard.

Chrysler & DeSoto, 1951-54: Removal—Remove clutch, brake, and accelerator pads, then remove shroud from bottom of steering column jacket and hand brake. Fold carpet back out of way from pedals and steering column, remove steering column draft pads. Disconnect accelerator rod from bell crank just behind firewall in engine compartment. Remove screws from floor board, accelerator pedal and rod assembly. Remove hairpin clip, disengage rod from transmission cross-over lever, disconnect horn wire from its connector. Disconnect six turn signal wires by pulling three wires out of each connector plug. Disconnect transmission shaft rod from shaft lever control arm. Three bolts attach steering gear assembly to frame bracket. REMOVE ONLY TWO TOP BOLTS which can be reached from under hood. Remove drag link, starting motor, and steering arm (Tool C-143). Remove bolt that attaches master cylinder pushrod to brake pedal. Remove brake pedal bushing lock and slide pedal outward on shaft far enough to clear pedal return stop screw. Move pedal back toward rear of car, allowing sufficient clearance between clutch and brake pedal in order to install Steering Chuck Assembly. Reach through floor board opening (from front compartment), remove lower bolt that holds gear assembly to lower end of frame bracket. Remove steering column shroud to instrument panel screws, remove steering assembly.

Chrysler & DeSoto, 1955: Removal—*(NOTE*—It is not necessary to remove the complete steering column and mast assembly from the car for servicing gear chuck and worm shaft). Remove steering wheel (see above). Loosen jacket bracket bolts at instrument panel. Remove dust pad retaining screws. Raise front of car and remove steering gear (pitman) arm from gear shaft. Loosen jacket-to-gear chuck clamp bolt. Remove gear chuck-to-frame attaching bolts and work gear chuck and shaft assembly out of jacket. Remove assembly from lower side of car.

Dodge, 1946-54: Removal—Remove steering wheel, jack up front of car and remove left front wheel. Remove front seat cushions and floor mat after sliding draft pad up column, then remove floor pan pedal opening cover. Disconnect directional signal control wires (if so equipped) at connections under instrument panel. Remove transmission shifting mechanism at steering column, remove bolts holding steering gear to frame. Remove pitman arm with Tool C-143. Remove steering gear post bracket cap at instrument panel. Remove steering gear assembly from top side of car by lifting up as far as possible then withdrawing from right side of car. **Removal Note**—If car is equipped with direction signals, time will be saved if length of wire is attached to loose end of control wires before withdrawing through jacket tube. This will enable all wires to be drawn back through tube at reassembly.

Dodge, 1955: Removal—Proceed as for 1946-54 Models but remove steering gear assembly by withdrawing it from underside of car. *(NOTE*—If steering column is to be removed, it must be removed from top side of car).

Ford Passenger Cars, 1952-55 (Except Thunderbird): Removal—Remove steering wheel (see above), then disconnect the steering column from the instrument panel and gearshift lever from gearshift rods. Remove cap screw from bracket that secures gearshift tube to steering column tube, remove bracket. Remove gearshift tube pin and gearshift levers. Loosen steering column clamp, pull steering column tube assembly off shaft. Disconnect steering arm-to-idler arm rod. Remove steering arm, then three bolts that secure steering gear housing to frame side rail, remove steering gear. NOTE—It may be necessary to raise car to remove gear.

Ford Thunderbird (1955): Removal—Disconnect wires at bottom of steering gear housing. Loosen the lower steering column clamp and remove the two screws from upper steering column bracket. Remove horn ring from steering wheel, and remove upper steering column, upper steering shaft, and steering wheel as an assembly from the car. Raise front of car and remove steering sector shaft arm from sector shaft, then remove bolts holding steering gear housing on frame side member. Remove lower steering gear assembly from car.

Ford Trucks (1946-55): Removal—Remove steering wheel. Remove steering column and brake pedal plate, remove bolt that secures steering gear arm to steering gear sector shaft. Remove the three bolts that secure steering gear housing to frame. Remove the clamp holding steering gear column tube to instrument panel bracket. Remove steering gear from underneath truck. *NOTE*—On some models it may be necessary to raise front end of truck to remove steering gear, and it may also be necessary to remove oil filters or filter adapters.

Henry J, 1951-54: Removal—Disconnect shifting rods from lower shifting levers mounted on steering column jacket in engine compartment. Loosen clamp that holds gearshift lower lever housing and steering gear housing on steering gear housing. **Do not remove screws.** Remove steering wheel, pull back floor mat, remove floor plate and seals around foot pedals and steering column. Remove steering column support bracket clamp and attaching bolts at instrument panel, remove spring and bearing spacer from upper end of steering column jacket. Work lower end of steering column jacket loose from steering column by pulling upward, inside the body. Shift levers must be carefully worked through floor pan opening as jacket is pulled upward. Disconnect tie rod from pitman arm, remove pitman arm nut and lockwasher. With Puller KF-119 remove arm from shaft. Remove steering gear-to-frame mounting bolts and shims (if used). Remove filler plug, invert gear, allow lubricant to drain. Remove steering gear by moving it forward and upward to clear other units.

Hudson, 1946-47: Removal—Disconnect battery cable at negative battery post and remove cable clip bolt and nut on fender. Disconnect horn wire at lower end of steering column. Remove steering gear jacket tube, clamp bolt and nut. Disconnect handy shift control wire, control tube rod, and remove tube lower bracket clamp bolt. Disconnect drag link at pitman arm and remove pitman arm with Puller J-1374. Remove horn button and wire, and remove steering wheel. Remove jacket tube bracket cap and bolts. Remove shift control tube upper bracket clamp bolt and ring. Slide jacket tube off steering gear main column tube and out of jacket tube clamp and control tube lower bracket. Remove shift control tube by working the lower lever up through hole in toe board. Disconnect radiator sway rod at dash and push out of way. Disconnect hood hinge at hood on right side. Remove steering gear housing mounting studs and remove steering gear by raising lower end up over engine and out of right hand side. This can be done by turning lower end frequently to obtain clearance.

Hudson, 1948-54: Removal—Remove left front wheel and fender side dust shield, remove left frame-to-cowl brace, then remove steering wheel and horn wire. Next, remove steering gear jacket tube by removing bearing spring and spacer, remote control tube (upper), direction indicator switch assembly (if so equipped), steering column bracket cap at instrument panel, then loosening control tube bracket (lower) and jacket tube clamp at steering gear, remove jacket tube. Remove three bolts attaching steering gear to frame side rail, remove key and plug from drag link at pitman arm, disconnect drag link. Slide steering gear forward on frame and rotate to left until pitman arm is clear, remove steering gear through opening in left front fender.

Hudson Jet, 1953-54: Removal—Remove battery, steering wheel and horn wire. Remove steering gear jacket tube by removing bearing spring and spacer, directional indicator switch assembly, steering column bracket cap at instrument panel, then loosening remote control tube bracket (lower) and jacket tube clamp at steering gear, remove jacket tube. Remove three bolts attaching steering gear to frame and nut at rear end of drag link, press ball stud out of pitman arm, using Puller J-1374. Slide steering gear forward on frame, remove steering gear by pulling chuck upward through engine compartment.

Hudson (Wasp & Hornet), 1955—See Nash Ambassador & Statesman, 1955.

Kaiser, 1947-55; Frazer, 1947-51: Removal—Disconnect battery cables at battery, remove battery to provide clearance for steering gear removal. Disconnect two shifting rods at shifting levers mounted on steering column jacket in engine compartment. On Frazer, loosen the clamp which clamps split lower end of steering column jacket onto steering gear housing. Remove steering wheel, then column jacket cover on those vehicles in which cover removal is necessary for access to column support at instrument panel. Disconnect horn wire at connector, and directional signal switch wiring at instrument panel junction block. Remove front floor mat and floor plate and gasket around pedals and steering column at toeboard. Remove steering column support bracket, clamp and attaching bolts at instrument panel, then spring and bearing spacer from around steering column in upper end of jacket. Leave bearing in jacket. On Frazer, work lower end of steering column jacket loose from steering gear housing. Then pulling upward inside body, slip the jacket, with gear shifting mechanism still attached to it, from upper end of steering column. The shifting levers must be carefully manipulated through the opening in the toeboard as the jacket is pulled upward. Remove splash pan from be-

CONTINUED ON NEXT PAGE

GEMMER WORM & ROLLER (Continued)

neath pitman arm. On Kaiser, detach shift mechanism from jacket. Remove arm nut and lockwasher. Using puller KF-2 remove lever arm from steering gear shaft. Remove steering gear to frame attaching bolts and shims (if used). Remove filler plug, invert steering gear, drain lubricant. Then, while supporting steering gear assembly, move it forward in engine compartment, raising housing end to clear adjacent units and radiator shroud, and at same time pulling steering column out through opening in toe board. When worked clear lift steering gear out of engine compartment.

Lincoln & Mercury, 1949-53: Removal—Remove pitman arm using Tool 3590. Remove steering wheel, then necessary floor covering and steering column-to- dash cover plate. Disconnect steering column electrical connections at junction points. Remove cotter pins, release shift rod from steering column shift arm. Remove two bolts on clamp that secure steering column housing assembly to steering column bracket assembly (secured to brake pedal support bracket). Loosen clamp on lower steering column at steering gear housing, remove steering shaft nut, spring, and sleeve from upper steering column. Remove steering column tube from steering shaft. On Lincoln, raise car, remove oil filter assembly, screw that secures clips holding heater tube, spark plug cables, and oil sending wire to engine block. Remove steering gear housing-to-frame bolts, then assembly through engine compartment from under car.

Lincoln & Mercury (1954-55): Removal—On models with Power Brakes, remove clamps that secure reservoir hose to fitting on brake booster cylinder and to the dash panel. Move the hose away from the steering column opening in the dash panel. On Lincoln, remove front seat cushion from vehicle and cover seat back to protect upholstery. On Mercury, move front seat to extreme rear position and cover seat and seat back to protect upholstery. On all cars, remove steering wheel with Tool 3600-D. Disconnect steering column electrical connections. Remove accelerator pedal from accelerator push rod. Remove brake and clutch pedals. Pull floor covering away from dash panel opening. On Lincoln, disconnect speedometer drive cable from instrument panel and pull through lower floor pan opening cover. On all cars, remove insulator and floor pan opening cover plates. Remove two capscrews that secure steering column bracket to instrument panel and pedal support bracket. Remove cotter pin(s) and release shift rod(s) from steering column shift arm(s). Loosen clamp on lower steering column at steering gear housing. Raise column sufficiently to disconnect wires at neutral switch on Automatic Transmission equipped models only. Remove steering column tube from steering shaft through inside of vehicle. Raise front of car and remove nut securing pitman arm to steering sector shaft. Remove steering gear arm (pitman) from sector shaft, using Tool 3590. Loosen three bolts that secure steering gear assembly to frame side rail. *(CAUTION—Remove shims, if any, located between mounting bolts and frame side rail. Mark bolt holes and number of shims required, to facilitate assembly. Mark shims for identification with bolt holes).* With helper in passenger compartment and another under vehicle, remove the three bolts that secure steering gear assembly to frame side rail, and remove unit through passenger compartment. CAUTION—Mask lower portion of instrument panel for protective purposes when removing unit.

Nash (Ambassador & Statesman) 1949-51: Removal—Remove steering wheel using puller J-2982. Remove shift rods from shift levers, and remove left heat deflector and control knob bracket. Disconnect steering jacket tube bracket at instrument panel, and loosen clamp bolt at lower end of jacket tube. With jacket tube loosened, turn it approximately 90° to the right to prevent contact with instrument panel while withdrawing the gear. Disconnect pitman arm from steering gear cross shaft, and tie rod on left side. With front of car in raised position, disconnect steering gear housing from body side sill and remove steering gear assembly from below.

Nash (Ambassador & Statesman) 1952-54: Removal—With standard gear puller, remove pitman arm from cross shaft. Disconnect gear shift rods from operating levers and steering gear housing from body side sill. Remove horn ring and horn blowing parts as an assembly, pull steering wheel. Disconnect all wires under dash attached to jacket tube (tag wires for reassembly). Slide rubber grommet up on jacket tube, fold floor mat toward center of floor, slide rubber insulator up to rubber grommet. Remove screws from clutch and brake pedal opening cover, slide cover up on pedal shafts. Loosen cap screws attaching pedal shafts to levers, remove pedal shafts and opening cover. Disconnect jacket tube from instrument panel. Loosen clamp bolt at end of jacket tube, slide steering gear from jacket tube.

Nash (Rambler) 1950-54: Removal—Remove horn ring and horn blowing parts as an assembly, pull steering wheel. Disconnect pitman arm from cross shaft and tie rod from left steering arm. Drain cooling system, remove radiator to water pump tube. Loosen clamp on lower end of steering jacket tube, remove steering gear mounting bolts from body side sill. Remove gear from under car over lower control arm.

Nash (Ambassador & Statesman) 1955: Removal—Disconnect shift rods at shift levers and pitman arm from shaft. Remove mounting bolts at steering gear housing and disconnect at the instrument panel bracket. Remove steering wheel. Disconnect all wires under dash that are connected to jacket tube. Remove complete assembly through access opening in toeboard.

Rambler (1955): Steering gear is removed from bottom of car without removing jacket tube. Remove steering wheel and drain cooling system. Remove radiator to water pump coolant line.

Packard, 1948-55: Removal—Disconnect horn button cable at bottom of steering gear case. Remove horn button and horn blowing ring. Disconnect directional switch cable connector and windshield wiper cable control at wiper motor. Remove steering wheel. Remove gear shift lever by disconnecting at its pivot pin. Remove clutch and brake pedal pads. Raise steering column grommets and left front corner of floor mat. Remove clutch and brake pedal cover plate. Disconnect low and reverse, second and direct shifting rods from levers at lower end of gear shaft. Remove gearshift to frame attaching bolts, then remove steering column-to-instrument panel bracket cap. Lift steering column and shroud assembly up through opening in floor board. Remove steering gear-to-frame attaching screws, remove steering gear from under bonnet.

Plymouth 1946-55: Removal—Remove steering wheel. Loosen toe board assembly, then remove lower half of instrument panel bracket, loosen steering column jacket clamp. Disconnect pitman arm, remove housing bolts at frame. Hold steering column jacket, slide gear assembly out from below, leaving jacket and gear shift controls inside car.

Willys (Pass. Cars) 1952-55 : Removal—Remove steering wheel lower housing, remote control shift lever and steering column trim cover. If equipped with directional signals, unscrew signal lever from switch, remove two switch mounting screws, disconnect wires and remove switch. Remove instrument panel to steering column bracket. Pull floor mat forward, remove toe board cover plate and heater grille and heater (if so equipped). Raise front end of vehicle 18", detach two remote control rods from clutch levers by removing cotter pins and washers from control rod trunnions. Remove nut from pitman arm, remove arm from shaft. Remove three mounting bolts from steering gear housing, remove steering gear and column from beneath car.

STEERING GEAR OVERHAUL

OVERHAUL (STEERING GEAR ASSEMBLY): Clean the outside surfaces of steering gear assembly thoroughly. Then mount assembly in vise, clamping the housing so both shaft and roller cover and the housing end cover are accessible.

Disassembly (Shaft and Roller Assembly): Remove shaft and roller adjusting screw, locknut and lockplate, then remove bolts attaching shaft and roller cover plate to housing. Turn adjusting screw clockwise to raise cover away from housing to allow adjusting screw to slide out of slotted end of shaft and roller assembly. Remove cover screw and gasket and disassemble adjusting screw and thrust washer from cover. Push upward on lower end of roller shaft and lift shaft and roller assembly from housing. *CAUTION—Do not try to disassemble roller from shaft as these parts are replaceable only as an assembly.*

Housing Cover Plate and Shims—Remove housing cover attaching bolts and take off cover, and shims used to adjust worm bearing *(Check total thickness of shims with a micrometer so it will be possible to use same thickness when assembling steering gear).*

Worm and Bearings—Remove lower worm bearing cup, lower bearing, and the worm and steering column assembly, and upper bearing. (The lower bearing cup can be loosened by tapping lightly on end of steering shaft with hammer). Remove upper bearing cup from housing by carefully driving it out with a brass drift. Remove roller shaft oil seal only if it needs replacement or if the roller shaft bushings are to be replaced.

Cleaning and Inspection—Clean all lubricant from parts and housing, using a stiff brush to clean bearings and worm and roller teeth. Check all parts for wear, pitting, chipping or scoring. Replace parts as necessary. Check fit of roller shaft in housing bushings. The shaft must not be loose, but it must not bind in bushings. Check shaft for roughness or wear. (See Bushing replacement below). Check con-

CONTINUED ON NEXT PAGE

GEMMER WORM & ROLLER (Continued)

dition of shaft and roller adjusting screw thread With the adjusting screw and thrust washer inserted in slotted end of roller shaft, clearance between head of screw and bottom of slot should not exceed 002" Replace adjusting screw and or thrust washer to obtain right clearance Roller on shaft must rotate freely If rotation is rough, if roller is loose or if there is endplay, shaft and roller assembly must be replaced Be sure there is no indication of twisting or distortion of roller shaft Steering column (shaft) run-out at upper end should not be greater than 250"

Bushing Removal and Replacement—Press old bushings from housing and install new bushings, pressing them into the same position as old bushings Line ream bushings after installation to 1 125-1 1255" Check roller shaft in bushings to make sure it is free Install a new roller shaft oil seal with correct side toward outside of housing

Reassembly (Worm and Bearings): Install upper worm bearing cup, driving it carefully into counterbore in housing, wide face of cup toward bottom of counterbore Do not cock in counterbore and make sure it is seated fully Apply steering gear lubricant to worm bearings, bearing cups and on the worm threads before installing in housing Fit upper worm bearing into place over end of steering column shaft and onto bearing surface at end of worm Install worm and shaft into housing so that bearing fits into bearing cup Fit lower bearing onto bearing surface on ower end of worm and install the lower bearing cup in housing, with tapered part of cup toward worm bearing

Housing Cover Plate and Shims—Select shims totalling same thickness as previously used, or use old shims if in good condition (Shims 002" 005" 010" are available as service parts) Install shims and cover on housing and tighten bolts to 10-15 ft lbs torque Steering column shaft should rotate freely and smoothly without binding and without endplay (See Adjustment below)

Shaft and Roller Assembly—Lubricate roller, roller shaft, and bushings with steering gear lubricant Then install assembly in steering gear housing being careful not to damage oil seal when passing shaft through seal Turn steering column shaft to mesh teeth of roller at center of worm Assemble thrust washer on roller shaft adjusting screw and turn screw into roller shaft cover Install this assembly and cover gasket on steering gear housing, fit head of adjusting screw and thrust washer into slot in roller shaft Turn screw counter-clockwise to seat cover against housing Install cover bolts and tighten securely

STEERING LINKAGE · *See "Steering Linkage."*

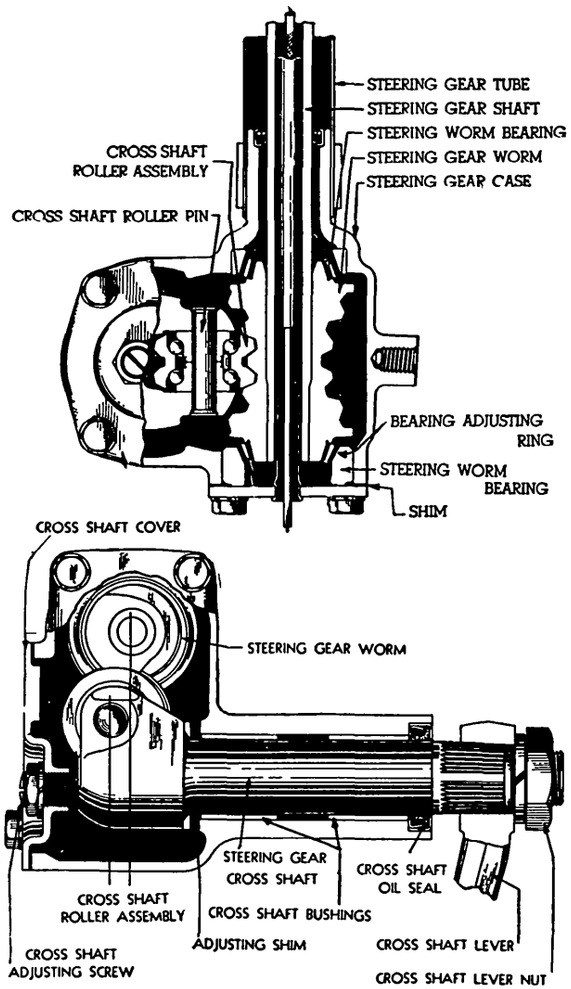
GEMMER WORM & ROLLER TYPES 330, 370

Car Model	Gemmer Model
Ford, All Bus Models (1941-48)	370
Lincoln, All Models (1941-48)	330

DESCRIPTION:—Consists of 'hour glass' type worm mounted on steering shaft and carried on roller bearings at top and bottom.

Model 370—Roller cross-shaft on this model is straddle mounted with additional bearing in side cover. Serviced in same manner as other types.

Lincoln Model 330—Steering gear has a straddle mounted roller shaft with additional shaft bushing mounted in side cover on housing. Adjusted in same manner as other models.



ADJUSTMENT:—Before making adjustments jack up front wheels and disconnect drag link to free steering gear (front wheels should turn freely with not more than 10 lbs. pull on drag link in either direction).

Worm Bearing Endplay:—Evidenced as up-and-down play of steering wheel. Check by turning wheel one turn to right from center 'straight ahead position', secure wheel, shake front wheels, note endplay. To adjust all models with shims under lower cover (see Note below for spring-loaded type), loosen four screws on lower cover, separate top shim, clip shim and remove using care not to damage other shims. Tighten cover screws and check adjustment. Wheel should turn freely without any stiffness or appreciable endplay

Spring Loaded Type—On this type gear, a spring washer is located under the lower worm bearing cup so as to control worm shaft endplay. Requires no adjustment. If this type gear develops endplay, remove lower cover and examine spring washer, replace if broken.

Roller Shaft (Cross-Shaft) Endplay:—Turn steering wheel to extreme end position and then back ⅛ turn. Check cross-shaft endplay at steering arm hub. To adjust, loosen locknut, turn up adjusting screw in inner cover until shaft turns freely with no endplay, tighten locknut.

Roller Mesh in Worm:—Turn steering wheel to center 'straight ahead position,' shake steering arm to determine play or backlash. If this exceeds 1/32", steering gear must be removed from car and roller shaft position adjusted. With gear out of car and held in vise, take off steering arm nut, remove steering arm, take off side cover, remove roller and cross-shaft. See that all shims on shaft behind roller are removed from housing. Remove steering jacket, replace wheel on steering shaft, check worm shaft bearing adjustment. Remove one shim, reinstall roller shaft, assembling roller shaft thrust washer with chamfered side next to roller shaft

thrust face. Check by turning steering wheel nearly to extreme left position, hold roller shaft in against worm, turn wheel to center position, check play at splined end of roller shaft. If play apparent, remove additional shim and repeat test. Replace housing cover, reassemble steering arm (drive arm in roller shaft), adjust roller shaft endplay (see above). If adjustments have been made correctly, play at ball end of steering arm should be .006" and wheel should turn throughout range without heavy drag.

CAUTION—Make certain that thick thrust washer (between adjusting shims and shoulder on roller shaft) is installed with bevel face or chamfer toward roller (away from splined end of shaft).

1949-51 FORD PASS. CAR WORM & ROLLER

Ford 6 Cyl. & V8 Pass. Car Models (1949-51)

▷STEERING LINKAGE PRODUCTION CHANGE (New Idler Arm Bracket & Pitman Arm) On Cars *After March 1, 1949: See Ford Passenger Car Front Suspension data for identification of these parts and NEW Front Suspension Settings required when they are used.*

▷*CAUTION—These new parts must be used together.*

▷STEERING IDLER ARM LOOSENESS COMPLAINTS: May be caused by incorrect adjustment. *See Idler Arm Adjustment under Steering Linkage.*

DESCRIPTION: Worm-and-roller type with worm gear on steering column shaft meshing with double-tooth roller on cross-shaft (sector shaft) on which the pitman arm is mounted.

ADJUSTMENT: Adjust exactly as follows:

Worm Shaft Endplay (Bearing Pre-load): Before checking, disconnect steering linkage at pitman arm and back off cross-shaft (sector shaft) adjustment (see below) so that the true bearing pre-load can be measured. Attach spring scale to wheel spoke at steering wheel rim, check turning pull.

Bearing Pre-load—½-1¼ lbs. turning pull.

Adjustment—Loosen steering column jacket clamp at bottom of instrument panel. Remove capscrews in top cover on steering column housing. Work cap and column jacket upward sufficiently to provide access to adjusting shims located between cap and housing, carefully separate first shim from remainder of shim pack, clip and remove shim (see Shim Note below). Work cap down on housing, re-install capscrews, recheck bearing pre-load. Repeat adjustment until correct bearing pre-load secured.

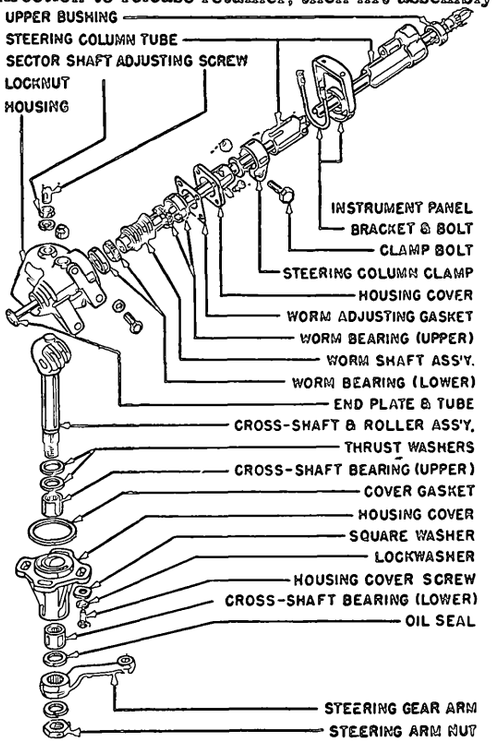
▷*CAUTION—Do not exceed bearing pre-load specifications and see that wheel turns freely throughout travel without binding or stiffness.*

▷Adjusting Shim Note—These shims furnished in four thicknesses as follows: Part B-3593A (.002"), B-3593B (.005"), B-3593C (.010"), B-3593D (.020").

Worm-and-Roller Mesh (Backlash): Check with steering wheel turned to center "straight-ahead" position (mid-point of travel at which backlash is at a minimum). Attach spring scale to wheel spoke at wheel rim, check pull required to turn wheel.

Backlash Setting—1¾-2 lbs. measured as above (this figure includes worm bearing pre-load of ½-1¼ lbs. adjusted previously).

Adjustment—Loosen sector shaft housing (bottom cover) capscrews (NOTE—not necessary to remove screws—screw holes slotted to permit this adjustment). Rotate housing in a clockwise or right hand direction until all backlash is just removed, tighten cover screws, recheck backlash setting (above). Repeat adjustment, as required, until correct backlash setting is secured. Make certain that square washer (adjusting slot cover plate) and lockwasher in place on cover screws and screws securely tightened.



▷*CAUTION—See that wheel turns freely through entire travel without binding or stiffness.*

Cross-shaft (Sector Shaft) Endplay: Loosen locknut on sector shaft adjusting screw (on top of housing), turn screw in (clockwise) until all endplay in shaft has been taken up without causing any binding as shaft is rotated, tighten locknut.

STEERING WHEEL REMOVAL: Remove horn button and ring assembly (see below), remove nut on steering column shaft, pull wheel.

Installation—Shaft and wheel hub have "master spline" so that wheel can only be installed in correct position. Pitman arm and steering gear cross-shaft have similar master spline to insure correct positioning of arm.

Horn Button & Ring Assembly Removal: Press down evenly on horn button and turn assembly in either direction to release retainer, then lift assembly out.

1949-51 FORD PASS. CAR STEERING GEARS

STEERING GEAR REMOVAL: Remove steering wheel and then remove steering column from instrument panel. Disconnect the lower gearshift levers from gearshift rod adjustment nuts. Remove cap screw from bracket that secures gearshift tube to steering column tube and remove bracket. Remove gearshift tube pin and gearshift levers. Loosen steering column clamp and pull steering column tube assembly off steering gear shaft. Remove steering gear pitman arm using Tool 3590-N. Remove three bolts securing steering gear housing to frame side rail. Remove steering gear from underside of car. *NOTE*—It may be necessary to raise car to remove gear.

STEERING GEAR OVERHAUL: Drain lubricant from housing and remove all dirt from outside of housing before starting disassembly.

Disassembly: Scribe an alignment mark on steering gear and sector housing to insure correct reassembly. Remove sector shaft housing screws, then remove sector shaft and housing. Remove two spacers from sector shaft and gasket from housing. Remove steering gear housing capscrews and slide cap off steering gear shaft. Pull steering gear shaft and gear assembly out of housing. Slide the steering gear upper cap gaskets (shim pack), bearing cup, and worm upper bearing off shaft. Tie gaskets together for use when assembling gear. Lift lower worm bearing and cup from housing. Press the sector shaft needle bearings, spacer and oil seal out.

Inspection: Clean all parts thoroughly, then inspect the worm and roller for scores, cracks, or for signs of chipping. Inspect steering shaft bearing cups and bearings for wear, cracks or damage.

Reassembly: Press bearings into sector shaft housing, one from each end, and install oil seal. Install the upper worm bearing, bearing cup and steering gear housing upper cap gaskets on worm and shaft assembly. Slide steering gear housing upper cap on steering shaft. Install lower worm bearing cup in steering gear housing, then position gear shaft and worm assembly in steering gear housing and install capscrews. Place the two thrust washers on sector shaft and worm assembly, then slide the shaft and worm assembly into steering sector shaft housing cover. Position steering sector shaft housing gasket on steering gear housing, then install the steering sector shaft housing cover on the steering gear housing with the marks in alignment.

STEERING GEAR INSTALLATION: From underneath car, position steering gear assembly on frame, and install but do not tighten mounting bolts and nuts. Install steering column tube assembly on steering shaft and secure steering column tube bracket to instrument panel. Tighten the steering column clamp, and then tighten the steering gear housing to frame bolts to 30-36 ft. lbs. torque. Install pin and lower gearshift levers. Place the gearshift tube bracket in position and secure tube in place with capscrew. Connect gear shift levers to the rod adjusting nut, install steering wheel. Position steering gear arm (pitman arm) on the sector shaft. (*CAUTION*—The arm should be installed pointing straight back when the wheel spokes are in a horizontal position and the worm is at mid point of travel). Install the lockwasher and nut, tighten to 110-130 ft. lbs. torque.

STEERING LINKAGE: Consists of an intermediate rod linked between the steering gear pitman arm and an idler arm pivoted on a bracket on the right side of the frame with individual tie rods.

After March 1, 1949: See Ford Passenger Car Front Suspension data for identification of these parts and NEW Front Suspension Settings required

Steering Linkage Adjustment: If linkage disconnected or out of adjustment, set linkage up as follows to insure correct steering wheel position: With linkage connected, and idler arm correctly adjusted (see below), turn steering wheel to center mid-point of travel (turn wheel from one end position to the other, counting the turns, then turn wheel back from end position one-half this number of turns) with spokes horizontal. Loosen clamp bolts on each tie rod and turn each tie rod adjuster, as necessary, so that both front wheels are in "straight-ahead" position. Then adjust toe-in or toe-out by turning each tie rod adjuster equally.

Steering Idler Arm Adjustment: Check idler arm for excessive looseness and adjust as follows: Remove bolts mounting idler arm bracket on frame. Tighten idler arm bushing in bracket to 85-100 ft. lbs. Turn idler arm bracket and bushing assembly down on arm until it is tight (this is left hand thread), then back arm and bushing off approximately 1 turn, re-install bracket mounting bolts.

ROSS CAM & TWIN LEVER

Studebaker, All Models (1946-55)①
Willys, Pass. Cars (1952-55)②
Willys, Utility (1946-55)

①—Saginaw Worm and Roller also used.
②—Gemmer Worm and Roller also used.

DESCRIPTION:—Consists of a worm-shaped cam mounted on the steering column shaft engaging two tapered studs mounted on the inner end of the cross-shaft lever. Cross-shaft is mounted on plain bushings and is adjustable for end-play. Cam is mounted on ball thrust bearings at upper and lower ends and bearing clearance or endplay is adjustable. Stud track in cam is grooved deeper at ends to provide minimum clearance at each stud in 'straight ahead' position. All adjustments must be made with wheel in straight ahead position.

ADJUSTMENT

ADJUSTMENT:—Before making adjustments, free steering gear from load by jacking up front wheels or disconnecting drag link. Check the gear alignment. If stiffness evident with instrument panel bracket clamp tight, align steering gear as follows: Loosen steering gear frame bracket bolts to allow gear to shift on frame, retighten frame bolts. Loosen instrument panel bracket bolts to allow bracket to shift into alignment with steering column, tighten bracket bolts (if bracket position not adjustable, shim or otherwise change bracket position so that column not sprung when bracket bolts tightened).

Cam Endplay Adjustment—Check up-and-down movement of steering wheel and shaft in steering column jacket. If adjustment required, first loosen locknut and back off adjusting screw on housing side cover to relieve bearings of side thrust. Then remove four retaining screws in top cover on upper end of steering gear housing, move cover up on column jacket as far as possible (about ¼"), clip and remove a thin shim in shim pack under cover (shims are installed between paper gaskets and are .003", .010", .030" or .002", .003", .010" thick), using extreme care not damage remaining shims and paper gaskets. Re-install cover, tighten cover screws, check adjustment. Wheel should turn with barely perceptible drag (4-7 ozs. pull on steering wheel rim) and should have no up-and-down movement. Then adjust Cam and Lever Backlash.

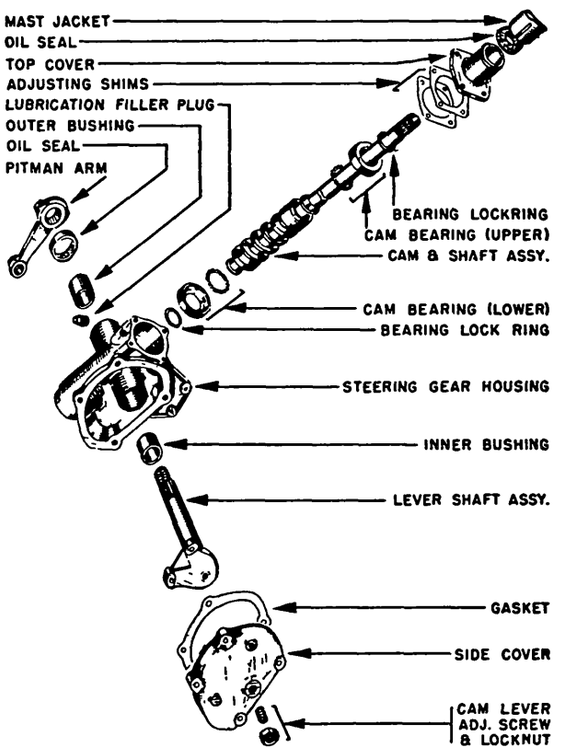
Cam and Lever Backlash—Check end-play or lost-motion of lever shaft at pitman arm with steering gear turned to center position with lever studs on high points of cam. If play evident, adjust by loosening locknut on steering gear housing side cover and turning adjusting screw in until play just taken up and steering wheel turns freely throughout entire range with drag at center high point 16-24 ozs. at steering wheel rim. Hold adjusting screw and tighten locknut.

►*CAUTION*—This adjustment must be made only with lever studs on high points of cam (straight ahead position). If adjusted in any other position, gear will bind at this center point.

STEERING WHEEL POSITION: Check steering wheel for correct installation as follows:

Studebaker Models—Steering wheel center spoke (3 spoke types) should point straight down, or spokes should be horizontal (2 spoke type) with steering gear in straight-ahead position and lever studs on high points of cam. To check, count number of turns of the wheel from one extreme end position to the other, then turn wheel back exactly one-half this number of turns. If steering wheel spoke position not correct, remove wheel and re-install on shaft in correct position. See Linkage data under "Steering Linkage."

Willys Models—With steering gear in mid-position and wheels in straight-ahead position (steering arm installed on lever shaft), install steering wheel with spokes positioned parallel with vehicle floor.



STEERING WHEEL & HORN RING OR BUTTON REMOVAL

Studebaker (All Models):

1946-49 All Models—(See Note Below for Deluxe Steering Wheel). Remove horn button or ring by holding steering wheel stationary and turning button or ring 1/3 of a turn. Remove wheel retaining nut and install steering wheel puller Tool J-1594, remove wheel.

Installation—Rotate steering shaft through the entire travel and count number of revolutions. Then rotate shaft in opposite direction 1/2 the total amount of travel. Replace steering wheel with two spokes horizontal and install wheel.

►**Deluxe Steering Wheel Note**—To remove horn ring, pry horn button out of wheel and remove the three screws in horn ring, remove ring, sponge rubber pad and three insulators. Install by reversing removal procedure.

ROSS CAM & TWIN LEVER STEERING EAR

1950-51 All Models—Remove horn button or horn ring (See instructions above, horn button removal is the same). Then proceed as follows:

1950-51 All Models (Except 1950 Champ. & 1951 Champ. Custom)—Remove horn ring or bar and the rubber shock pad. Remove steering wheel retaining nut. Install the two halves of adapter plate J-4146-9 at base of steering wheel. Place adapter in the end of steering shaft, being sure horn wire is in slot provided in adapter. Install puller cross-bar and screw and remove steering wheel.

1950 Champion & 1951 Champion Custom—Install steering wheel puller J-1594 below wheel hub. Remove steering wheel retaining nut and install puller HM-925 and remove wheel.

Installation 1950-51 All Models—Align mark on top of steering wheel hub and mark on end of steering shaft and install wheel. Install retaining nut and tighten to 23-27 ft. lbs.

1952-55 Champion (Custom & Deluxe): Removal Remove horn button or ring by holding steering wheel stationary and turning button or ring one-third turn. Remove steering wheel nut, install puller J-5473, remove steering wheel.

1953-55 Champion & Commander (Regal), All President Models: Removal—Pry horn button out of wheel, remove three screws in horn ring, remove ring and sponge rubber pad. Remove steering wheel nut and lock plate. Install adapter in end of steering post, install puller J-5473, remove steering wheel.

Installation (All 1953-55 Models)—Align marks on top of steering wheel hub and mark on end of steering shaft, install wheel. Tighten retaining nut to 23-27 ft. lbs. torque. To install horn ring or button, reverse removal procedure.

Willys (1947-55): Removal—Disconnect horn wire at slip connection just below steering gear housing. Remove steering wheel hub cover by turning counter-clockwise ⅛ turn and disengaging. Remove flat spring from slots in horn ring cup. Pull up horn wire sufficiently to remove contact button, sleeve, spring and cup. Remove steering wheel nut, install puller W-227, remove steering wheel.

STEERING GEAR REMOVAL & INSTALLATION

Studebaker (1950-54): 1. Remove the horn button and the steering wheel, remove front seat cushion. Disconnect and remove battery. If equipped with Automatic Drive, disconnect quadrant light and starter cut-out switch cable. Disconnect shift lever rod or rods, loosen jacket clamp bolt. Remove jacket bracket retaining bolts from instrument panel, loosen jacket bracket clamp screw, turn bracket to avoid hitting instrument panel when removing jacket. Slip jacket off steering post as an assembly into inside of car. Disconnect reach rod from pitman arm, remove steering gear housing-to-frame bolts. Tip upper end of steering post down, remove steering gear assembly from engine side of cowl. Wrap cloth around top of housing top cover to prevent spilling of lubricant, then lift housing end of assembly up and remove it from chassis.

2. Before installing the jacket and gearshift shaft assembly, install housing-to-frame bolts but do not tighten until jacket and jacket-to-instrument panel bracket bolts have been installed.

C NTINUED ON NEXT PA E

ROSS CAM & TWIN LEVER (Continued)

3. Position jacket and gear shift shaft assembly so shift rods are aligned with hole of shift lever. Install gear shift control box clamp and key on the Commander. On Champion tighten steering post jacket clamp. Remove aligning gauge and install plug in cover.
4. Check alignment of housing mounting face flange with frame side rail. Insert spacing washers as necessary to secure proper alignment.

Studebaker (1955): Disconnect battery and disconnect horn switch wire at connector. On Commander & President models, also disconnect battery cable at starter switch. On Commander and President Convertible (Hardtop) and Coupe models, remove battery and battery box. Remove steering wheel and steering post jacket assembly (*NOTE*—Steering gear housing, steering post jacket, and steering wheel can be removed as an assembly. However, on Commander & President Convertible (Hardtop) and Coupe models, it will be necessary to remove left front engine support cushion and raise left front corner of engine approximately 2"). Remove pitman arm using puller J-5664, then remove steering gear housing-to-frame bolts and remove steering gear through hole in dash and into car. Wrap a cloth around steering gear housing top cover to prevent spilling lubricant during removal. To install, reverse removal procedure. Before installing jacket and gearshift shaft assembly, install housing-to-frame bolts but do not tighten until jacket and jacket-to-instrument panel bracket bolts have been installed. Check alignment of housing mounting flange face with frame side rail, inserting washers as necessary to secure proper alignment and high spot adjustment.

Willys Utility Models (1946-55): It is necessary on these models to pass the steering gear down through floor pan (on all Jeeps, remove left front fender). Disconnect remote control rods from transmission control levers on models with remote control. Remove horn button and steering wheel and remove steering post bracket at instrument panel. Remove gear shift levers on cars with remote control. Remove exhaust pipe from manifold. Remove steering column cover plate on toe board, and take out the two screws attaching remote control housing to steering column. Remove horn wire contact brush CJ-2A Jeep) or disconnect horn wire. Remove the remote control assembly through floor pan (CJ-2A). Remove steering connecting rod from steering gear ball arm and take out steering gear housing-to-frame bolts. Remove steering gear assembly by bringing it down through floor pan and over the outside of the frame side rail.

Willys Pass. Cars (1952-55): Remove the steering wheel lower housing, remote control shift lever and steering column trim cover. If equipped with directional signals, unscrew signal lever from switch, remove two switch mounting screws, disconnect wires and remove switch. Remove instrument panel to steering column bracket. Pull floor mat forward, remove toe board cover plate and heater grille and heater (if so equipped). Raise front end of vehicle 18", detach two remote control rods from clutch levers by removing cotter pins and washers from control rod trunnions. Remove nut from pitman arm, remove arm from shaft. Remove three mounting bolts from steering gear housing, remove steering gear from beneath car.

OVERHAUL (STEERING GEAR ASSEMBLY): Disassembly—Loosen cam lever adjusting screw locknut, back off adjusting screw two turns. Remove side cover screws and washers, remove side cover, drain lubricant from housing. Remove pitman arm, then cam lever shaft from housing. Remove upper plate cover screws, then remove cover, lower oil seal, and adjusting shims. Withdraw post and cam assembly from housing. Remove ring from lower end of cam to permit removal of lower cup and ball bearings. Remove upper bearing cup ring, bearing cup, and ball bearings. Remove oil seal and gasket from cam lever shaft bore and, using a suitable arbor, press inner and outer bushings out.

Reassembly: With suitable arbor, press bushings into place in cam lever shaft bore of housing. Bushings should be line-reamed to fit cam lever shaft. Assemble cam bearings, cup, and rings on cam and post assembly, install assembly in housing. Assemble top cover and shims on housing, check bearing adjustment, remove or add shims as required. Install cam lever shaft, housing cover gasket, and cover, tighten cover screws securely. Install lever shaft gasket and oil seal, install pitman arm.

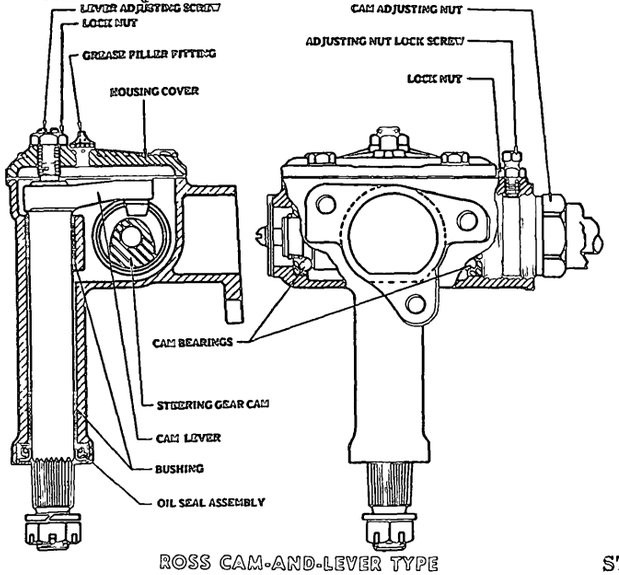
STEERING LINKAGE: *See "Steering Linkage."*

ROSS CAM-AND-LEVER

Crosley, All Models (1946-52).
Metropolitan, Hudson & Nash Models (1954-55).

DESCRIPTION: Consists of a worm-like cam mounted on steering wheel shaft engaging a tapered stud mounted on inner end of cross-shaft lever.

ADJUSTMENT: Free steering gear from load by disconnecting drag link or jacking up front end of car. Loosen instrument board bracket clamp, loosen jacket tube clamp screw (if no clamp screw used, jacket tube is press-fit in adjusting plug and will turn with plug). Make adjustments in order:



Cam Endplay (Shim Type):—Unscrew four clamp screws in upper cover, move cover up as far as possible (about ¼"). Separate top (.003") shim from remainder, clip and remove. Replace upper cover screws and tighten securely. Check adjustment. Wheel should turn freely (with light grip on rim) without any up-and-down movement with barely perceptible drag at mid-point.

Lever Shaft Endplay (Steering Wheel Backlash):—Turn wheel to straight ahead position so that stud at high point of cam. Never adjust with stud at other points. This will cause binding at center position. Loosen locknut on side cover adjusting screw (on inner cover plate), turn screw up until slight drag felt at center position when wheel turned from one extreme to other, tighten locknut. Drag must be slight and perceptible only in midposition.

STEERING WHEEL POSITION:

Metropolitan, Nash & Hudson Models—Steering wheel spokes should have equal angles to the horizontal with wheels in straight-ahead position and lever stud on high point of cam. If steering wheel not correct, remove and install without disturbing position of front wheels and lever stud.

STEERING WHEEL & HORN BUTTON REMOVAL: Metropolitan, Hudson & Nash Models: Loosen three set screws in the steering wheel hub and remove direction switch and horn button assembly from steering wheel. (NOTE—When removing steering wheel use puller J-1270-N.

ROSS CAM-AND-LEVER TYPE

STEERING GEAR REMOVAL & INSTALLATION: Metropolitan, Nash & Hudson Models: Remove radiator, air cleaner, intake manifold drain line, and top brace for carburetor air cleaner. Disconnect and mark direction signal switch and horn wires at plug-in type connectors in engine compartment. Disconnect shift rods from gear shift operating levers. Remove steering gear support bracket from inner wheelhouse panel, and from steering gear. Remove nut, ball, and gear shift knob from gear shift lever, then remove gear shift lever, shift shaft, operating levers and bracket as an assembly. Remove direction signal switch and horn button assembly and steering wheel (see above). Remove steering jacket tube upper support cushion and retainer attaching screws. Disconnect left hand instrument panel-to-dash brace at panel, and remove lower left instrument panel attaching screw. Remove pitman arm nut with remover J-5566. (*NOTE*—It is not necessary to remove steering linkage from arm.) Remove steering gear attaching bolts. Move steering gear housing toward center of car and pull it as far forward as possible. Pull instrument panel away from dash until upper end of steering worm tube and jacket tube clear hole in panel. Remove gear shift lever mounting bracket, rubber cushion, cushion retainer, and jacket tube rubber grommet from steering jacket tube. Move steering gear forward, guiding it around engine manifolds and fuel pump, until gear housing contacts grille. Lower upper end of jacket tube and slip it under steering linkage across tube and floor panel. Move steering gear out to rear

STEERING LINKAGE: *See "Steering Linkage."*

SAGINAW WORM & ROLLER

Oldsmobile 6 & 8, All Models (1946-49)
Oldsmobile 6 (1950)
Oldsmobile 8, Except Series 98 (1950-51)
Pontiac 6 & 8, All Models (1946-54)

►CHANGES, CAUTIONS, CORRECTIONS

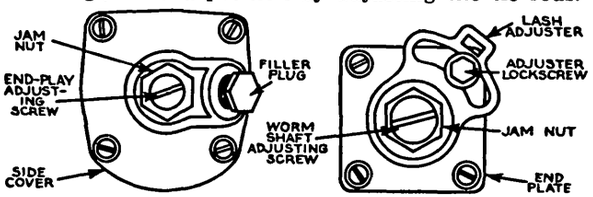
►*1953 PONTIAC PITMAN ARM IDENTIFICATION NOTE*—Power Steering and Standard Steering Pitman Arms are not interchangeable (Power Steering Arms ⅜" longer). Power Steering Arms have No. 5665954, Standard have 5663355 (forged on underside of rear of arm).

►*1953 PONTIAC HORN BLOWING ON ROUGH ROAD & STICKING HORN BUTTON CORRECTION*—Caused by horn button contact grounding on flat washer under steering wheel nut. Replace washer with new flat washer No. 5665807 (1/64" smaller diameter).

►**1946-48 Pontiac Deluxe—Installation of Ground Plate to correct complaints of Horn not operating or "shocks" when horn button depressed. Caused by misalignment of metal cup insert in hub so that no contact secured with coiled ground spring. Correct by installing two new ground plates, No. 509553, as follows: Remove sponge rubber ring, install two ground plates diametrically opposite each other with longer leg upright against hub, replace sponge rubber ring. NOTE—These ground plates will be used to service the coiled ground spring No. 507960.**

DESCRIPTION: Hour-glass type worm and double tooth roller of same design used on previous models.

ADJUSTMENT



ADJUSTMENT: Disconnect steering connecting rod from pitman arm. Torque pitman arm nut to 110-125 ft. lbs. Loosen steering post bracket to be sure it is not sprung. If misaligned, shim at steering gear housing-to-frame bolts, tighten bracket.

Roller Shaft Endplay: Tighten four side cover-to-housing bolts, loosen adjusting screw jam nut, turn steering wheel to end position, then tighten adjusting screw securely, using offset screwdriver. Back off adjusting screw until it is free, then again turn it in until screw can just be felt to be bearing against shaft. Keep screw from turning, tighten jam nut. Test for endplay. No endplay should be felt when attempting to move pitman arm in or out but arm should be free without bind when moved radially.

Worm Shaft Endplay: Tighten three bolts holding end plate to housing. Do not tighten adjuster lock bolt. Loosen worm thrust screw nut. With steering gear turned to end position, near but not against stops, tighten worm thrust screw to obtain a pull at steering gear rim as indicated in following table. Tighten lock nut.

Car Model	Worm Bearing Setting
Oldsmobile 1946-48	1-1½ lbs.
Oldsmobile 1949-51	½-⅞ lb.
Pontiac 1946-54	⅜-⅝ lb.

Worm & Roller Backlash: Disconnect drag link from pitman arm. Loosen lash adjuster lock bolt (in the slot through adjuster). Center the steering gear so steering wheel in straight ahead position. Tap lash adjuster plate lightly to turn it in direction of arrow until a pull is secured at steering wheel rim as indicated in following table. CAUTION—Lash adjuster plate should not be moved more than 1/16" (in relation to lock bolt) at a time and in no case should a tighter adjustment than maximum limits in table below be made as damage to gear may result). Tighten lash adjuster lock bolt securely. Check adjustment. Move steering wheel through entire travel right and left to check for tight spots. If tight spots found on both sides of central position, loosen lash adjuster lock bolt, tap lash adjuster plate opposite direction of arrow just enough to bring pull at tightest point between limits indicated in table. If tight spot only on one side of wheel center position, adjust gear for maximum pull (see table) through tight spot. Then with wheel in center of the high spot, remove wheel and reinstall it with spokes in straight ahead position (must not vary more than 5 degrees from horizontal when front wheels straight ahead). Reconnect drag link to pitman arm keeping steering wheel in straight ahead position and worm on high spot. Place wheels in straight ahead position by adjusting the tie rods.

SAGINAW WORM-AND-ROLLER TYPE ADJUSTMENTS

Car Model	Backlash Setting
Oldsmobile 1946-48	1¾-2¼ lbs.
Oldsmobile 1949-51	1½-2 lbs.
Pontiac 1946-54	1¼-1¾ lbs.

STEERING WHEEL POSITION: See Front Suspension Section for tie rod adjustment to correct intermediate steering arm position.

STEERING WHEEL & HORN RING OR BUTTON REMOVAL

Oldsmobile, All Models 1946-48.

Horn Button Removal—Insert sharp instrument under edge of button and pry upwards. Remove contact assembly after steering gear is removed.

Horn Ring Removal— Remove emblem by taking out two screws in outer edge. Remove two screws holding contact plate to ring and remove ring. Horn contact assembly is removed after steering gear removal.

Installation Note—When installing horn ring, see that contact plate guide is located in wheel puller holes and hook horn ring over lower extension of contact plate.

Steering Wheel Removal—Remove steering wheel retaining nut and install steering wheel puller Tool J-1262 with puller screws inserted in holes provided in steering wheel hub. Remove wheel.

Installation—Install wheel on steering shaft with spoke next to horn button connector opening straight down (with front wheel pointing straight ahead). Wheel retaining nut should be "staked" in position after tightening securely.

Oldsmobile 1949-51 (Except 1950-51 Series 98).

Horn Button Removal (Standard Wheel)—Button is held in position by means of three dimples on button retainer cup, inside steering wheel hub and the rubber ring in horn button. Insert a sharp instrument underneath adge of horn button and pry upward. Remove wheel to remove contact assembly.

Horn Button Removal (Deluxe Wheel)—Place palm of hand squarely on horn button, press firmly, and turn slightly in counter-clockwise direction. Remove horn button and rubber cushion. Remove wheel to remove contact assembly.

Steering Wheel Removal—Remove wheel retaining nut and install steering wheel puller Tool J-1262 with puller screws inserted into holes in wheel hub. Remove wheel.

Installation—Position car wheels straight ahead. Place steering wheel on steering shaft with center spoke pointing straight down on 1949 Models; and with mark on steering wheel hub and mark on end of steering shaft lined up in the straight up position on 1950-51 Models.

Pontiac 1946-48.

Horn Button Removal (Sounding Keys on Spokes). Disconnect horn wire from lower terminal on horn relay. Remove steering wheel cap by pressing on cap and tilting so a screwdriver can be inserted, then carefully pry off. Remove two screws, one at each end of trim strip, after which sounding key and trim strip can be removed. Remove rubber pad holding contact strip against connecting strip and remove contact strip. Remove wheel to remove rest of assembly.

Installation—Insert contact strip in spoke slot with dimple protruding down. Install rubber pad on top of contact strip and connecting strip. Install trim strip with sounding key in place, and attach with machine screw at rim end and the wood screw at hub end.

Steering Wheel Removal—See 1949-54 data below.

Pontiac 1949-54.

Horn Button Removal (Plain Button Type). Press down on one side of button which will cause opposite side to rise. Insert screwdriver and remove button.

Horn Button Removal (Ring Type). Disconnect horn wire at relay. Remove horn button cap by lifting out of wheel, then remove steering wheel nut and washer. Remove horn sounding ring assembly from steering gear.

Installation—Assemble horn ring assembly in steering wheel by tilting the top end down so that upper rubber spacer engages retaining lug in steering wheel hub, then pull lower end of ring down into position by sighting through cap hole. Particular care should be taken to locate the pilot hole in contact onto shoulder provided in the insulated connector. Install steering wheel nut and lockwasher and push button cap into position. Connect horn button wire.

Horn Ring Removal (1949-54 Deluxe Type)—Remove horn ring cap by turning slightly to left and lifting out. Remove steering wheel locknut and lift out horn ring assembly, then remove horn insulator and contact and spring assembly.

Steering Wheel Removal—Install puller J-452 (1946-48), J-3034 (1949-54) and remove wheel.

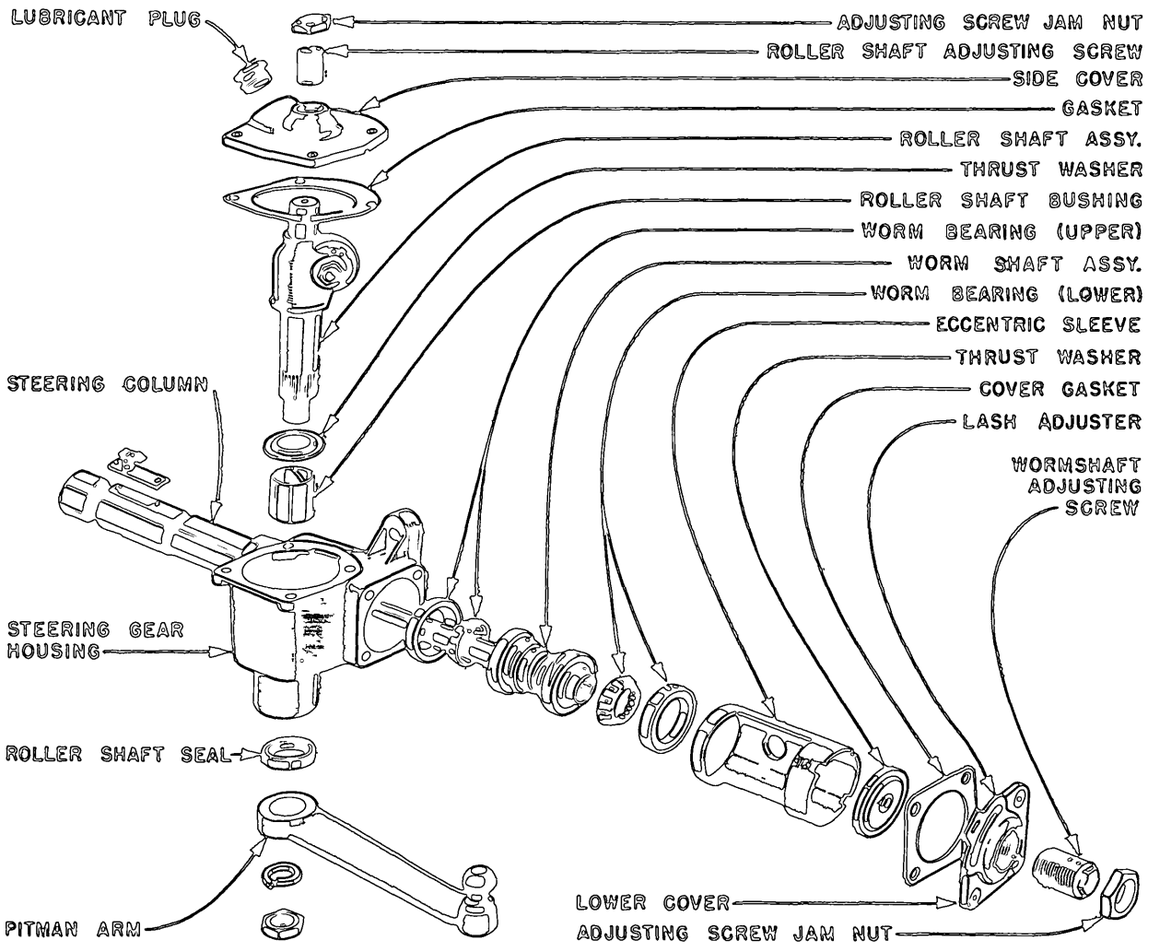
Steering Wheel Installation: Reverse removal procedure. Torque wheel nut to 25-30 ft. lbs. and locknut finger tight plus ¼ turn.

STEERING GEAR REMOVAL

►**STEERING GEAR REMOVAL NOTE** (Oldsmobile 1949 & Early 1950 Series 88 Cars): Remove left front

CONTINUED N NEXT PA E

SAGINAW WORM & ROLLER (Continued)



coil spring and swing lower control arm out of place in order to remove steering gear. Hole through cowl on later production cars has been enlarged so gear can be removed through driving compartment.

Pontiac, All Models (1946-48): Remove battery front compartment mat, clutch and brake pedal, toe plates and felts. Disconnect horn wire and remove steering wheel. Remove shift lever (use Tool J-1143), then remove pin which holds selector lever and idler to safety-shift lower support, allowing selector lever and idler to remain attached to selector rod. Remove screw at lower end of control shaft and slide off sleeve, control lever and idler lever, leaving the control shaft lever attached to shifter rod. Loosen instrument panel bracket clamp screw, then remove pitman arm, using Tool J-1025, and remove steering gear to frame bolts. Now remove the steering column to instrument panel attaching screw, slide bracket to upper support on steering column and pull gear out through hole in left fender skirt.

Pontiac, All Models (1949-54):

1. Remove steering wheel and horn button. If directional signal is used, disconnect wiring harness at multiple connector plug under instrument panel, (On 1949-52 Models, loosen directional signal housing clamp screw and lift signal assembly from steering column. Then remove steering column lower finish plate.
2. Roll back floor mat to right, and remove steering column and pedal upper and lower plates, felts, and felt retainer plate. Remove horn wire and neutralizer switch wire (Hydra-Matic). Remove gearshift lever except that on 1949-52 remove gearshift linkage as follows in Steps 3 through 5, then disconnect gearshift and selector rods from levers on steering column.
3. Remove selector lever pivot pin. This will allow selector lever and selector control idler lever to be removed from lower support together while remaining attached to transmission selector rod (adjustment is not disturbed this way). Remove control shaft return spring.
4. Remove bolt holding collar to control shaft and remove collar and shaft return spring clip. It is now possible to remove control shaft lever and control shaft idler lever together while remaining attached to transmission control rod (adjustment is not disturbed this way).
5. Remove two gear shift control upper support screws and remove control shaft, gear shift lever and upper support by pulling it into car. Remove nuts from U-bolt holding control shaft lower support to steering column and remove support.
6. On all cars, place supports under BOTH LOWER CONTROL ARMS so as to provide clearance for removing steering gear. Remove left side apron, then remove pitman arm from shaft using puller Tool J-1025. Loosen three bolts holding steering gear to frame, then remove two bolts, leaving the front upper bolt to support steering gear.
7. Remove bolts holding steering column lower bracket to upper bracket on instrument panel and also remove rubber grommet.
8. Remove remaining steering gear housing to frame bolt and remove steering gear by bringing it down through floorboard and over steering linkage toward right front wheel. If car is equipped with NO-ROL, it will be necessary to remove steering gear by bringing it up through floorboard moving upper end toward left front door and passing pitman arm shaft through between pedals. In this case Step 7 above should be performed after removing the three steering gear to frame bolts.

NOTE—Be sure to save shims found between frame and housing and re-install in same position.

SAGINAW WORM & ROLLER STEERING GEAR

STEERING GEAR OVERHAUL

Disassembly: Remove pitman arm using puller No. C-47. Remove side cover plate from housing and take out pitman shaft, then loosen "jam nut" and back out worm shaft adjusting screw from end of worm shaft. Remove endplate from housing and push worm and shaft assembly down through bottom of housing, removing eccentric sleeve, worm and bearings.

Inspection and Cleaning: Wash all parts in clean solvent and inspect for wear, pitting, or roughness.

Reassembly: Assemble two tapered roller bearings on worm shaft and eccentric sleeve over bearings. Put lower thrust washer in place inside eccentric sleeve to hold bearings in place. Start worm shaft adjusting screw into endplate, then install endplate on housing and attach with four capscrews. (NOTE—Worm shaft adjusting screw should be screwed in just enough at this time to hold bearings in place. Proper adjustment will be made later). Slide pitman arm shaft in place and attach side plate to housing. Install endplay adjusting screw and locknut.

Testing & Adjusting on Bench: Secure steering gear in vise and place steering wheel on shaft. Turn steering gear from one extreme to opposite to make certain there are no unusual binds. Adjust steering gear as outlined under ADJUSTMENT above.

STEERING GEAR INSTALLATION

Pontiac, All Models (1949-54):

1. Install steering gear assembly in car following same path used for removal.
2. Install top front steering gear housing to frame

CONTINUED ON NEXT PAGE

SAGINAW WORM & ROLLER (Continued)

bolt with lockwasher finger tight. ***(CAUTION—BE SURE TO INSTALL SHIMS WHICH WERE FOUND BETWEEN STEERING GEAR HOUSING AND FRAME ON REMOVAL).*** Install rubber grommet on steering column.

NOTE—On 1949-52 Hydra-Matic Cars install gearshift shaft and indicator assembly.

3. Install steering column lower bracket, bolts and lockwashers on upper bracket at instrument panel. Tighten bolts snugly but not to final tightness. Install two remaining steering gear housing to frame bolts with plain and lockwashers. Tighten all three housing to frame bolts.

4. Check for correct shimming of steering gear housing to frame by seeing if steering column aligns with bracket when bracket bolts are loosened. NOTE—If misalignment exists, it will be necessary to change steering gear housing to frame shims to correct alignment. (If steering gear alignment is satisfactory, tighten steering column bracket bolts).

5. Install pitman arm on pitman shaft. Make sure lockwasher is in good condition and is installed under pitman shaft nut. Tighten nut to 110-125 ft. lbs. Install left side apron. Install gearshift linkage. On 1949-52 models proceed as in Step 6.

6. Install steering column and pedal upper and lower plates, felts and felt retainer plate. Install control shaft, gearshift lever and upper support by sliding assembly down into place from inside car. Insert upper support screws but do not tighten. Coat hole in control shaft lower support with Lubriplate and slip lower support over control shaft and secure on steering column by installing U-bolt, nuts and lockwashers. Tighten control shaft upper support screws and install column lower finish plate.

7. On 1949-52 Models, install direction signal on steering column, tighten clamp screw. On all models, install direction signal lever and connect direction signal and horn wiring under instrument panel.

8. Install steering wheel. See that wheel spokes are in straight ahead position when steering gear is on high point of cam with mark on steering shaft up and wheels are in straight ahead position (see Adjustment). Tighten wheel nut to 25-30 ft. lbs. and locknut finger tight plus ¼ turn. On 1949-52 Models proceed as follows in Steps 9 and 10.

9. Install control shaft lever and idler lever, return spring clip, lockwasher, and collar on control shaft by properly positioning these parts and inserting retaining bolt and washer and tightening.

10. Install control shaft return spring. Install selector control lever and selector control idler lever by positioning the selector control lever in collar and inserting lever pivot pin. Coat collar surface contacting selector lever with Lubriplate.

11. On all models, connect horn wire and neutralizer switch (Hydra-Matic).

STEERING LINKAGE: *See "Steering Linkage."*

SAGINAW BALL BEARING WORM & NUT

Buick, All Series (1946-55)
Cadillac V8, All Series (1946-53)
Cadillac, Series 86 Only (1954)
Chevrolet, Pass. Cars (1955)
Chevrolet, Trucks (1946-55)
Oldsmobile, Series 98 (1950-51)
Oldsmobile, All Series (1952-55)
Pontiac, All Models (1955)

►CHANGES, CAUTIONS, CORRECTIONS

►*1954 BUICK STEERING COLUMN RATTLE CORRECTION:* Effective May 1954 production, a new anti-rattle spring, Part No. 561362, is being installed to eliminate shift tube rattles in steering column. This new, heavier spring, may be installed on earlier 1954 cars where these shift tube rattles have been noted.

►*1955 BUICK STEERING COLUMN RATTLES (Caused By Shift Control Linkage):* An anti-rattle spring, Part No. 1169208 has been released for service to eliminate this condition. To install spring, remove steering wheel and horn ring. Loosen directional signal wiring at lower steering column and remove switch and housing. Remove three bolts from mast jacket to control lever housing support. Place control lever in "Park" position and remove control lever. Remove support and install spring with large end of spring around control lever housing and small end of spring hooked around edge of mast jacket. *NOTE*—On some cars it may be necessary to remove die flash on control lever housing in order to install spring.

►*1955 OLDSMOBILE STEERING COLUMN RATTLE CORRECTION*—Check steering column upper bushing for looseness. Make sure that the three upper bearing retainer screws are tight before replacing bushing.

DESCRIPTION: Recirculating ball nut type. Nut mounted on worm and driven through steel balls which circulate in helical grooves in both worm and nut. Return guides attached to nut serve to recirculate the two sets of balls through grooves. Gear teeth on nut mesh with sector teeth on cross-shaft so that cross-shaft (and steering gear pitman arm) rotate as steering wheel is turned causing nut to move up and down.

ADJUSTMENT

ADJUSTMENT: Adjust in following sequence.

Steering Gear Alignment: Before any adjustments are made to steering gear check for binding at frame bracket mounting bolts and at instrument panel bracket. Note clearance between steering gear and frame or bracket. If clearance exists loosen mounting bolts to permit steering gear to shift on frame to align with column bracket, or shim bracket.

Buick Note—Steering gear is trunnion mounted on bracket so that it is free to swing in both directions when bracket mounting bolts are loosened. Front lower bolt serves as pivot and other three bolts pass through slotted holes in frame bracket and side rail to provide for vertical adjustment. Clamps bear against cylindrical extension of housing so that it can be turned in clamps for sideways adjustment.

Worm Shaft Endplay: Disconnect pitman arm from steering shaft or rod, check tightness of pitman arm nut with 18" wrench. Loosen pitman shaft adjusting screw locknut, back off adjusting screw a few turns. With spring scale at rim of steering wheel, measure pull required to keep wheel in motion at about 30° off center. Pull should be as shown in table below. If not, loosen lock at end of worm shaft and turn adjusting screw required amount with Tool KMO-695 to bring spring pull within limits. When adjustment correct, retighten locknut, recheck preload.

Car Model	Worm Bearing Setting
Buick	7/8-1 1/8 lbs.
Cadillac (1946-51)	ℂ 1-1 1/4 lbs.
Cadillac (1952-53)	1-1 1/8 lbs.
Cadillac (1954)	1-1 1/4 lbs.
Chevrolet Pass. Car	3/8-5/8 lbs.
Chevrolet Truck	1-1 1/2 lbs.
Oldsmobile	1/2-7/8 lbs.
Pontiac	3/8-7/8 lbs.

ℂ— 1 1/8-1 1/2 lbs. on cars driven less than 1000 miles.

Pitman Shaft Endplay (Nut & Sector Mesh Adjustment): Turn wheel to center position with nut on high point of gear. Tighten pitman shaft adjusting nut on lower side cover until pull at wheel rim required to turn wheel through center high point as measured on scale at wheel rim, is correct (see table below), hold adjusting nut, tighten locknut.

Car Model	Backlash Setting
Buick	2-2 1/4 lbs.
Cadillac	ℂ 1 1/2-2 lbs.
Chevrolet Pass. Car	7/8-1 1/2 lbs.
Chevrolet Truck	2-2 1/2 lbs.
Oldsmobile	1 1/2-2 lbs.
Pontiac	1-2 lbs.

ℂ—2-2½ lbs. on cars driven less than 1000 miles.

►*ADJUSTMENT CAUTION: This is push-pull type adjustment and controls pitman arm shaft endplay as well as gear mesh.*

STEERING WHEEL POSITION: Buick—With steering wheel properly installed, front wheels in straight ahead position and steering gear on "high spot", steering wheel lower spoke should be in a vertical position.

Buick (1948) Steering Wheel Height—Wheel cannot be raised but may be lowered approximately 11/16" by installation of two special spacers between steering column bracket and lower flange of instrument panel (requires use of longer bolts). Spacers are No. 1321253, bolts are No. 1325016—4 3/16" long (Right Side 40, 50; Left Side 70), No. 1325013—4 11/16" long (Left Side 40, 50), No. 1324888—3 11/16" long (Right Side 70).

Buick (1949) Steering Wheel Height—Series 50 wheel can be raised approximately 11/16" by substituting Series 70 steering column bracket and spacers and column-to-instrument panel grommet. Series 70 wheel can be raised approximately ½" by removing the two 3/16" spacers located between steering column bracket and instrument panel (this may cause some buckling

CONTINUED ON NEXT PAGE

SAGINAW WORM & NUT (C ntinued)

of steering column-to-instrument panel grommet). Series 70 wheel can be lowered approximately 11/16" by substituting Series 50 steering column bracket, bracket bolts, and steering column-to-instrument panel grommet.

Buick (1950) Steering Wheel Height—Series 40-50 steering wheels may be raised or lowered, Series 70 wheel can only be lowered, from standard height. Alteration is effected by changing number of spacers between steering column bracket and support bracket on instrument panel, and by substituting longer bolts and different steering column bracket when required See table below

Adjustment	Bracket	Spacer	Bolt
Series 40 (Early)			
Lower 1/2"	Production	(2) 1332163	(2) 107241
Lower 3/4"	Production	(3) 1332163	(2) 107241
Raise 3/8"	1322944	None	Production
Raise 3/4"	1322950	(1) 1339597	Production
Series 40 (Later), 50			
Lower 1/4"	Production	(3) 1332163	(2) 107241
Raise 1/2"	Production	Remove all	Production
Raise 7/8"	1322944	Remove all	Production
Series 70			
Lower 1/2"	1323729	None	Production
Lower 1"	1323729	(2) 1332163	107241

Buick (1954-55) St ring Wheel Height—Distance from column bracket to lower surface of instrument panel for normal steering wheel height is 5/8-3/4" (Series 40 & 60); 3/8-1/2" (Series 50 & 70). Height of steering wheel may be set as much as ¾" above or below normal height to suit drivers needs. S *"Buick Note" under "Adjustment" above.*

Cadillac—Position wheel so middle spoke is vertical on three spoke types or both spokes horizontal on two spoke types with nut on high center point of worm and front wheels pointing straight-ahead. Steering wheel and shaft are notched.

Ch vrol t Pass. Cars & Trucks—With steering wheel properly installed, front wheels in straight ahead position, and steering gear on "high spot", steering wheel mark on end of wormshaft should be at top of shaft and aligned with mark on steering wheel.

Ch vr l t Pass. Car St ering Wheel & Mast Jacket Cl aranc—Gap between top edge of direction signal housing and bottom outer edge of steering wheel should be 1/32-9/64".

Oldsmobil—With marks on steering wheel and hub aligned, center spoke should be in a vertical position (1950-52), spokes should be horizontal (1953 & Later), when front wheels are in a straight-ahead position and steering gear is on "high spot".

Oldsm bil Steering Whe l & Mast Jacket Clearance (1953 & Later)—Clearance between lower edge of steering wheel and direction signal housing should be 1/8-3/16"

Pontiac—With steering wheel properly installed, front wheels in straight ahead position and steering gear on "high spot", steering wheel spokes should be horizontal and mark on steering shaft should be at top.

STEERING WHEEL & HORN BUTTON AND RING REMOVAL & INSTALLATION

NOTE—Proceed as follows for each model Reverse removal procedure for installation except as noted.

Buick, All Models:

Horn Button Removal (Solid Spoke Type Wheel)—Pry button carefully out of wheel.

Horn Button Removal (Flexible Spoke Type Wheel)—Pry off monogram and bezel assembly, take out mounting screws, remove button operating ring.

Steering Wheel Removal—Remove horn button or operating ring and replace steering wheel nut, leaving it backed off several turns. Set direction signal switch in "OFF" position Install Puller J-1120 (1946-47), J-1566 (1948-54), J-3274 (1955) and pull wheel back to nut Remove puller, nut, and steering wheel When reinstalling wheel *be sure direction signal switch is in "OFF" position.*

Cadillac, All Models 1946-51:

Horn Button Removal—Hold wheel stationary, depress button and turn counter-clockwise to release. Lift button out and remove horn button retainer ring and spring On Special Model, remove horn ring, take out three screws holding retainer and rubber gasket to horn ring and remove parts

Steering Wheel Removal—Remove steering wheel retaining nut and install steering wheel puller Tool J-1859 and remove wheel

Cadillac, All Models 1952-53, Series 86 1954:

Horn Button & Horn Ring Removal—Disconnect horn wire from terminal at lower end of steering column, depress horn button, turn counter-clockwise until locking ears are released, remove button and horn button spring. Remove steering wheel nuts, then remove horn ring retainer, cushion, and horn ring.

Steering Wheel Removal—Remove horn button, then wheel nut. Install Puller J-1859 and remove wheel.

Chevrolet Pass. Cars:

Horn Button Removal—Pry off horn button or ornamental cap.

Steering Wheel Removal—Remove horn button or ornamental cap and remove steering wheel nut and washer from end of steering shaft. Remove wheel with Puller J-2927-A.

Chevrolet Truck:

Horn Button Removal—Insert screwdriver between button and wheel, gently pry button out.

Steering Wheel Removal—Remove steering wheel nut, install Puller J-1618 (1946-51), J-2927A (1952-55), remove steering wheel.

Oldsmobile, Series 98, 1950-51:

Horn Button Removal—Place palm of hand squarely on horn button, press firmly and turn slightly in counter-clockwise direction. Remove horn button and rubber cushion. Remove wheel to remove contact assembly.

Installation Note—Make sure that both horn button cushions are in place. Upper cushion should be installed flat face upward, and the three projections on opposite end should lie on horn contact retainer depressions.

Ste ring Whe l Removal—Remove wheel retainer nut and install steering wheel puller Tool J-1262 with puller screws inserted into holes in wheel hub Remove wheel

Oldsm bil , All Series 1952-55: Disconnect horn wire at relay, then proceed as follows:

Horn Button Removal (1952 DeLuxe)—Same as 1950-51 Series 98

Horn Button Removal (Std.)—Insert sharp instrument underneath edge of horn button, pry button upward and out. Remove steering wheel nut, then contact assembly.

Horn Ring Removal (DeLuxe)—Two spring clips on ends of horn button engage horn ring hub. To remove horn button use small screwdriver to relieve spring tension on one end, lift button from seat. Remove wheel nut, then contact plate, horn ring.

Steering Wheel Removal—Install puller J-1262, remove steering wheel.

Pontiac, All Models:

Horn Button Removal—On standard steering wheel, press down on one side of horn button and insert screwdriver under other edge and pry up. On deluxe steering wheel, rotate horn ring button counter-clockwise.

Steering Wheel Removal—Remove locknut, nut, washer, horn ring, horn insulator and contact assembly. Remove steering wheel with Puller J-3044.

STEERING GEAR REMOVAL & INSTALLATION

Buick, All Models 1948-49 (Removal): 1) Disconnect pitman arm from steering tie rod by unscrewing tie-rod plug until bearings will release ball stud

2) *On Series 70 only,* remove air cleaner assembly Disconnect fuel and vacuum lines from carburetor and move them out of the way.

3) Remove windshield wiper and bracket.

4) Disconnect transmission selector rod from selector control lever and unhook anti-rattle spring Disconnect upper shift rod from control shaft lower lever Disconnect clutch linkage and anti-rattle spring from shift idler lever pin

5) Disconnect wires from horn cable connector back-up light switch and neutral safety switch (Dynaflow cars only). Pull speedometer cable from clip and then remove horn cable connector from column jacket to avoid damage during removal of gear.

6) Disconnect one end of cross brace at cutout in cowl and swing brace to one side

7) Remove dash insulator retainer and steering column pad Pull back floor mat and remove pedal plate attached to toe panel.

8) Remove steering wheel and the upper bearing spring and spring seat. Remove gear shift control lever and signal switch control lever Remove front seat cushion

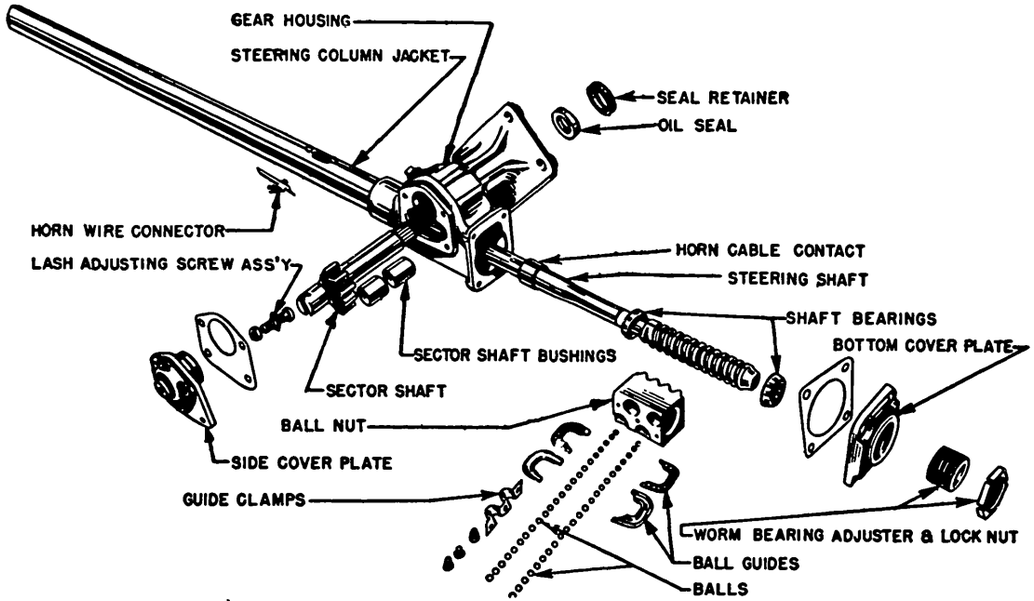
9) Disconnect direction signal switch wires from terminals on instrument panel

10) Remove steering column bracket On 1949 models remove the steering column to instrument panel grommet

11) Remove steering gear to frame bolts and clamps, then carefully support steering column to avoid damaging column jacket. Move gear assembly to rear as far as possible, turn assembly over so that pitman arm is uppermost, then lift forward end up toward engine and fender and move forward to remove gear assembly from car. It is advisable to have a helper guide the column

CONTINUED ON NEXT PAGE

SAGINAW WORM & NUT (C ntinued)



jacket and signal switch housing through cutout in cowl panel to avoid damaging finish of these parts.

Buick, 1950-53: Steering gear removal is the same as for 1948-49 models except for the spacers located between bracket and support on instrument panel.

Buick 1954-55 (Removal): Disconnect transmission shift rod from control shaft lower lever & selector lever (synchro-mesh only), then loosen bolt in clamp which secures column jacket to short tube in gear housing. Disconnect and remove horn cable connection from steering column jacket. Move front seat all the way back and cover seat and back. Cover steering column jacket with masking tape. Remove steering wheel and the upper bearing spring and spring seat. Cover horn contact and threaded end of steering shaft with masking tape. Remove signal switch and transmission shift control levers. Disconnect wires from neutral safety switch and disconnect wires (signal) from fuse block. Detach rubber insulator retainer from dash mat and pull it a foot up on column jacket. Remove jute column pad. Measure and record vertical distance between column jacket and lower surface of instrument panel so column can be reinstalled in same position. This dimension affects steering wheel height, which may have been changed from normal height to suit driver of car. Remove bolts holding cap to steering column bracket, disconnect bracket from instrument panel, then pull upward on column jacket to free it from steering gear. Remove starter splash pan from car frame. Remove steering gear-to-frame lower bolts and clamps, then loosen upper bolts enough so that gear can be tilted sideways to provide room for pitman arm puller. Remove nut and lockwasher, then remove pitman arm from pitman shaft, using suitable puller. With another man inside car to guide steering column and prevent damage to column jacket and front seat, carefully lift steering gear assembly up and forward out of engine compartment, leaving column jacket assembly in body.

Cadillac, All Models 1948-53, Series 86 1954 (Removal): Raise front of car so wheels are 6" off floor. Remove steering wheel and anti-rattle spring under steering wheel. On 1951 and later models, remove upper and lower column covers. Remove horn wire from terminal at lower end of steering column. Loosen clamp holding lower steering jacket to upper jacket. Tap clamp down over lower jacket. Disconnect steering connecting rod at pitman arm and remove bolts holding steering gear to frame side rail (On 1951 and later cars remove any shims found at upper housing mounting bolts). Strike housing firmly a few times with a lead hammer to drive lower steering column jacket down out of upper jacket. Remove steering gear, lower jacket, and steering column from below car.

Ch vrolet Pass. Car (Removal): Disconnect all electrical connections and remove the back-up light switch (where installed), from mast jacket *(NOTE—*A combination Neutral Safety & Back-up Light Switch is used on Powerglide models). Remove two rubber cover fasteners from inside of dash panel at mast jacket opening. Pry off horn button and remove steering wheel. Slide rubber seal away from covers, and remove lower

SAGINAW BALL BEARING WORM & NUT STEERING GEAR

cover retaining screw and washer and lower and upper covers. On Powerglide models only, disconnect ends of indicator rod from indicator lever and shifter tube and remove rod. Remove neutral safety switch, and remove transmission control selector plate from lower end of steering column. On all models, remove clamp bolt from dash panel attaching bracket. Disconnect transmission control linkage from shift levers at swivels and remove swivels. Remove clamp and rubber shims from bottom of instrument panel. From inside car, pull mast jacket assembly off steering shaft, rotating as necessary to clear dash clamp. Work shift levers through seal by stretching seal to clear levers. Remove pitman arm from sector shaft using Puller J-5504 (see Puller J-5504 Rework for use on Early Cars, below). On Power Steering models, remove the generator-to-support and generator brace bolts and move generator and pump assembly out of position (without disconnecting hoses) to obtain clearance to remove steering gear assembly. Remove nuts and lockwashers from steering gear to frame bolts, shims (where installed), and steering gear. Remove the four felt seals from mainshaft of steering gear assembly.

►**Puller Tool J-5504 Rework (For use on Early Cars):** Grind off 5/16" lip of tool to permit installation between pitman arm and gear housing.

Installation—Reverse the removal procedure and note "Steering Wheel Position" and "Steering Gear Alignment" above.

Chevr let Trucks 1946-53 (Conventional Models):

1) Remove horn button and steering wheel. Remove seat cushion.

2) Remove steering mast jacket to instrument panel bracket screws, bracket and grommet. Disconnect horn wire and remove cover plate from steering mast jacket.

3) Remove two sheet metal screws attaching steering mast jacket toe board grommet and seal to toe board plate. Slide toe board grommet and seal up mast jacket and remove toe board plate.

4) Disconnect pitman arm using Tool J-1025, and remove all steering gear housing to frame mounting bolts. From inside cab remove three bolts attaching rear of left front fender skirt to toe board, and remove six bolts attaching fender skirt to ledge.

5) Remove fender to dash brace rod and disconnect horn wire from horn. Working under fender, pry rear of fender skirt forward and outward until it rests on the outside toe board flange.

6) Working over fender, pry fender skirt outward along frame at steering gear housing to provide clearance between frame and fender skirt.

7) Slide steering gear assembly slightly upward toward toe board. Then rotate until attaching flange is up. Raise slightly and slide forward removing assembly over front of front fender.

Chevrolet Trucks 1954-55 (Conv nti nal Mod ls):

1. Disconnect horn wire, remove wire retainer from steering mast jacket. Remove horn button and steering wheel, then remove steering mast jacket-to-instrument panel bolts, bracket and grommet.

2. On ½ and ¾ ton trucks, disconnect gearshift upper control shaft support from mast jacket, then separate upper steering control shaft from lower shaft by removing lower bolt from both shaft clamps.

3. Remove sheet metal screws attaching steering mast jacket toe-board grommet and seal to toe-board plate. Slide toe-board grommet and seal up mast jacket, remove toe-board plate.

4. On Forward Control models, hoist front end of vehicle, remove mast jacket opening cover

CONTINUED ON NEXT PAGE

SAGINAW WORM & NUT (C ntinued)

5. On ½ and ¾ ton trucks, remove bolts and clamp attaching gearshift control housing to steering column mast jacket
6 Disconnect pitman arm, using puller J-1025, then remove gear housing-to-frame mounting bolts
7. On Forward Control models, remove steering gear by moving forward, down, and out of vehicle
8. On models other than Forward Control, from inside cab remove three bolts attaching rear of left front fender skirt to toe-board, remove six bolts attaching fender skirt to fender ledge, then remove fender-to-dash brace rod, disconnect horn wire.
9. Working under fender pry rear of fender skirt forward and outward until it rests on outside toeboard flange, then, working over fender, pry fender skirt outward along frame at steering gear housing to provide proper clearance between frame and opening in fender skirt
10. Slide steering gear assembly slightly upward toward toe-board, then rotate until attaching flange is up Raise slightly and slide forward, removing assembly over front of front fender

Ch vr l t Trucks, Cab-Over-Engine & Low-Cab-Forward Mod ls (R m val):

1. Remove steering wheel and disconnect dash mounting bracket Remove left hand floor pan and steering column grommet Disconnect horn wire Remove fender skirt bolts and remove skirt
2. Remove pitman arm using Tool J-1025, and remove steering gear to frame mounting bolts
3. Move gear back to clear radiator grille side baffle assembly It will then be possible to drop gear down through fender skirt opening, pulling the steering column through opening in floor

Oldsmobile, All S ri s (R moval):

1, Disconnect horn wire at relay, remove steering wheel assembly Remove floor mat, and remove mast jacket cover attaching screws Loosen upper and lower mast jacket clamps
2. Hoist car and remove engine filler plate. Remove pitman arm and steering gear to frame mounting bolts Remove steering gear by pulling it down and out of mast jacket

Pontiac (R moval):

1. Remove steering wheel If car is equipped with power brakes, remove power brake unit. Disconnect direction signal wires at connector under instrument panel Remove signal lever
2. Remove steering column lower finish plate and remove steering column and pedal plate, felts, and retainer plate
3. Disconnect horn wire and neutralizer switch Remove gearshift lever and disconnect selector rods from levers on steering column
4. Raise car on hoist and remove engine side apron Remove pitman arm with Puller J-5504 and remove steering gear housing to frame bolts, leaving the forward bolt in place to support steering gear Remove steering column lower bracket to upper bracket bolts
5. Remove remaining steering gear housing to frame attaching bolt and remove steering gear by bringing it through floor board and over steering linkage toward right fender Save shims found between housing and frame

STEERING GEAR OVERHAUL

STEERING GEAR OVERHAUL: Disassembly—With steering gear removed, remove the pitman arm with a suitable puller (CAUTION—Do not drive pitman arm from cross shaft as damage to worm and ball nut will result) Loosen adjusting screw lock nut, then remove housing side cover with pitman shaft attached, remove gasket Separate pitman shaft from side cover by unscrewing the adjusting screw Loosen lock nut and back off worm thrust bearing adjuster several turns, then remove housing end cover and gasket Remove lower thrust bearing, steering shaft, and upper bearing from housing (NOTE—Manufacturer recommends that ball nut NOT be disassembled, however, if it is necessary to disassemble ball nut, proceed as follows) Remove ball return guide clamps and guides from ball nut, turn ball nut over to remove balls (Caution—Hold shaft and ball nut assembly over a wide pan while disassembling to retain all balls It is very important that balls be counted, and the same number of balls reinstalled when gear is assembled) Remove ball nut from steering shaft

Reassembly: (Ball Nut)—Place worm shaft flat on bench and slip nut over worm with ball guide holes up and shallow end of rack teeth to left from steering wheel position Align grooves in worm and nut by sighting through guide holes Count out one-half the number of balls removed at disassembly, and drop them into one of the guide holes while turning the worm gradually away from the hole, until guide hole is full from bottom of one guide hole to the bottom of the other (in cases where balls are stopped by end of worm, hold down the balls already dropped into hole and rotate worm back and forth) Lay one-half of guide, groove up, on the bench and place remaining half of balls in it These remaining balls should fill it Close this half of guide with other half Hold both halves of guide together and plug each end with vaseline to hold balls in place Push guide into holes of nut, completing one circuit Repeat same operation with other circuit Then assemble ball guide clamp to nut with lockwashers under clamp screws and tighten screws securely

Steering Gear—Place worm shaft and nut assembly into housing and place upper roller bearing over worm shaft Place new housing end cover gasket over end of worm shaft, make sure horn wire is through opening in mast jacket, then slide housing end cover over worm shaft and assemble it to housing Install lower roller bearing, worm bearing adjuster and lock nut in lower end of housing Assemble lash adjuster with shim in slot in end of sector shaft Check end clearance which should not be greater than .002" Adjust end clearance with shims as required Start sector shaft pilot into bushing in side cover Then, using a screwdriver through hole in cover, turn lash adjuster in counter-clockwise direction to pull sector shaft pilot into its bushing as far as it will go Rotate worm shaft by hand until ball nut is at center of travel Place a new gasket on side cover, then push side cover assembly including sector shaft into place After making sure there is some play between rack and sector teeth, assemble and tighten side cover bolts Install steering gear in car (see instructions below), and adjust steering gear See ADJUSTMENTS above

STEERING GEAR INSTALLATION

Buick, 1948-53:

1. Install steering gear assembly by reversing sequence for removal and note following
2. Leave frame bracket bolts loose until steering column bracket and any original spacers are installed Center steering column in cutout in dash panel and tighten the column bracket bolts, then tighten the frame bracket bolts
3. Connect signal switch wires at fuse block
4. Before installing transmission control lever, coat inner end and the socket in selector rod (synchro-mesh) or stop pin (Dynaflow) with Lubriplate If a new bearing is installed on control lever, the large diameter of bearing must be toward lever knob. During installation of lever be careful to draw housing nut tight so that shoulder in nut will bear against bearing seat flange, lock seat in place
5. Install steering wheel with location marks in line (See Steering Wheel Installation above)

Buick, 1954-55:

1) Install steering gear assembly by reversing removal procedures and note the following

2) Place control shaft return spring over lower end of control shaft before inserting steering shaft into control shaft

3) Measure vertical distance between column jacket and lower surface of instrument panel See "Steering Wheel Height" under STEERING WHEEL POSITION

4) When connecting intermediate rod to pitman arm, tighten end plug to 20-25 ft lbs then back off 2±1/8 turns and install cotter pin

5) After installation of horn operating ring adjust steering column jacket on tube of gear housing as required to provide a clearance of .150" between operating ring and signal switch housing

6) Install steering wheel with marks in line

Cadillac, All Models 1948-53, Series 86 1954:

Upper end of lower steering jacket must be smooth and free from burrs and lower end of upper jacket smooth on the inside Make sure cross-over spring, seat and washer for cars with synchro-mesh transmissions, are in place in lower jacket Then slide steering gear assembly up inside upper jacket Use a lead hammer to drive gear housing up until bolt holes in steering gear housing line up with hole in frame side bar Install three mounting bolts and tighten lower bolt Slide steering jacket clamp up onto upper jacket and tighten clamp bolt Align steering gear by checking space between rear housing and frame side bar and install proper thickness shims to fill gap at two rear mounting screws If there is no space at rear, loosen the front screw and tighten the two rear screws Check space at front of gear and add shims to fill gaps at this point Tighten and torque three mounting screws to 40-45 ft lbs Connect pitman arm to steering connecting rod, turning end nut up tight and backing it off ½ to ¾ turn Install horn wire on terminal on lower steering jacket Install steering wheel

Chevrolet Passenger Cars, 1955:

1) Place the four felt seals over mainshaft and slide against steering gear housing Insert end of mainshaft through dash panel opening and position steering gear

CONTINUED ON NEXT PAGE

SAGINAW WORM & NUT (Continued)

assembly on frame. Install bolts, lockwashers and nuts through bracket. *NOTE*—Shims may be placed between steering gear and frame to center steering shaft in dash panel opening.

2) Connect pitman arm to pitman shaft. Install mast jacket and shifter tube assembly as described below. Install generator, and pump assembly on Power Steering models.

3) Slip assembled mast jacket over steering shaft, rotating as required to provide clearance for the shifter levers and other projections at dash panel. *(NOTE*—Rubber seal at dash panel must be stretched to clear shifter levers).

4) Position upper mast jacket clamp with upper and lower rubber shims installed over retaining bolts so that key in clamp engages keyway in bottom of mast jacket and clamp is centered in dash panel opening. Install clamp washers and nuts and tighten nut just enough to hold key in keyway and still permit mast jacket to be moved along steering shaft.

5) Install steering wheel, horn mechanism and horn button or ornamental cap, aligning steering wheel with mark on end of steering shaft.

6) Grasp mast jacket assembly and pull assembly back along steering shaft toward steering wheel. Locate assembly 1/16" from steering wheel (use feeler gauge between top edge of direction signal housing and bottom outer edge of steering wheel). Tighten clamp nuts below instrument panel.

7) Install dash panel attaching bracket clamp bolt, washers and nut.

8) With shift lever in neutral, check to see if steering gear shaft is centered in mast jacket assembly. If shaft is not centered, loosen dash panel bracket clamp bolt and two lower bracket retaining bolts. With shimming tool or drill rods installed (rods evenly spaced around steering shaft), securely tighten first the upper clamp bolt, then the two lower bracket bolts.

9) Connect transmission control rods to shifter levers. On Powerglide models, install the transmission control selector plate. With shift lever in neutral position, install back-up light and neutral safety switch.

10) Position rubber seal and cover to dash panel and install upper fasteners. Connect horn wire, direction signal, back-up light and neutral safety switch wiring.

Chevrolet Trucks, Conventional Models, 1946-53:

1. Place steering gear assembly back in vehicle and align housing and bracket to frame. Install all mounting bolts and tighten securely.
2. Push fender skirt in place and start all bolts in position (do not tighten at this time). After all bolts are in place start tightening bolts from front to rear. Assemble pitman arm, lockwasher and nut, and tighten securely. ***CAUTION—Do not pound on pitman arm as this may cause internal damage.***
3. Install toe board plate. Attach a piece of wire to end of horn wire that enters the mast jacket, then push the horn wire inside the opening in the jacket. Slide jacket toe board seal and grommet over jacket. Place floor mat in position, making sure edge of opening for jacket is between grommet and seal.
4. Pull horn wire through opening in mast jacket and install cover plate.
5. Install jacket to instrument panel grommet, bracket and screws (make sure it is not necessary to force jacket in place to install clamp). If necessary, adjust dash mounting bracket to fit, and tighten.
6. Install steering shaft upper bearing spring seat (with flared end up) and spring. Install steering wheel and insert horn button insulator, contact and spring assembly in opening provided in steering wheel hub, making sure the contact brush (solid end) is in the downward position. Install contact cup, positioning the tang on the lower side.
7. Install steering wheel washer and nut and tighten. Install horn button and connect horn wire.

NOTE—On models where it was necessary to remove clamp holding vacuum lines, align the vacuum lines to their proper position and install clamp.

Chevrolet Trucks, Conventional Models, 1954-55:

1) To install steering gear assembly, reverse removal procedures and note the following.

2) Torque pitman arm nut to 100 ft. lbs., then tighten to next notch for insertion of cotter pin. **Do not pound on pitman arm.**

3) On ½ and ¾ ton, install gearshift control housing on mast jacket using caution to locate dowel on housing in slot of mast jacket. Do not tighten clamp bolts. Check clearance between gearshift lever and gearshift upper control shaft support. Clearance as measured from lower edge of gearshift lever to top of upper support should be 3/32" to 1/8". To correct this clearance, remove upper bolt from upper and lower control shaft clamp and remove two screws holding upper support to steering gear housing and remove upper control shaft assembly. Screw upper support up or down to get required clearance. Replace upper control shaft, tighten clamp bolt, and replace upper support screws.

4) Clearance between end of gearshift lever and lower edge of steering wheel rim should be 2 13/16"±1/8" on all models except ¾ ton forward control, which should be 2 9/16"±1/8". To correct this clearance, loosen two gearshift control shaft and housing assembly clamp bolts and move housing assembly with upper and lower control shafts and gearshift lever up or down to obtain necessary clearance. Tighten housing assembly clamp bolts.

Chevrolet Trucks, Cab-Over-Engine & Low-Cab-Forward Models:

1. Place steering assembly back in vehicle and align housing and bracket to frame. Start all bolts and tighten securely. Replace fender skirt.
2. Assemble pitman arm, lockwasher and nut and tighten securely.
3. Install mast jacket to instrument panel clamp making sure it is not necessary to force mast jacket in place to install clamp. If necessary, adjust dash mounting bracket to fit and tighten.
4. Replace left hand floor pan and steering column grommet. Install steering wheel, horn contact and retaining nut and tighten securely; then install horn button cap and connect horn wire.

Oldsmobile, All Series:

To install steering gear assembly, reverse removal procedure. *NOTE*—Tighten upper mast jacket clamp before tightening steering gear-to-frame bolts.

Pontiac, 1955:

To install steering gear assembly, reverse removal procedure.

MAST JACKET UPPER BEARING REPLACEMENT (Chevrolet Trucks 1947-55)

1. Remove steering wheel. Disconnect horn wire at connector and remove cover plate from mast jacket. Attach a piece of wire to the end of horn wire which enters mast jacket.
2. Screw bearing puller Tool J-2565 into top bearing. Tightening the center screw in puller removes bearing from mast jacket.
3. Transfer tie wire to end of wire attached to new bearing assembly. Start bearing assembly into mast jacket and drive it into place with special driver Tool J-2565. Pull wire through mast jacket and install cover.
4. Install steering shaft upper bearing spring seat (with flared end up) and spring. Install steering wheel, horn assembly and steering wheel retainer lockwasher and nut. Tighten securely.

SAGINAW (CHEVROLET TYPE) 1948 & EARLIER

WORM-AND-ROLLER TYPE

Pass. Cars & Sedan Del. All Models (1939-48)

►CHANGES, CAUTIONS, CORRECTIONS

►**Rubber-cushioned Steering Gear Arm Note:** Will affect steering stability (increased looseness) if bushings become oil-soaked. See Steering Linkage section (below) for bushing renewal instructions.

►**Tie-Rod Packing Fitting Note:** Packing must be correctly fitted when tie rod ball ends installed to insure good seal and prevent entrance of dirt which will cause excessive wear. When installing tie rod ends, place ball stud end of tie rod in steering arm with a hand push fit (omit packing), mark ball stud flush with bottom of steering arm. Remove ball stud, measure from mark to top of dust cover, select correct packing in accordance with this distance (see table) install packing, re-install ball stud.

Tie Rod Ball Stud Packing

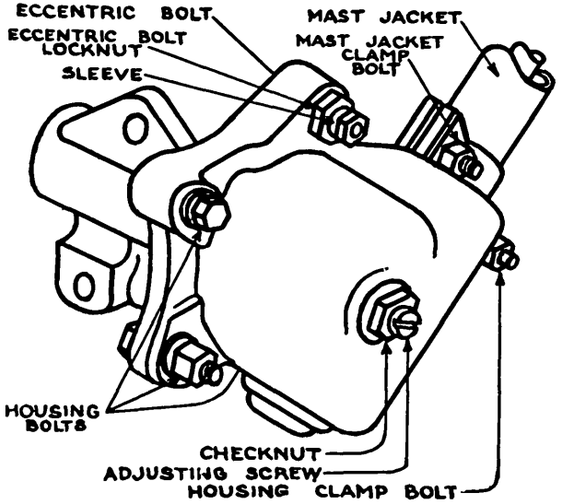
Ball Stud Measurement①	Packing No.	Thickness
3/32-1/8"	3658604	1/8"
1/8-3/16"	599247	3/16"
3/16-1/4"	599836	1/4"

①—If measurement less than 3/32" or more than 1/4", replace worn or damaged knuckle arm, pitman arm, tie rod or tie rod end.

►**Horn Blowing Cap Change (Late '46-47 Stylemaster Cars & Trucks & Replacement on 1941-42 Models).** New type horn blowing cap assembly used which has plate to lock cap securely in place. Removal and installation of cap will be made easier by using Brake Main Cylinder Inspection Cover No. 592865 as a tool.

DESCRIPTION: Roller sector type with an hour glass worm. The sector roller rotates on a double row of ball bearings.

ADJUSTMENT



ADJUSTMENT: Jack up front wheels, remove drag link and steering pitman arm before making any adjustments to steering gear.

Worm Shaft Endplay (1939-48): Adjusting nut on steering gear housing is provided with hexagonal head so that adjustment simplified and should be made as follows: Loosen mast jacket clamp bolt (on lower end of jacket above housing, loosen housing clamp bolt (to free adjuster), use 1 9/16" wrench to turn adjuster at upper end of housing clockwise until all endplay removed and steering gear turns freely, tighten housing clamp bolt and mast jacket clamp bolt (not necessary to loosen instrument panel bracket clamp, do not turn mast jacket clamp when making adjustment as was required on previous models. Check adjustment by noting pull required to turn wheel (use spring scale attached to wheel rim). Pull should be ½ lb. Recheck adjustment if incorrect.

CAUTION—Some backlash must exist between worm and roller when making above adjustment.

Roll r Shaft Endplay:—Loosen locknut on engine side of steering gear housing, turn adjusting screw in until endplay has just been removed (or turn screw in until tight, back screw off until it is free, finally turn screw in until it just contacts end of roller shaft), hold adjusting screw from turning and tighten locknut.

Worm and Roller Backlash:—Turn steering wheel to center r straight ahead position (turn wheel back one half total number of turns from either end position). Loosen three housing-to-bracket bolts,

SAGINAW (CHEVROLET PASS. CAR) TYPE

check backlash or play at pitman arm, loosen eccentric bolt locknut one half turn, turn eccentric bolt and eccentric sleeve equally in opposite directions until all backlash removed (approximately ⅛ turn should be sufficient). Tighten eccentric bolt locknut and housing bolts, check adjustment by noting pull at wheel rim required to turn wheel through center position. Should be 1⅜ lbs. measured at rim of wheel. With correct adjustment, wheel should turn freely through entire range and should have no backlash at center position. CAUTION—When making this adjustment, use extreme care not to turn eccentric bolt and sleeve more than necessary to take up play, any excess will damage steering gear.

STEERING GEAR REMOVAL & INSTALLATION

1939-48 All Models. Remove horn button or ornamental cap (cars with horn ring) and install steering wheel puller Tool J-1618. Thread puller anchor screws into holes provided in steering wheel hub; turn center screw down against centering adapter and strike puller screw head a light blow with a hammer. Remove nuts from mast jacket to instrument panel "U" bolt. Remove the nut from sector shaft and remove pitman arm using puller Tool J-1025. Remove bolt from mast jacket clamp at steering gear housing end and slide clamp up on mast jacket. Remove steering gear mounting bolts and pull steering gear out at bottom.

REMOVAL & INSTALLATION NOTE—It is not necessary to remove vacuum shift or disturb shift adjustments. Raise front end of car about 6" to allow steering gear assembly to clear when being removed from below. Installation should be made from below

Installation—Reverse the instructions given for removal. Note the following:

Mast Jacket Position—When replacing the steering gear in the chassis, the distance from the horn contact ring at top of mast jacket to the shoulder on steering worm shaft should be 1¼". Move mast jacket up or down to secure the measurement, then tighten mast jacket clamp.

Horn Blowing Ring Adjustment—On models with horn blowing ring, adjust contact by loosening horn ring clamp screw at bottom of steering gear hub, and turning the hub housing as necessary until the desired horn ring contact is secured, then tighten clamp screw. Tension of the horn blowing ring may be adjusted by removing the ornamental cap in center of wheel, and turning the two screws as necessary.

STEERING GEAR OVERHAUL

Disassembly: Remove steering gear housing cover bolts and take out sector shaft and roller assembly. Remove wormshaft adjusting sleeve clamp bolt, then pry slot in housing apart with a screw driver and remove adjusting sleeve. Remove wormshaft. Remove wormshaft roller bearings from shaft and steering gear housing.

Sector Shaft Bushings—Remove sector shaft bushings by pressing them out of housing using Sector Shaft Bushing Driver Tool J-762. To install bushings in housing, press one bushing in each end of housing using Bushing Driver Tool J-762. Open end of oil groove in bushing should be toward inside of housing where oil pocket is formed by space between bushings. Ream bushing with special piloted reamer No. 1.125. This piloted reamer reams both bushings in same operation assuring accurate alignment for sector shaft.

Reassembly: Dip lower wormshaft roller bearing in lubricant and install in gear housing. Install wormshaft assembly in housing and then dip upper bearing in lubricant and thread it over wormshaft. Install the adjuster over wormshaft and screw it into housing until all wormshaft end-play is removed. ***(NOTE—Roll wormshaft back and forth while adjusting bearing to make sure roller races are in alignment).*** Install sector shaft and roller assembly in housing. Lubricate sector shaft bushings and install gasket and steering gear housing cover. *(CAUTION*—Make sure sector shaft adjusting screw is backed out and that housing cover is installed in such a way that there is clearance between worm and sector roller). Install housing cover bolts, eccentric bolt and eccentric sleeve in housing. See Adjustment (above).

STEERING LINKAGE

Master Deluxe 1939-41, Special Deluxe 1940-41, All Cars beginning 1942. Cars have individual tie rods between special rubber-cushioned steering gear pitman arm and each wheel. Long right hand tie rod is non-adjustable and toe-in adjustments should be made by turning short left hand tie rod which will insure steering gear roller being on high point of worm with wheels in straight ahead position. NOTE—Make certain that both tie rod ends square on ball studs when clamp bolts tightened.

Rubber-cushioned Pitman Arm Servicing—Replace rubber bushings if oil-soaked. To dismantle assembly, clamp Pitman arm plate (steering arm) in vise, remove cotter pins, nuts, lockwashers from each stud, remove retainer plate, Pitman arm, and bushings. Install new bushing on each stud (metal insert toward plate), install Pitman arm, place additional bushing on each stud (metal insert out toward retainer plate), install retainer plate, lockwashers, and nuts. Tighten nuts evenly to 30-40 ft. lbs. torque, install cotter pins.

1949-54 SAGINAW (CHEVROLET) PASS. CARS

Chevrolet Pass. Car Models (1949-54)

►*1949-52 ROAD SHOCK CORRECTION (Rotation of Steering Wheel):* To correct, install a 3/16" washer between crossmember and upper leg of third arm bracket. Installation of this washer will lower position of third arm ball slightly making it necessary to recheck toe-in and correct as necessary. Also, steering wheel cross bar will be positioned off horizontal requiring the readjustment of the steering connecting rod to maintain steering high spot with wheels in straight-ahead position.

DESCRIPTION: Hour-glass worm and roller sector type with worm gear on steering column shaft meshing with double-tooth roller on cross-shaft (sector shaft).

ADJUSTMENT

ADJUSTMENTS: *NOTE*—Before disconnecting steering connecting rod from pitman arm, take care to note relative positions of steering connecting rod parts before disturbing them. Then proceed as follows:

Worm Shaft Endplay: Remove sheet metal splash guard covering steering gear housing, disconnect connecting rod from pitman arm (CAUTION—note relative positions of connecting rod end parts to insure correct reassembly). Loosen adjusting screw locknut on housing cover, back off lash adjuster screw several turns to provide clearance between worm and roller. Turn steering wheel to within one turn of either end position (turn wheel as far as possible, then turn wheel in opposite direction about one turn). Use spring scale (J-544-A Checking Scale) hooked to wheel spoke at rim to measure pull required to keep wheel in motion.

Bearing Pre-load—⅜-⅝ lb. turning pull (above).

Adjustment—Loosen large adjusting cup locknut on lower end of steering gear housing, turn adjusting cup in until worm shaft has no perceptible endplay. Check pull required to turn wheel (above), tighten locknut when turning pull of ⅜-⅝ lb. is secured.

CAUTION—Recheck pull after locknut tightened.

Worm & Roller Mesh (Backlash): Place steering wheel in exact center of travel with roller on minimum-lash point of worm (count number of turns of wheel from one end position to the other, then turn wheel back ½ this number of turns, remove horn button and make certain that mark on end of shaft points upward, mark steering wheel for reference while making adjustments). Turn lash adjuster screw on housing cover clockwise until all lash removed from worm and roller (NOTE—this screw was loosened in making worm shaft endplay adjustment above), then tighten adjuster screw locknut to 10-15 ft. lbs. Check adjustment by turning wheel one half turn off center "high" spot, attach spring scale at wheel rim and note pull required to turn wheel through the center position.

Backlash Setting—⅞-1⅞ lbs. pull to turn steering wheel through center position (measured as above).

Adjustment—With steering wheel turned one-half turn off center "high" position, loosen lash adjuster screw locknut, turn lash adjuster screw on housing cover clockwise to decrease backlash (and increase required pull), or counter-clockwise to increase backlash (and decrease required pull), tighten locknut, connect steering connecting rod.

CAUTION—Final steering gear setting must be within ⅞-1⅞ lbs. pull (measured as above).

Horn Button Removal: On models equipped with horn button, pry off horn button or ornamental cap.

Horn Ring Removal: On models equipped with horn ring, remove screws holding pivot ring, then remove pivot ring, lock ring and horn blowing spring washer.

Steering Wheel Removal: Remove steering wheel nut and washer. Using steering wheel puller J-2927, thread puller anchor screws into threaded holes provided in steering wheel hub.

Steering Wheel Installation: With steering gear on high point, install steering wheel, with spokes horizontal. Install washer and nut, torque tighten to 25-30 ft. lbs.

STEERING GEAR REMOVAL

REMOVAL OF STEERING GEAR: Remove horn button or cap in center of steering wheel, remove wheel retainer nut and washer from upper end of shaft. If car equipped with horn blowing ring, take out screws holding pivot ring, remove pivot ring, lock ring, and horn blowing spring washer. Use Puller J-2927 (has anchor screws which thread into holes in wheel hub) to remove steering wheel. Remove upper control shaft clamp bolt from shaft connector, remove toeboard grommet and seal. Remove instrument panel mast jacket clamp by taking out nuts and lockwashers. Remove two clutch-head screws attaching gearshift control upper support to mast jacket, pull upper control shaft and support up to disengage shaft connector and remove these parts. Remove clamp bolt nuts and clamp retaining shifter housing on mast jacket, rotate shifter housing assembly away from mast jacket. Remove sheet metal splash guard over steering gear housing, remove steering gear mounting bolts. Remove air duct by taking out sheet metal screws attaching duct to left fender skirt. Rotate steering gear to clear fender skirt, then raise assembly up and forward and remove it from engine compartment.

►**Installation Note**—Reverse removal directions given above and note following points:

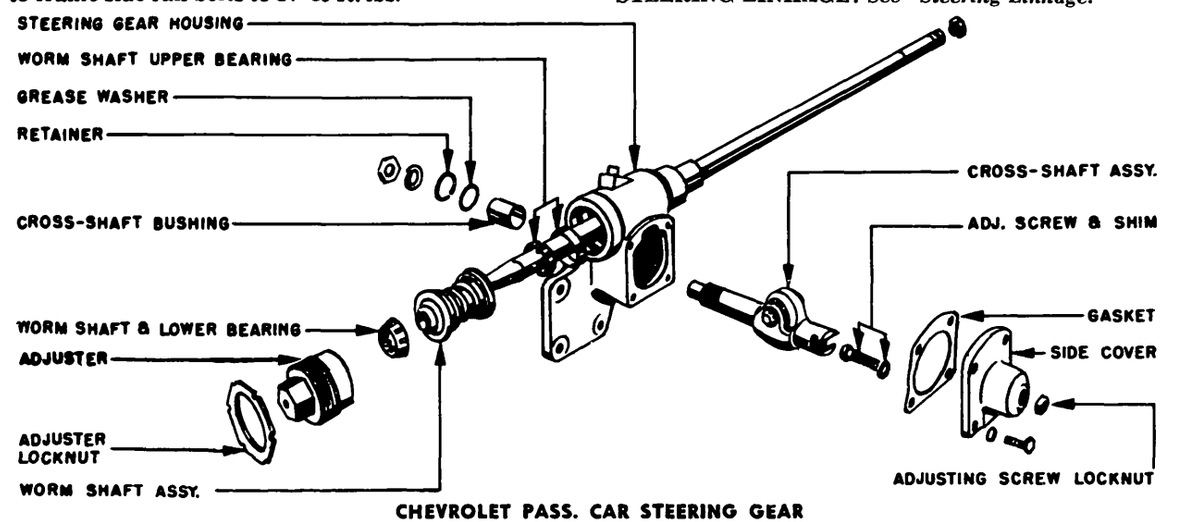
Steering Gear Mounting Bolts—Tighten housing to frame side rail bolts to 27-40 ft. lbs.

Steering Wheel Position—Turn shaft to center "high" point with mark on end of shaft upward, install steering wheel with spokes horizontal, tighten retainer nut on shaft to 25-30 ft. lbs.

STEERING GEAR OVERHAUL

Disassembly: Remove nut and lockwasher on end of sector shaft, use Puller J-1025 to remove pitman arm. Loosen lash adjuster screw locknut and turn adjuster screw several turns counter-clockwise, loosen worm bearing adjuster cup locknut and turn adjuster cup several turns counter-clockwise to remove load from bearings. Take out housing side cover attaching bolts, remove cover as an assembly with the sector shaft and roller (NOTE—If roller does not clear opening in housing, turn worm shaft by hand until roller lines up with notch). Remove worm bearing adjuster cup, withdraw lower bearing, pull worm and shaft out through lower end of housing (CAUTION—protect worm from damage). Remove locknut from lash adjuster screw, remove screw from side cover, slide screw out of slot in end of sector shaft.

Inspection & Repair: Wash all parts in cleaning solvent. Inspect roller bearings, bearing cups, worm, and roller for cracks, pits, roughness and wear.



Sector Shaft Bushing & Packing Replacement—To replace bushing, press bushing, packing, and retainer out of housing in an arbor press using J-1614 driver. Press new bushing in place using same driver. Soak new packing in engine oil, install packing in retainer, press assembly into housing.

Wormshaft Bearing Cup Replacement—Use Mainshaft Bearing Cup Remover J-3183 to pull cup from steering gear housing and from worm bearing adjuster cup. Install new bearing cups with Bearing Cup Replacer J-3182 (install cup on tool and drive into place using great care not to crack cups).

Lash Adjuster Screw Clearance Adjustment—With screw and shim assembled in slot in end of sector shaft, check end clearance of screw in slot with a feeler gauge. If clearance greater than .002", adjust by installing shim of correct thickness.

Reassembly: Reverse disassembly directions given above.

STEERING LINKAGE: *See "Steering Linkage."*

CHEVROLET PASS. CAR STEERING GEAR

SAGINAW (STUDEBAKER) WORM & ROLLER

Studebaker, All Models (1952-55)

►*1953 STEERING REACH ROD LUBRICATION FITTING CHANGE (COMMANDER 4H, C, & K MODELS ONLY):* To make lubrication easier, a 90° fitting has replaced the straight fitting used on the steering reach rod of early production Commander 5-passenger coupe and hard-top. Should interference between the 90° fitting and frame side rail flange occur, install a straight fitting in place of the interfering 90° fitting.

DESCRIPTION: Hour-glass worm and roller sector type with worm gear on steering column shaft meshing with double-tooth roller on cross-shaft.

ADJUSTMENT: Two adjustments required (complete procedure must be followed). Proceed as follows:

Worm Shaft Endplay: Disconnect steering reach rod from pitman arm, loosen steering post jacket bracket-to-instrument panel bolts. Loosen lock nut and turn adjusting screw a few turns counterclockwise to remove load from worm shaft bearings. Turn steering wheel **gently** in one direction until stopped by gear, then back away one turn. Attach spring scale to rim of steering wheel, measure pull required to turn wheel. Pull tangent to rim of wheel should be 6-10 ozs. To adjust shaft bearing, loosen lock nut, turn bearing adjuster clockwise to increase drag and counterclockwise to decrease it. Tighten lock nut, recheck adjustment. Then tighten jacket bracket-to-instrument panel bolts, recheck adjustment to be sure bind was not imposed.

Worm & Roller Mesh (Backlash): Turn steering wheel **gently** through entire range of travel, carefully counting number of turns. Turn wheel back exactly half way to center position. Turn adjusting screw clockwise to take all lash in gear teeth, tighten locknut. Check pull at wheel with spring scale. Pull tangent to rim of wheel should be 14-30 ozs. If necessary, readjust screw to get proper pull.

STEERING WHEEL POSITION: Steering wheel center spoke (3 spoke type) should point straight down, or spokes should be horizontal (2 spoke type) with steering gear in straight-ahead position and on center high point.

STEERING WHEEL & HORN RING OR BUTTON REMOVAL:

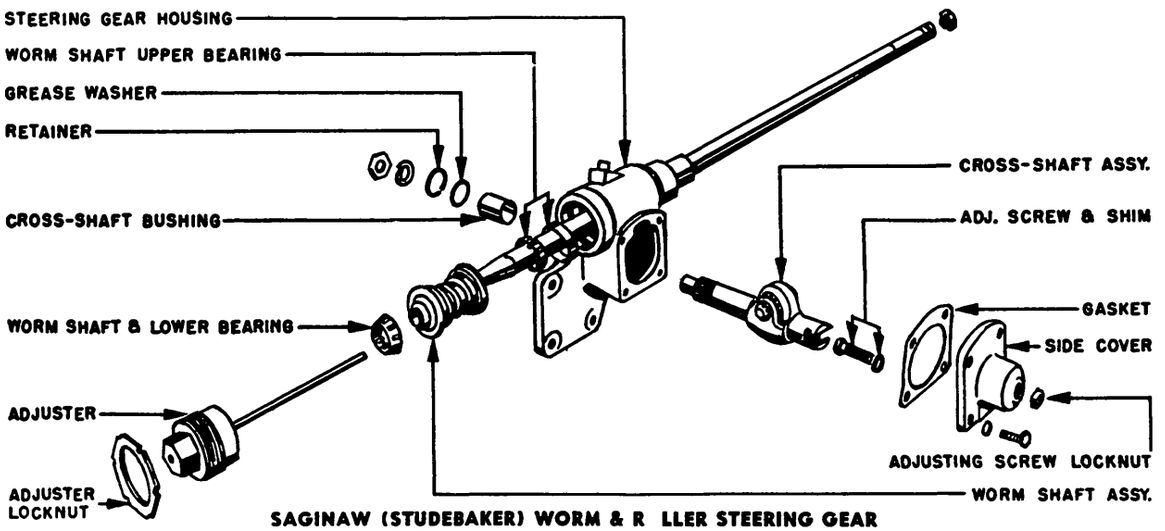
1952-55 Champion (Custom & Deluxe): Removal —Remove horn button or ring by holding steering wheel stationary and turning button or ring 1/3 turn. Remove steering wheel nut, install puller J-5473, remove steering wheel.

1953-55 Champion, Commander (Regal), President Models: Removal—Pry horn button out of wheel, remove three screws in horn ring, remove ring and sponge rubber pad. Remove steering wheel nut. Install adapter in end of steering post, install puller J-5473, remove steering wheel.

Installation (All 1953-55): Align mark on steering wheel hub and mark on end of steering shaft, install wheel. Tighten retaining nut to 23-27 ft. lbs.

STEERING GEAR REMOVAL & INSTALLATION: Removal (1952-54)—Remove horn button assembly and steering wheel. Disconnect and remove battery, disconnect quadrant light cable and starter cut-out switch cables if equipped with Automatic Drive. Disconnect shift lever rod or rods, loosen jacket clamp bolt. Remove jacket bracket retaining bolts from instrument panel, loosen jacket bracket clamp screw and turn bracket to avoid hitting instrument panel when removing jacket. Slip steering jacket off steering post as an assembly into inside of car. Remove front seat cushion. Disconnect reach rod from pitman arm, remove steering gear housing-to-frame bolts. Tip upper end of steering post down, then remove steering gear assembly from engine side of cowl. Wrap cloth around top of housing to prevent spilling of lubricant. Lift housing end of assembly up and remove from chassis.

Installation—To install, reverse removal procedure.



Removal (1955)—Disconnect battery and disconnect horn switch wire at connector. On Commander & President models, also disconnect battery cable at starter switch. On Commander and President Convertible (Hardtop) and Coupe models, remove battery and battery box. Remove steering wheel and steering post jacket assembly. *(NOTE*—Steering gear housing, steering post jacket, and steering wheel can be removed as an assembly. However, on Commander & President Convertible (Hardtop) and Coupe models, it will be necessary to remove left front engine support cushion and raise left front corner of engine approximately 2"). Remove pitman arm using puller J-5664, then remove steering gear housing-to-frame bolts and remove steering gear through hole in dash and into car.

Installation—To install, reverse removal procedure.

OVERHAUL (STEERING GEAR ASSEMBLY): Disassembly—Remove pitman arm retaining nut and lockwasher from cross-shaft. Punch locating marks on pitman arm and end of crossshaft, remove pitman arm. Remove adjusting screw locknut, then turn adjusting screw out one or two turns thereby relieving bushings and bearing of loads. Remove four side cover retaining screws and lockwashers, pull side cover and cross-shaft assembly from housing. If there is interference between housing and cross-shaft roller, turn cross-shaft slightly so that roller wil clear housing. Remove cross-shaft assembly from side cover by screwing adjusting screw through cover. Slide adjusting screw out of slot in end of cross-shaft, remove shim from adjusting screw. Remove worm shaft bearing adjuster assembly and worm shaft lower bearing. Mark directional signal cam and worm shaft for reassembly. Loosen two set screws which hold directional signal cam to upper end of worm shaft, remove cam. Pull worm shaft out of housing, remove worm shaft upper bearing. Pry grease washer retainer out of housing, remove grease washer. With arbor press, press cross-shaft bushing out of housing.

Reassembly: With arbor, press cross-shaft bushing into housing until outer end of bushing is 1/32" below shoulder of housing bore. Install upper bearing cup with hard wood block or lead mallet (avoid tilting in bore), bottom cup against shoulder of bore. Soak new grease washer in engine oil, install it in new retainer, then press retainer and washer into housing until retainer bottoms on shoulder of bore. Place worm shaft upper bearing on worm shaft, slide worm shaft assembly into housing. Upper and lower bearings are interchangeable when new, old bearings should not be interchanged. Install worm shaft lower bearings and bearing adjuster assembly. Adjust bearings so there is no end play. Install bearing adjuster lock nut. Place adjusting screw shim on adjusting screw, slide head of screw into slot in end of cross-shaft. Check clearance between head of screw and bottom of slot. Clearance should not exceed .002". If clearance too great, add next thickest shim (available in sizes .063", .065", .067", .069"). When clearance adjusted, start crossshaft into cover. Insert screwdriver through adjusting screw hole in side cover, screw adjusting screw through side cover as far as cross-shaft will go. Place new gasket on side cover, assemble cross-shaft and side cover to housing. Make sure there is clearance between worm and roller, install and tighten side cover retaining screw and lockwashers. Adjust cross-shaft so there is no clearance between roller and worm when roller on high spot, install adjusting screw locknut. Install pitman arm on cross shaft (marks aligned). Install pitman arm retaining nut and lockwasher, tighten nut to 90-100 ft. lbs. torque. Install directional signal cam on upper end of worm shaft (marks aligned), tighten set screws.

1946-55 BUICK

1946-55, All Series with Synchro-mesh Trans.

▷*NOTE—This control not used with Dynaflow Drive.*

DESCRIPTION: Remote control type with steering column mounted gearshift lever. Design used on these cars has following features:

Gearshift Lever—Lever pivot or bearing formed in housing by fabricated bushing installed in inserted bearing seat and held in place by control housing cap or nut.

Control Shaft—Consists of a tube concentric with steering gear shaft with lower lever welded in place on lower end of tube and control lever housing keyed and clamped on upper end of tube. Tube is mounted on bearing in steering gear housing at lower end and on metal and fabric bearing in direction switch housing at upper end.

Selector Rod—Consists of a square rod within the steering column jacket which is pinned to the selector control lever pivoted on the steering column jacket at the lower end of the rod.

Steering Gear Jacket—Two piece type with flanged slot at point where control shaft lower lever emerges. Upper section has mounting bracket for selector control lever and thrust washer assembly consisting of upper fabric and lower plain steel washer for control shaft end thrust installed in lower end. Lower section has bearing for lower end of shift rod and shedder to exclude dirt.

ADJUSTMENT: Adjust selector control rod and shift rod separately as directed below.

▷*CAUTION*—Inspect all rubber insulations in shift levers and replace if worn. Make certain that selector rod and shaft in transmission moves freely and that return spring has sufficient tension to pull selector control up so that gear shift control lever held down on second speed side.

Selector Rod—Shift transmission to neutral. Disconnect selector rod at selector control lever on steering column, move rod to rear as far as possible, adjust trunnion position on forward end of rod so that trunnion pin engages bushing in selector control lever without disturbing position of lever or gearshift lever, connect rod with fiber washer on each side of insulator, install cotter pin.

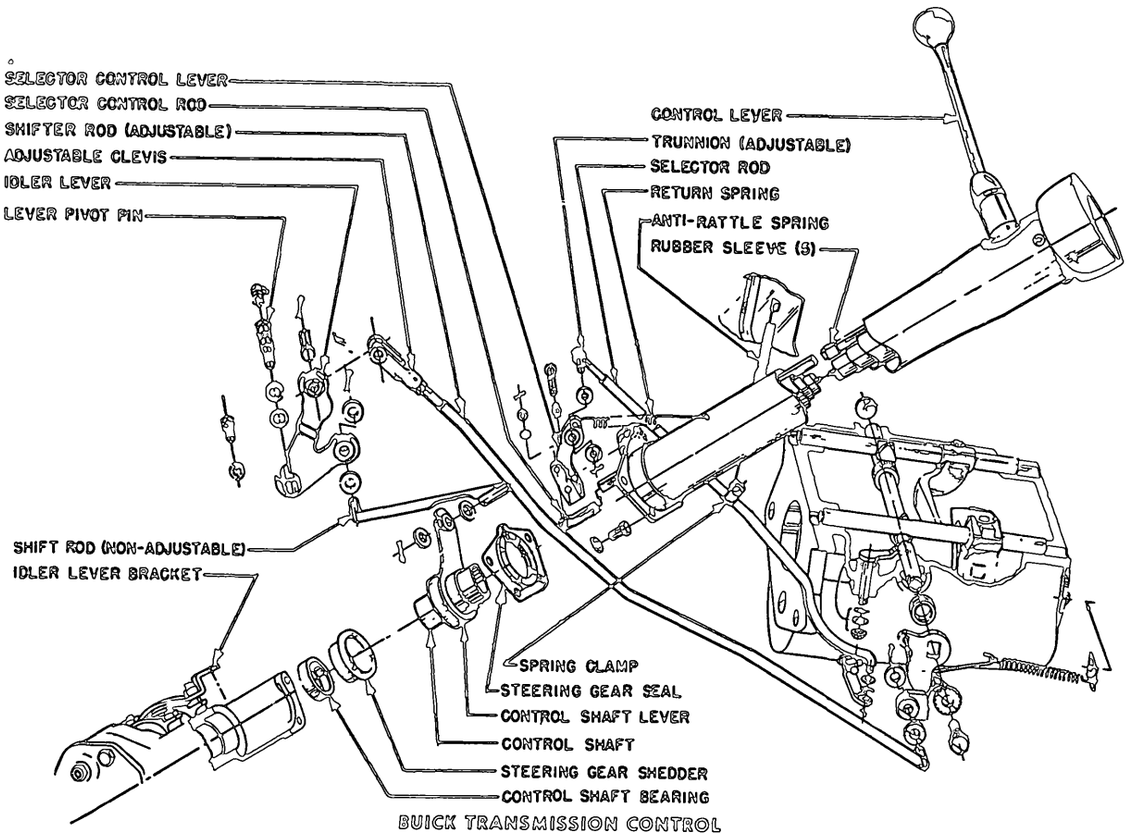
Control Shaft Shift Rod — Shift transmission to Second Gear position, disconnect lower adjustable shifter rod at idler lever on steering column, loosen locknut at adjusting clevis on forward end of rod, pull forward on rod to insure full engagement of transmission gears. Adjust clevis on rod so that clearance between shift control lever and upper edge of opening in steering column jacket is ⅛" with rod connected to lever. Tighten locknut and connect rod. Shift transmission gears to Third Gear position, check clearance between shift control lever housing and lower edge of opening in steering column jacket is likewise ⅛".

▷*CAUTION—This clearance of approximately ⅛" must be maintained between control lever housing and column jacket in each of the gear positions.*

DISASSEMBLY: Gearshift Lever & Bearing. Remove housing nut, withdraw lever, bearing, and bearing seat. When installing lever, see that new bearing installed with large diameter toward lever knob, and that anti-rattle grommet installed in groove on inner end of lever. Coat inner end of lever and socket in selector rod with Lubriplate, see that plunger spring and plunger in place in upper end of selector rod. After lever installed, tighten housing nut securely so that shoulder in nut seats against flange on bearing seat to lock seat in place.

Shifter Rod Idler Lever: Idler lever on steering column is fitted with a bushing and pivots on a bolt on the idler lever bracket. When installing lever, make certain that spring washer and plain washer are in place between lever bushing and head of bolt to prevent rattles. Lubricate idler lever at regular intervals (lubricant fitting on bolt).

REPLACEMENT OF SHIFT CONTROL (Steering Column Units): Gearshift lever and bearing, and control shaft upper bearings can be replaced without removing steering gear. Replacement of selector rod, control shaft, or lower bearings require removal or loosening of steering gear to provide access for column jacket removal.



Control Shaft Upper Bearing: Metal and fabric bearing pressed on upper end of control shaft lever housing in directional switch housing with a flat fabric upper thrust washer, plain steel washer, and spring washer assembled above bearing in that order. To replace bearing, first disconnect all Direction Signal Switch wires at terminals on instrument panel, remove steering wheel (see Steering Gear data), steering shaft upper bearing spring and spring seat. Remove direction signal switch housing from steering column jacket (pull wires up far enough in jacket so that underside of switch housing is accessible for work). Pry out old shift control shaft bearing from bottom of switch housing, withdraw thrust washer, plain washer, and spring washer. Inspect and re-install or replace these parts, then install new control shaft bearing using Replacer J1585 (1949 and before) or piece of heavy wall 1 11/16" O.D. tubing (1950-55) to drive bearing in housing.

▷*CAUTION—Use care not to score bearing (relatively soft fabric type) which will cause hard shifting.*

Control Shaft Lower Bearing: Bushing pressed in upper end of the steering column lower mast jacket with a flanged shedder pressed in the housing above the bearing (shedder fits within cup formed on lower end of control shaft lower lever so that dirt and water excluded from bearing). To replace this bearing with steering gear removed and disassembled (see Steering Gear data), use Remover J1583 to remove old bearing from upper end of steering gear housing, install new bearing with Replacer J1587 (1949 and before) or piece of heavy wall 1⅝" O.D. tubing (1950-53) to drive bearing in housing.

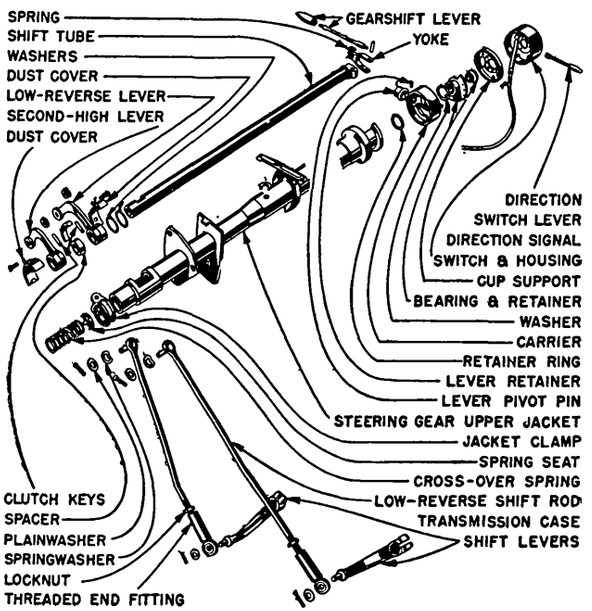
▷*CAUTION—Use care not to score bearing (relatively soft fabric type) which will cause hard shifting.*

TRANSMISSION CASE SHIFTER MECHANISM: *See Buick-Olds-Pontiac Synchro-mesh Transmission.*

BUICK TRANSMISSION CONTROL

1942-48 CADILLAC

All Series (1942-48) With Synchro-mesh Trans.



►**HYDRA-MATIC DRIVE NOTE**—See separate article on Cadillac Hydra-matic Drive for adjustment directions on control lever and linkage used on cars with Hydra-matic Drive. Data below applies to cars with Std. 3 speed transmission only.

DESCRIPTION: Remote control type with steering column mounted gearshift lever. Gearshift lever is pivoted in carrier mounted on upper end of steering jacket and engages shifter tube within steering gear jacket (jacket is notched out for shifter levers on lower end of shifter tube). A single shifter tube is used and normally engages Second-High shifter lever (lower lever) being held in this position by the cross-over spring installed in the jacket at the lower end of the shifter tube. Raising up on gearshift lever causes shifter tube to move down in jacket so as to engage Low-Reverse shifter lever (upper lever). Engagement is by means of shifter keys which engage the levers and tube (keys separated by spacer on tube). Rods connecting shifter levers on steering column and shifter shaft levers on transmission case are adjustable.

ADJUSTMENT: Place gearshift lever in neutral position on Second-High side (normal position). Disconnect Low-Reverse shifter rod at lever on transmission case (rear lever), adjust length of rod so that gearshift lever can be lifted freely into Low-Reverse position with rod connected and without disturbing neutral position of transmission shifter lever and shaft. Adjust Second-High shifter rod (connected to forward lever on transmission case) in same manner. With correct adjustment, cross-over at neutral from Low-Reverse to Second-High positions of gearshift lever should be made freely and without disturbing neutral position of transmission gears and shifter shaft levers.

DISASSEMBLY (1942-47): Loosen clamp holding lower steering column jacket to upper jacket, remove steering gear column and lower jacket as a unit. Remove cross-over spring, seat, and washer from upper end of lower jacket. Remove 4 screws holding Direction Signal Switch and housing in cup support, pull switch, feed wire, and housing off cup, take out 4 Phillips Head screws holding cup and retainer on jacket flange, remove cup. Remove dust shields on lower shifter levers, remove bolts holding cross-over keys in position and slide keys toward outer ends of levers, remove metal dustcover between keys. Slide bearing retainer carrier and shift tube out through upper end of jacket as an assembly. Remove spacer bushing between shifter levers, pull Second-High lever up until lever bushing clears lower edge of slot in jacket, remove lever. Push Low-Reverse lever down until lever bushing clears upper edge of slot in jacket, remove lever. Remove two anti-rattle spring washers from Low-Reverse lever bushings, slide cross-over keys out of slots in both levers. Remove rubber trim pad and insulator from steering column jacket. Remove carrier and bearing retainer from end of shift yoke on upper end of shifter tube, remove retainer ring holding bearing retainer to carrier and remove bearing retainer with bearing and thrust washer.

DISASSEMBLY (1948): Remove steering wheel. Remove upper bearing spring and seat, and cap over end of selector lever at carrier. Drive pin out of carrier boss, remove selector lever. Unscrew and remove direction signal lever. Remove steering column cover panel. Disconnect direction signal switch leads at connectors near steering jacket. Take out four screws, pull switch, wires and housing off cup support (CAUTION—Attach string to wires at lower end housing before pulling wires out, string can be used to pull wires back in). Remove four screws mounting cup support and bearing retainer on jacket flange, remove cup support. Disconnect horn wire at terminal on steering jacket. Remove dust shields over lower shifting levers, and dust cover between levers. Remove bolts holding cross-over keys in levers, slide keys toward outer end of levers. Slide bearing retainer carrier and shift tube out of steering jacket upper end as a unit. Disconnect control rods from shift levers at lower end of steering column, loosen clamp holding lower and upper steering jackets. Raise front end of car and disconnect rod at pitman arm. Take out steering gear mounting bolts. Lower steering gear housing and shaft out of car. Remove spacer bushing between shift levers. Pull Second-and-High lever up until lever bushing clears slot in jacket, remove lever. Push Low-and-Reverse lever down until lever bushing clears slot in jacket, remove lever, remove two anti-rattle spring washers from lever bushings. Remove carrier and bearing retainer from end of shift yoke on upper end of shift tube. Remove retaining ring holding bearing retainer to carrier and remove retainer with bearing and thrustwasher.

CADILLAC 1942-48 TRANSMISSION CONTROL

REASSEMBLY (ALL CARS): Reverse disassembly directions (above) and note the following points when assembling shifter mechanism:

Shift Lever Cross-over Keys—Install keys with tapered ends toward jacket end of levers and with small ends of tapers toward bottom of lever slots.

Low-Reverse Lever Anti-rattle Springs—Install both washers so that they are nested together with concave side up toward upper end of jacket.

Shifter Lever Endplay—After installing shift levers and spacer bushing, check for endplay in levers and remove excessive play by installing shims.

Steering Jacket (1942-47): When installing upper jacket and steering mechanism, see that upper jacket laps over lower jacket approximately 1½", tighten clamp snug but not tight.

Steering Wheel Clearance (1948): When installing steering wheel and horn ring, see that clearance between top of housing and face of wheel hub is 1/16-3/32" (standard wheel). Clearance between top of housing and bottom of horn ring should be 1/32" (Special wheel), when horn ring is depressed so that it strikes steering wheel spoke.

Shifter Rod Connection—Rods should be installed on top of lever with two anti-rattle washers nested together with convex side up (install washers on bottom side of lever).

TROUBLE SHOOTING: If transmission gear engagement not satisfactory, check as follows:

Hard Shifting Complaints:

(1) Check and adjust shift linkage.

(2) Check clutch pedal free play adjustment (set for minimum free travel of 7/8" if clutch dragging). If clutch still drags, check for warped driven member and binding of driven member on shaft.

(3) Check transmission for damaged or tight gears, worn synchronizing drums, broken synchronizer detent springs.

Slipping out of Gear Complaints:

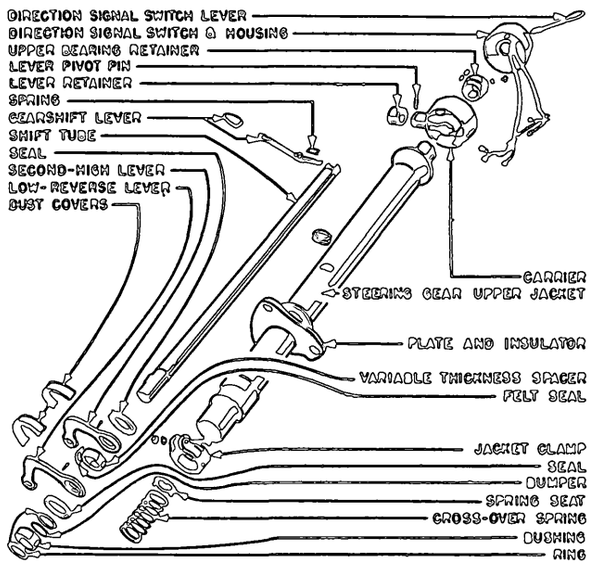
(1) Check and adjust shift linkage. See that control rod rubber bushings not binding (bronze-lined rubber bushings at outer ends of shift levers must not bind on levers—disassemble levers, free bushings, lubricate thoroughly with Lubriplate).

(2) Check Second-speed gear for looseness on shaft or wear in gear or clutch sleeve (slipping out of Second Gear).

(3) Check for misalignment of transmission mounting screw holes, warped or misaligned flywheel housing or transmission case, shim mounting if matching faces run-out more than .003" (slipping out of High Gear).

1949-53 CADILLAC

ALL SERIES (1949-53) with Synchro-mesh Trans.



▷HYDRA-MATIC DRIVE NOTE—Data below applies only to cars with 3-speed synchro-mesh transmission. *See Cadillac Hydra-Matic Drive Transmission for Hydra-Matic Drive control linkage adjustment.*

DESCRIPTION: Remote control type with steering column mounted gearshift lever. Design changed from type used on previous models and new shifter tube and new shift levers are used. Shifter tube has single engaging key which engages keyway in Second-High (upper) or Low-reverse (lower) shift lever. Tube is normally held in upper Second-High position by cross-over spring at lower end and is moved down to engage Low-reverse lever by lifting up on gearshift lever (key disengages from one lever in picking up the other lever).

▷*CAUTION—Shifter levers on steering column are reversed from position on previous car models (Second-High UPPER lever, Low-Reverse LOWER lever).*

ADJUSTMENT: With gearshift lever in Neutral, lift lever up to mid-point of cross-over travel and wedge lever in this position by inserting screw-driver blade between shift lever and pivot pin retainer. Disconnect both shift rods at levers on side of transmission case, see that transmission levers are in neutral position (can be determined by feel of detent engagement). Adjust threaded ends on both shift rods so that rods can be connected without disturbing lever positions, connect rods. Remove wedge from gearshift lever and check lever "feel" at neutral cross-over. If any interference is felt in cross-over position, re-adjust Low-reverse rod slightly (approximately ½-2 turns) until clean cross-over is secured.

DISASSEMBLY: Remove steering wheel (see Steering Gear data), remove upper bearing spring and seat. Unscrew and remove gearshift lever retainer cap, place lever in neutral position, drive pin out of lever boss on carrier, withdraw gearshift lever. Unscrew and remove direction switch lever, disconnect direction signal feed wires at connectors near steering column, attach fishing wire to these feed wires (pull fishing wire into column as feed wires pulled out and leave this wire in column for use in re-installing feed wires). Take out four screws retaining direction signal switch and housing on upper bearing retainer, pull switch feed wires and housing off. Take out three capscrews retaining carrier assembly on jacket, remove carrier, remove bearing and retainer by rotating them counter-clockwise. Remove cotter pins and dustcovers from lower shifter levers on steering column, remove felt dust seal, slide shifter tube up and out of upper steering column jacket. Disconnect shifter levers from control rods, loosen clamp holding upper and lower steering column jackets. Raise front end of car, disconnect steering rod at pitman arm, take out steering gear-to-frame bolts. Lower the steering gear housing and shaft (with cross-over spring and seat) out of steering column. Lift low-reverse lever out of jacket, remove fiber spacer from between levers, turn second-high lever for clearance and remove from slot in jacket. Remove felt washer from recess above and below shift lever opening in jacket. Inspect lower bushing, bumpers, and washers for wear and remove and replace if necessary.

1949-53 CADILLAC TRANSMISSION CONTROL

REASSEMBLY: Install all parts in reverse order of disassembly as given above and note the following precautions and adjustments:

Sealing Ring & Shifter Lever Lubrication—Saturate rings with engine oil and lubricate levers with Lubriplate before installation

Fiber Spacer Installation—Lubricate spacer before installation, see that notch in spacer in line with back edge of levers (to align slot in spacer with slots in levers to permit key on shift tube to be entered when tube installed) and make certain notched face of spacer is toward low-reverse lever.

Endplay Adjustment (Lower End Assy.)—After fiber spacer installed (above), check endplay of lower end assembly. If greater than .005", select and install thicker spacer No. 1455215—.585", 1455216—.591", 1455217—.597", 1455218—.603".

Upper Bearing Retainer—Lubricate retainer threads with Lubriplate, screw retainer into carrier until top face of retainer is 21/32" above shoulder on rim of carrier, install carrier over shift tube so that shoulder on retainer seated against upper end of outer jacket, tighten retainer screws to 7-9 ft. lbs.

Gearshift Lever Bumper Screw Installation & Adjustment—With gearshift lever installed and ball end of lever engaged in hole in upper end of shift tube, depress lever until shift tube key clears low-reverse lever, rotate lever so that keyway is out of line with key, pull up on gearshift lever until key contacts face of low-reverse lever. Install rubber bumper in bumper screw (bumper must be completely seated in screw), turn screw in until bumper just contacts pad on lever (check by shaking outer end of lever and tightening screw until all longitudinal play eliminated), then back off screw ½-turn and lock screw by staking carrier metal into screw slot.

Steering Wheel Clearance—Clearance between top of housing and face of standard steering wheel hub should be 1/16-3/32". On special steering wheel, clearance between top of housing and bottom of horn ring should be 3/16" with horn ring depressed so that it strikes steering wheel spoke.

1940-48 CHEVROLET

All Pass. Cars & Sedan Del. (1940 to 1948)

▷CHANGES, CAUTIONS, CORRECTIONS

▷Gearshift Lever Rattle Correction: Caused by play at swivel in upper support and should be correct as follows: Install special Gearshift Control Anti-rattle Spring, #606418, by snapping spring over gearshift control shaft and steering mast jacket at point immediately below instrument panel mast jacket clamp. This 'S' shaped spring will correct rattle without causing drag on control shaft.

▷Gearshift Lever Flutter (Idle or High Speed) Correction—May cause jumping out of High Gear at high speed. To correct, install Vacuum Cyl. Valve Friction Spring, No. 3655072, as follows: Slip forward end of rubber boot off rear end of metal boot over reactionary levers, take out two bolts fastening halves of metal boot together and remove top half. Remove piston rod yoke clevis pin and disconnect piston rod yoke and valve link from reactionary levers. Pull out vacuum cylinder valve rod, snap friction spring in place on rod about midway between valve and valve rod guide with spring 'prongs' pointing out toward clevis pin yoke, reassemble rods and boot.

▷Cabriolet Cars (1941-42) Vacuum Cylinder Tubing. An "S" shaped piece of tubing was used to connect vacuum lines near the X-member to prevent interference and damage to vacuum line at this point on these models only and rubber hoses must be cemented to this tube (no cement used on first 1941 cars). When installing units, use sufficient cement (Chevrolet #378727—Meiflex or U. S. Rubber Cement Type M-5036, #121177—Inter-coastal SMR-2218) to provide good seal at both ends of tube and rotate tube so that no interference exists before cement sets.

CAUTION—Cement tube on all early 1941 cars which were not cemented in production.

DESCRIPTION

DESCRIPTION: Vacuum assistor, with gearshift lever mounted on steering column and vacuum power cylinder mounted on bracket at left side of transmission case. Design changed from type used on 1939 models as follows (new vacuum cylinder mounting used on 1942 and later models only):

Gearshift Lever (Steering Column Unit)—One shaft only is used (in tubular housing on steering column) and operates both selector (cross-shift) rod and gear engagement (vacuum cylinder) rod. Gearshift lever is new type and lifts up on control shaft when lever lifted into Low-Reverse position.

Vacuum Cylinder & Linkage—Reactionary lever assembly now riveted together and covered by metal boot. Mounting changed to provide for new type side-mounted transmission shift mechanism. Vacuum cylinder operates in same manner as 1939 type.

Transmission Case Shifter Mechanism—New type shifter mechanism mounted in side cover on transmission case. See Chevrolet Transmission article for shifter servicing data.

CONTINUED ON NEXT PAGE

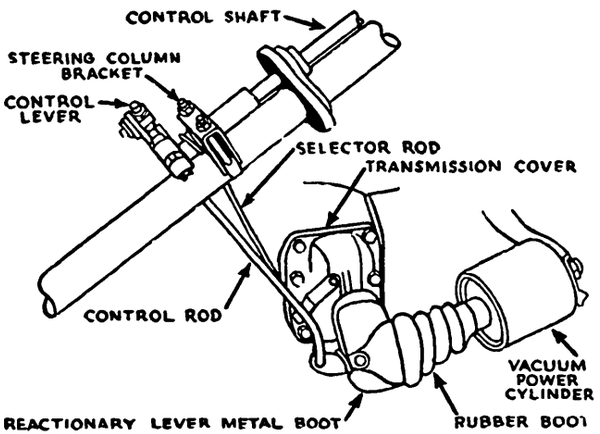
1940-48 CHEVROLET (C nt.)

ADJUSTMENT: If operation unsatisfactory or shift mechanism dismantled for servicing, adjust as follows:

Selector Rod—Loosen check nut on selector rod adjustment (at lower end of steering column), pull selector rod forward as far as possible, adjust swivel on rod by screwing it up or down on rod so that distance between lower side of steering wheel and top of gearshift lever is 1 27/32" with selector rod connected to selector control lever. Install washer and cotter pin on swivel pivot and lock adjustment by tightening selector rod check nut.

Control Rod (Gear Engagement Rod)—Set gearshift lever in horizontal position, loosen checknut on control rod. Push control rod to rear until all clearance has been taken up and note location of swivel with reference to shift control lever, then pull rod forward until all clearance has been taken up and again note swivel location. Neutral valve position is midway these two positions. Hold control rod in this neutral position, adjust swivel position on control rod (screw swivel up or down on rod) until swivel pivot just enters hole in shift control lever. Install flat washer and cotter pin on swivel pivot, lock adjustment by tightening control rod check nut.

STEERING COLUMN UNIT DISASSEMBLY & REASSEMBLY: The gearshift lever can be removed without completely disassembling unit as follows:



Gearshift Lever Removal—Place shift lever in Reverse, depressing pivot pins 3/32" and then lifting up and out on lever. To remove anti-rattle spring and pivot pin spring, compress legs of pivot pin spring and lift up. When reassembling gearshift lever, coat control shaft ball with graphite grease, install anti-rattle spring in control shaft ball and over neck of control shaft, thread pivot pins on ends of spring and in holes in gearshift lever swivel, thread gearshift lever over this assembly, compress pivot pins and press down on top of lever until pivot pins snap into place.

Disassembly—Disconnect gear engagement control rod and selector rod at lower end of steering column by taking out cotter pins and removing flat washers. Remove clamp bolt on shift lever at lower end of control shaft, remove lever and spring. Remove horn button and steering wheel nut, pull steering wheel (use puller J-1618 to protect shaft threads). Remove instrument panel steering column jacket clamp. Take out two screws in upper support on steering column jacket, pull control shaft and upper support up and out of lower support. If gearshift lever to be removed, see preceding paragraph for directions.

Lower Support Bushing Servicing—If bushing worn, press old bushing out, press new bushing in until distance from face of support to lower end of bushing is 19/64".

Reassembly—Screw gearshift lever swivel into upper support until shoulder on swivel extends approximately ⅛" above support. Install control shaft by threading it through upper support and swivel. Install gearshift lever (see above). Install lower support on steering column jacket and see that key engages slot, tighten clamp bolts just snug (excessive tightening will collapse jacket). Screw upper support up or down on swivel until clearance between lower edge of gearshift lever and top of support is 3/32-⅛". Thread toeboard grommet over control shaft, install control shaft through lower support and attach upper support to steering column by installing two screws. Install spring and lever on lower end of control shaft making certain that end of selector operating lever is engaged in slot on control shaft lever, install clamp bolt and tighten securely. With steering wheel removed, check distance from top of horn blowing ring on mast jacket to top of shoulder on steer-gear shaft. Distance should be 1¼" (plus 1/32", minus 0"). If not correct, loosen mast jacket clamp at steering gear housing, move mast jacket up or down as required, tighten clamp. Adjust Control Rod and Selector Rod (see Adjustment above). Check distance from upper face of control shaft lever to lower face of lower support bracket on steering column. If this distance not ¾", adjust by loosening lower support clamp bolts and moving support up or down on steering column.

CAUTION—Do not tighten support clamp bolts excessively which will collapse steering column jacket.

TRANSMISSION LEVER LINKAGE DISASSEMBLY:

Note—Reactionary lever assembly is of riveted construction and cannot be disassembled (service as an assembly).

Disassembly—Disconnect shift control rod from reactionary lever assembly, remove vacuum hose from vacuum inlet stack and slip forward end of rubber boot off rear end of metal boot. Remove two screws holding metal boot halves together, lift off outer half of boot. Take out piston rod yoke clevis pin, push cylinder rod into cylinder to disconnect it from reactionary lever, then re-install clevis pin to prevent valve adjustment being disturbed. Loosen operating lever clamp bolt, pull reactionary lever assembly off operating lever shaft, remove second half of metal boot.

Servicing—Clean reactionary lever assembly with clean gasoline, examine rubber seal at front of metal boot and replace if damaged.

Reassembly—Coat reactionary levers lightly with graphite grease, place inner half of metal boot on operating lever shaft, thread rubber seal over idler lever, install reactionary lever assembly on operating lever shaft to point just beyond chamfered end of shaft and tighten clamp bolt. Pull piston rod forward and connect yoke and valve link to reactionary levers, install piston rod valve clevis pin. Assemble outer half of metal boot and install the two retaining screws. Slip end of rubber boot over rear end of metal boot, install vacuum hose and shift control rod.

VACUUM CYLINDER REMOVAL: Disconnect both the vacuum and air hoses, remove outer half of the metal boot and disconnect piston rod and valve links from reactionary levers (see Servicing Transmission Lever Linkage above for directions). Take off cotter pin and nut on cylinder mounting stud, remove vacuum cylinder.

Installation—Install rubber cushion and steel retainer on mounting stud, insert stud through hole in bracket, install steel retainer, rubber cushion, flat washer and nut on stud, tighten nut just sufficiently to allow cotterpin to be installed (mounting must be flexible). Connect piston rod yoke and valve link to reactionary levers, install vacuum and air hoses.

Vacuum Cylinder Lubrication:—Must be removed from car as directed above (cannot be lubricated on car). Stand the cylinder on the mounting end, pull valve link forward to open valve, pour ½ oz. shock absorber insulating fluid into cylinder through vacuum inlet stack. Push valve rod into cylinder as far as possible, pour additional ½ oz. of fluid into vacuum inlet stack. Allow time for fluid to flow into cylinder, then work piston rod in and out several times and turn rod at same time to spread fluid over cylinder walls and piston leather. NOTE—Cylinder can be washed out by following directions given above using 2 ozs. of fluid and draining fluid by inverting cylinder and moving valve rod until fluid flows out. Repeat until fluid drained from cylinder is clean (cylinder need not be lubricated after this process completed).

Vacuum Cylinder Valve Adjustment:—If vacuum valve adjustment disturbed by dismantling or servicing operations, adjust as follows: Disconnect piston rod and valve link from reactionary levers (see Servicing Transmission Lever Linkage above for directions). Install special adjusting bushing J1452-5 within valve link and re-install clevis pin. Run engine to provide vacuum source. Move valve link out or away from cylinder until all clearance between link and adjusting bushing is toward front of car, piston rod should move out of cylinder slowly in this position. Then move link in toward cylinder until all clearance between link and adjusting bushing toward rear of car, piston rod should move into cylinder in this position. If piston rod moves out but does not move in, valve link should be screwed out on valve rod. If piston rod moves in but does not move out, valve link should be screwed in on valve rod. To adjust, remove clevis pin and change valve link position ½ turn at a time until correct operation is secured.

Valve Friction Spring Installation:—To install spring, remove outer half of reactionary lever boot and disconnect reactionary levers from vacuum cylinder (see Transmission Lever Linkage Disassembly directions above), pull out on valve rod in vacuum cylinder, snap friction spring in place on rod midway between valve and valve rod guide with closed end of spring toward back of cylinder, push valve rod back into place, connect reactionary levers and replace metal boot.

NOTE—This spring necessary to prevent 'flutter' in gearshift lever at idling speed.

Air Clean r Servicing:—At 10000 mile intervals, remove cleaner, wash in gasoline, and dip in engine oil before re-installing.

1949-54 CHEVROLET PASS. CARS & 1947-55 TRUCKS

Pass. Cars (1949-54) Synchro-mesh Trans.
Half-Ton & ¾-Ton Trucks (1947-55)
Forward Control Trucks (1948-55)

▷POWER GLIDE AUTOMATIC TRANSMISSION NOTE—Control linkage is adjusted differently. *See Chevrolet Powerglide Automatic Transmission data for linkage adjustment.*

▷GEARSHIFT CONTROL LEVER RATTLE (Early 1949 Pass. Cars): Rattles in High Gear position, or on deceleration in 50-30 MPH. range, may be corrected as follows:

High Gear Rattle Correction—Check fit of shift lever on threaded swivel. If loose, remove lever and squeeze sides together for snug fit on swivel.

Deceleration Rattle—If lever snug fit on swivel (above) and rattle persists, replace original Part No. 3686805 Control Shaft Spring with new type spring No. 3692295. This spring is installed in gearshift control shaft housing at lower end of steering mast jacket ahead of dash and is hooked over second-and-high control lever to steady control lever in high gear and to counterbalance gearshift lever.

DESCRIPTION: Remote control type with gearshift lever mounted on steering column. Gearshift lever is pivoted in mounting bracket on upper end of steering column and has engaging dog or lug on lower end of control shaft which engages one or the other of the two "inner levers" in the housing at the lower end of the steering column.

Passenger Car Gearshift Control & Shifter Mechanism: Gearshift control is manual type (no vacuum cylinder) of same design as used on truck models. Control levers on lower end of steering column unit are linked directly to shifter levers on transmission case and no idler bell crank used. Shifter mechanism on transmission case is new type with individual shifter levers and shafts for Low-Reverse and Second-High speeds (see illustration).

Forward Control Truck Gearshift Control & Shifter Mechanism: Same design as other trucks (above) except that both control rods have idler bell cranks mounted on flywheel housing.

GEARSHIFT CONTROL ADJUSTMENT: Adjust all models as follows:

▷Dubl-Duti (Forward Control) Adjustment Note—Front floor pan must be removed for access to control rod swivels as follows: Take out pan attaching screws, disconnect wiring to stop light switch, disconnect accelerator pedal rod, remove pan.

1—Clearance between lower edge of steering col. shift lever and top edge of upper support below lever should be 3/32"—1/8". To adjust, remove upper bolt from shaft clamp on steering column (connecting upper and lower control shafts), take out two screws in upper support just below lever, remove shift lever and upper control shaft assembly. Screw upper support up or down for correct 3/32"—1/8" clearance, re-install assembly on steering column.

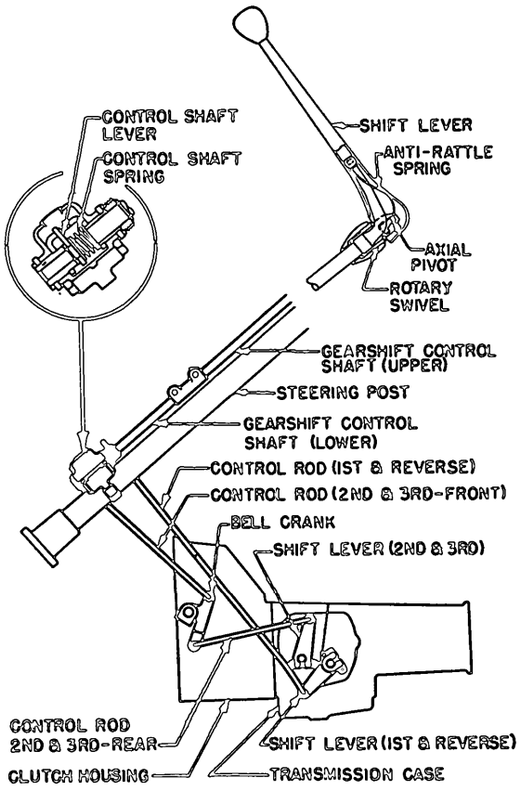
2—Clearance between end of gearshift lever and underside of steering wheel rim is shown in table below. To adjust, loosen two housing assembly clamp bolts at lower end of steering column mast jacket, raise or lower assembly (with control shafts and gearshift lever at upper end) until clearance is correct, tighten clamp bolts.

Gearshift Lever-&-Wheel Clearance

1947-48 Trucks	2 9/16" ± 1/8"
1949-53 Trucks	2 13/16" ± 1/8"
1949-54 Pass. Cars	2¾" ± ¼"
1954-55 Trucks (Exc. ¾-Ton F.C.)	2 13/16" ± 1/8"
1954-55 ¾-Ton Forward Control	2 9/16" ± 1/8"

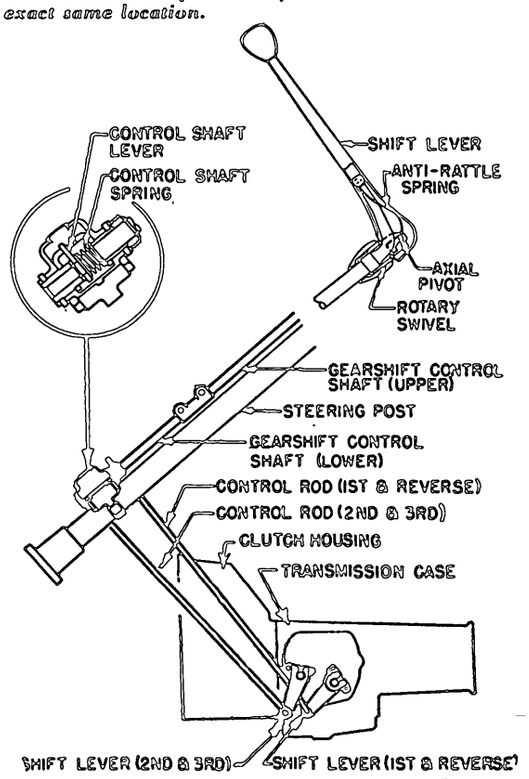
3—Gearshift lever should be horizontal with transmission in neutral. To adjust, disconnect the 2nd & High control rod swivel (1947-48 Trucks), or loosen the swivel clamp (Others) at the housing outer lever (lower lever on steering column). Move this lever as required to set the gearshift lever in a horizontal position, then adjust swivel on end of rod so that gearshift lever position will not be disturbed when rod connected. Connect rod or tighten swivel clamp.

4—Check shifter gate alignment on inner levers in housing on steering column (visible when cover on housing removed). This alignment is necessary to insure smooth cross-over in neutral. To adjust, disconnect the 1st & Reverse control rod swivel (1947-48 Trucks), or loosen the swivel clamp (Others) at the housing outer lever (upper lever on steering column). Move the outer lever as required to align the upper shifter gate with the lower shifter gate in the housing, then adjust swivel on end of rod so that lever position will not be disturbed when rod connected. Connect rod or tighten swivel clamp.



TRANSMISSION SHIFTER DISASSEMBLY: Cover on side of transmission case must be removed as follows: Disconnect shifter rods, drain lubricant, take out shift lever lock bolts, and pull lever off each shifter shaft. Remove cover from transmission. Take out shifter interlock retainer capscrews or nuts and locks on studs, remove retainer. This will permit removal of shifter shafts and fork assemblies, shaft seals, poppets, springs, and interlock.

▷*TRANSMISSION SHIFT LEVER REPLACEMENT CAUTION:* Do not replace transmission shifter levers without removing cover assembly from transmission. When replacing shift levers on shifter fork shafts without removing cover, shifter fork shafts will be forced against gears and it will be impossible or difficult to shift gears due to interference.



DUEL-DUTI (FORWARD CONTROL) CONTROL RODS: Consist of upper rods (from steering column to idler levers on flywheel housing), and lower rods (from idler levers to transmission case levers).

Disassembly of Control Rods: Remove front floor pan (take out attaching screws, disconnect wiring to stop light switch, disconnect accelerator pedal rod, remove pan). Disconnect rods by removing cotter pins, flat washers, and springs at each end (remove upper rods and swivels as an assembly).

▷*CAUTION—Note position of each rod and re-install in exact same location.*

1949-55 ½ & ¾ TON TRUCK TYPE

1949-54 PASSENGER CAR TYPE

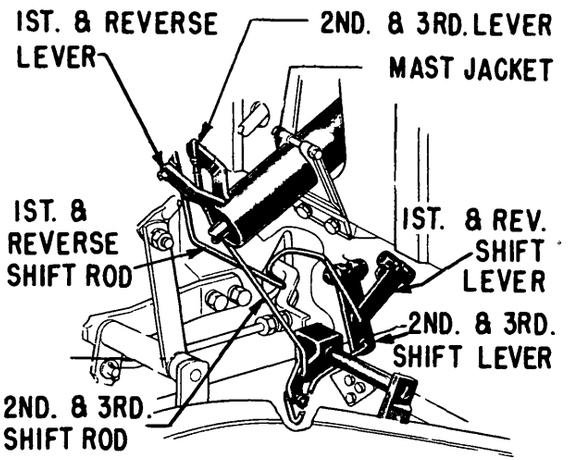
1955 CHEVROLET PASS. CARS

Pass. Cars (1955)

►*1955 HARD SHIFTING CORRECTION.* Install Transmission Control Conversion Kit, Part No 3731061 in mast jacket & shifter shaft assembly, and install new type 1st & Reverse gear, counter gear, and reverse idler gear. *See "1955 Chevrolet Transmission" for installation of these new parts.*

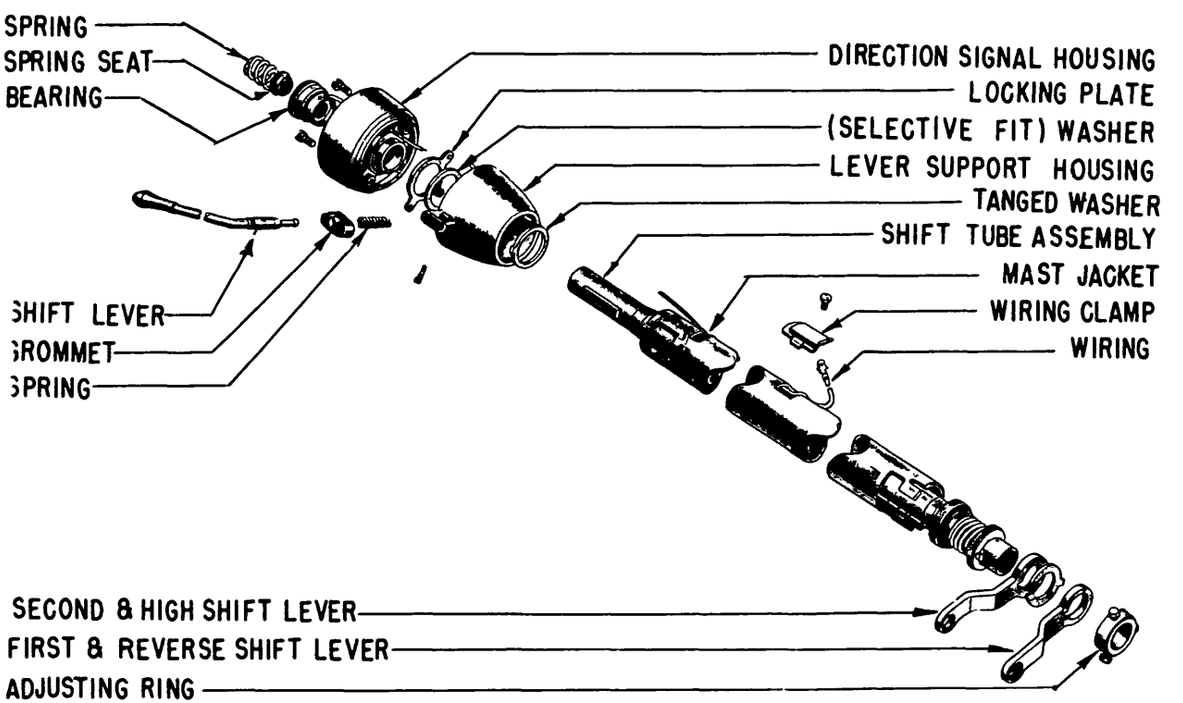
DESCRIPTION: Remote control type with gearshift lever mounted on steering column and connected to a shifter tube within the steering column Shift levers at lower end of steering column are actuated by a shifting key on the shift tube.

GEARSHIFT LEVER ADJUSTMENT: Loosen shifter rod locknuts on transmission shift levers at lower end of steering column Move the shifter rods through swivels until transmission is in neutral and the first & reverse lever (lower lever) is at the midpoint of its travel (center of slot). Align second & third shift lever (upper lever) with the first & reverse lever and tighten swivel fitting locknuts. *CAUTION–Shifter tube levers must be in alignment or key will not enter keyway in levers.*



►*TRANSMISSION SHIFT LEVER REPLACEMENT CAUTION:* Do not replace transmission shift levers without removing cover assembly from transmission. When replacing shift levers on shifter fork shafts without removing cover, shifter fork shafts will be forced against gear and it will be impossible or difficult to shift gears due to interference.

SHIFTER TUBE & MAST JACKET OVERHAUL: (Removal)–Disconnect all electrical connections and remove the back-up light switch (where installed), from mast jacket. Remove two rubber cover upper fasteners from inside of dash panel at mast jacket opening. Pry off horn button or ornamental cap and remove horn mechanism Slide rubber seal away from covers, then remove lower cover retaining screw and washer and remove lower and upper covers. Remove steering wheel nut and washer from end of steering gear shaft and remove steering wheel from column using Wheel Puller J-2927-A. Remove spring and spring seat from end of steering shaft. Remove nut, washers and clamp bolt from dash panel attaching bracket. Disconnect transmission control linkage from shifter levers at swivels. Remove swivels from shifter levers. Remove nuts and washers retaining clamp to bottom of instrument panel and remove clamp and rubber shims. From inside car, pull mast jacket assembly carefully off steering shaft, rotating as necessary to clear dash clamp. Work shift levers through dash seal by stretching the seal to clear levers.



Disassembly: Slide rubber grommet back from lever support housing and drive out shift lever pin. Remove shift lever and anti-rattle spring. Remove single screw and clamp where wire enters mast jacket Remove direction signal housing retaining screws at top of steering column and remove housing (*NOTE*–It will be necessary to shift position of direction signal controls to gain access to the retaining screws). When removing housing be careful not to damage horn and direction signal wiring connections. Remove locking plate and washer. Remove shift lever support housing then remove the tanged washer from mast jacket. Reverse mast jacket and loosen retaining bolts on adjusting ring while holding ring to release compression of spring slowly. Remove adjusting ring. Remove the two shift levers from lower end of steering column. Retain the spacer located between the shift levers. Remove shifter assembly by pulling it out of mast jacket

Reassembly: Reverse the disassembly procedure above, and note the following: Upper shift lever is stamped "U" and lower shift lever is stamped "L" Lubriplate and install shift levers on shifter tube after tube is inserted in mast jacket. Place a .010" feeler gauge between the second & third shift lever and spacer, then apply a force sufficient to push the adjusting ring into mast jacket and up against the feeler While holding in this position, tighten the three adjusting ring bolts. Remove feeler gauge. When direction signal housing installed, check endplay between lever support housing and direction signal housing. If not within specified limits of .004- 009", remove direction signal housing and locking plate and install proper size spacer washer for correct endplay (*NOTE*–Four thicknesses of spacer washers are available. .035", .039", .043", .047").

Installation: Reverse removal procedure above, and note the following: Before tightening mast jacket clamp bolts, install the steering wheel and position mast jacket so there is 1/16" clearance between steering wheel and mast jacket by placing a 1/16" feeler between top edge of direction signal housing and bottom outer edge of steering wheel. Tighten mast jacket clamp bolt. After installation completed, adjust shift levers as indicated above.

TRANSMISSION SHIFT LINKAGE

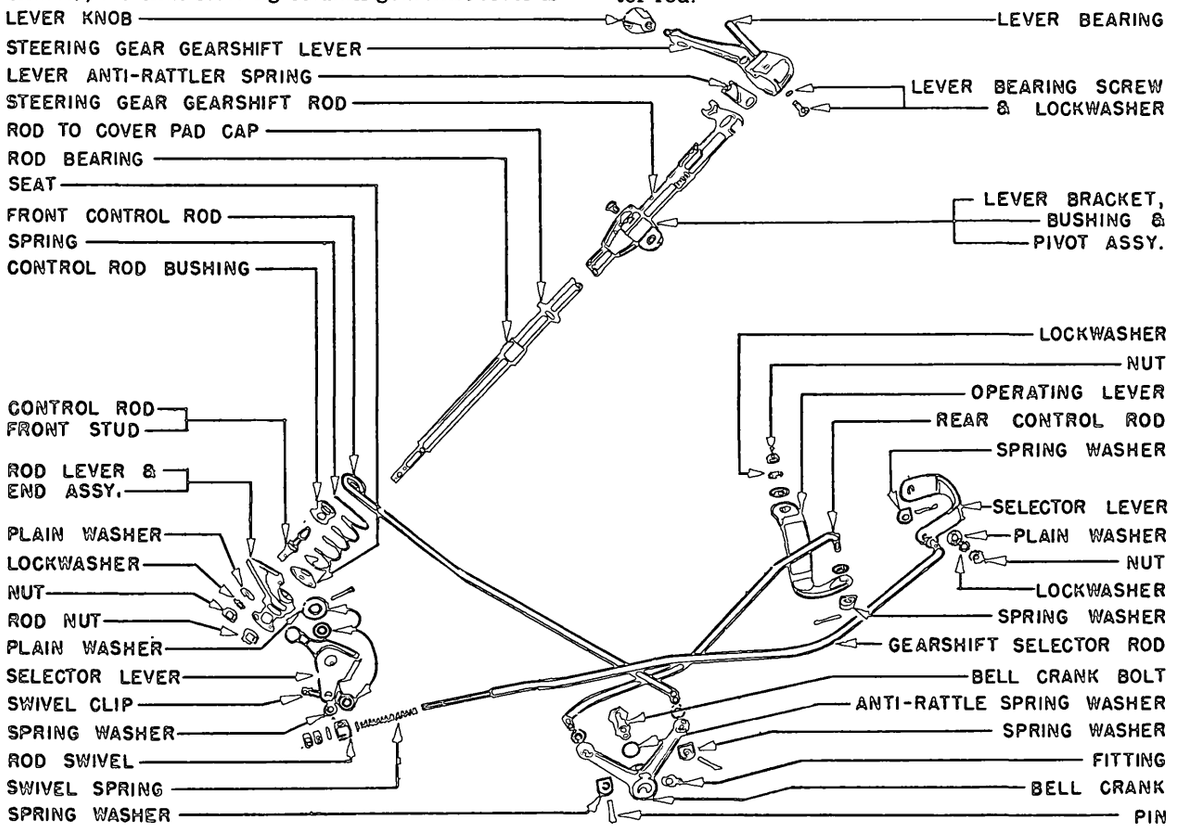
1955 CHEVROLET TRANSMISSION CONTROLS

1946-55 CHRYSLER, DESOTO, DODGE & PLYMOUTH

All Models (1946-55 With Synchro-mesh Trans.)

▷Hydraulically Controlled Transmissions—Special controls are used in conjunction with these optional transmissions. See articles on these transmissions for control data.

▷*1955 PLYMOUTH GEARSHIFT LINKAGE RATTLE CORRECTION:* To correct gearshift lever shake, remove gearshift bellcrank and turn it 180°. Assemble the shift control rod in smaller hole of bellcrank to reduce looseness. Add as many anti-rattle washers on bellcrank stud and on clevis pin (if clevis loose on bellcrank), as possible



DESCRIPTION: Remote control with gearshift lever mounted on steering column.

Transmission Case Shifter Mechanism—Refer to Chrysler Transmission article for complete data.

ADJUSTMENT: Control Rod (Gear Engagement): Loosen nut on control rod connector stud on lever at lower end of steering column control rod, make certain that transmission gears and shift lever are in neutral position (can be determined by feel of detent balls engaging neutral notches in shifter shafts), see that steering column gearshift lever is horizontal, tighten stud nut securely (stud hole in lever is slotted to permit adjustment). *NOTE*—On 1955 Dodge & Plymouth, adjustment is at lower end of control rod.

Selector rod (1946-55 Exc. 1953-55 Chrysler & Dodge)—See that transmission gears are in neutral position. Adjust selector rods as follows: Loosen locknut on forward end of selector rod at trunnion on steering column selector lever, tighten adjusting nut until all play removed from rod and lever, then back nut off one-half turn to provide correct clearance, tighten locknut. *NOTE*—1953-55 Plymouth have adjustment at lower end of rod.

Selector Rod (1953-55 Chrysler & Dodge)—Set shift rod in its normal raised position. Adjust crossover linkage to secure ⅜-⅝" free play movement of gear shift knob when transmission is in high gear position by adjusting selector rod so swivel at rear end of selector rod can be placed freely in selector lever hole (rear lever on transmission), when selector lever is 1/32" back from contact with shift fork. There should be no tension or compression on selector rod.

1946-55 CHRYSLER, DESOTO, DODGE, PLYMOUTH TRANSMISSION CONTROLS

DISASSEMBLY: Remove the horn button, horn wire and steering wheel. Disconnect selector rod and gearshift rod at steering column. Take off nut on lower end of control rod and remove rod end (selector lever collar), lever and spring from lower end of rod. Take out two screws attaching gearshift lever pivot bracket to steering column (except Plymouth). Gearshift lever and control rod can then be withdrawn at upper end of steering column except that on 1941-42 DeSoto & Dodge cars, remove attaching bolts and separate steering column bracket at dash, then withdraw gearshift lever and control rod as an assembly. On Plymouth models, remove gearshift lever (see below), then withdraw control rod at upper end without disturbing lever pivot bracket. Install control rod in same manner and adjust rods as directed above.

Gearshift Lever Removal—To remove lever from control rod, remove shift lever bearing and screw from lever and pivot bracket. Press down on end of lever so that end clears control rod, then pull lever out to disengage lever pin from fork on rod. Install lever in same manner.

Idler Lever Lubrication—Idler lever on bracket on left hand side of clutch housing has regular lubrication fitting and should be lubricated at 6000 mile intervals with semi-fluid chassis lubricant to prevent lever sticking which will cause hard shifting.

REASSEMBLY: Reverse the disassembly procedure as given above.

1940-48 FORD, LINCOLN, MERCURY

All Pass. Car Models (1940-48)

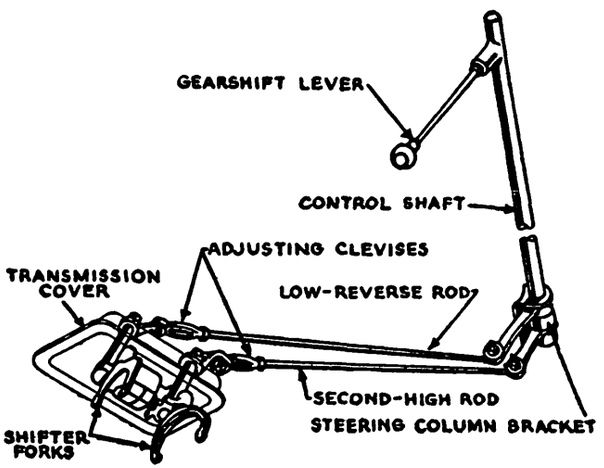
DESCRIPTION: Remote control with steering column mounted gearshift.

ADJUSTMENT: Adjustment should be checked whenever steering column position is changed or when linkage disconnected. Before making adjustments, make certain that both shift levers on transmission case are in neutral with detent balls engaging neutral notch in shifter shaft sectors (can be determined by feel with control rods disconnected). Disconnect Low-Reverse control rod at adjustment end (see Note), loosen locknut and adjust clevis on end of rod so that gearshift lever moves up and down freely (cross-shift at neutral) with control rod connected. Second-High control rod will not ordinarily require adjustment. Make certain that gearshift lever has full travel in both directions so that gears are fully engaged (detent balls should engage end notches in shifter shaft sectors with gears engaged).

DISASSEMBLY (Steering Column Unit): This entire unit is mounted on steering column by retainer clamped in bracket bolted on column and can be dismantled after bracket has been loosened and retainer setscrew removed. Gearshift lever is pivoted on pin in control tube elbow and inner end engages fulcrum pin within upper end of control tube. If assembly dismantled, make certain that spring installed at lower end of fulcrum pin and that bushing and boot installed on upper end of fulcrum pin when it is reassembled.

1949-55 FORD PASS. CARS & F-1, F-100 TRUCKS

Pass. Car, All Models (1949-55)
F-1 Truck (Late 1950-52)
F-100, 250, 350; P-350, 500 Truck (1953-55)



►**FORD TRUCK NOTE**—This type control used on all F-1, and F-100 Trucks with 3-Speed Std. Trans. or with 3-Speed Heavy Duty Trans.

►*HARD SHIFTING CORRECTION (1953-55 Trucks with H.D. 3 speed Trans.):* To correct this condition install longer levers B5C-7285-B, 7290-B and 7303-A; and stronger rods B5C-7326-A and 7328-A.

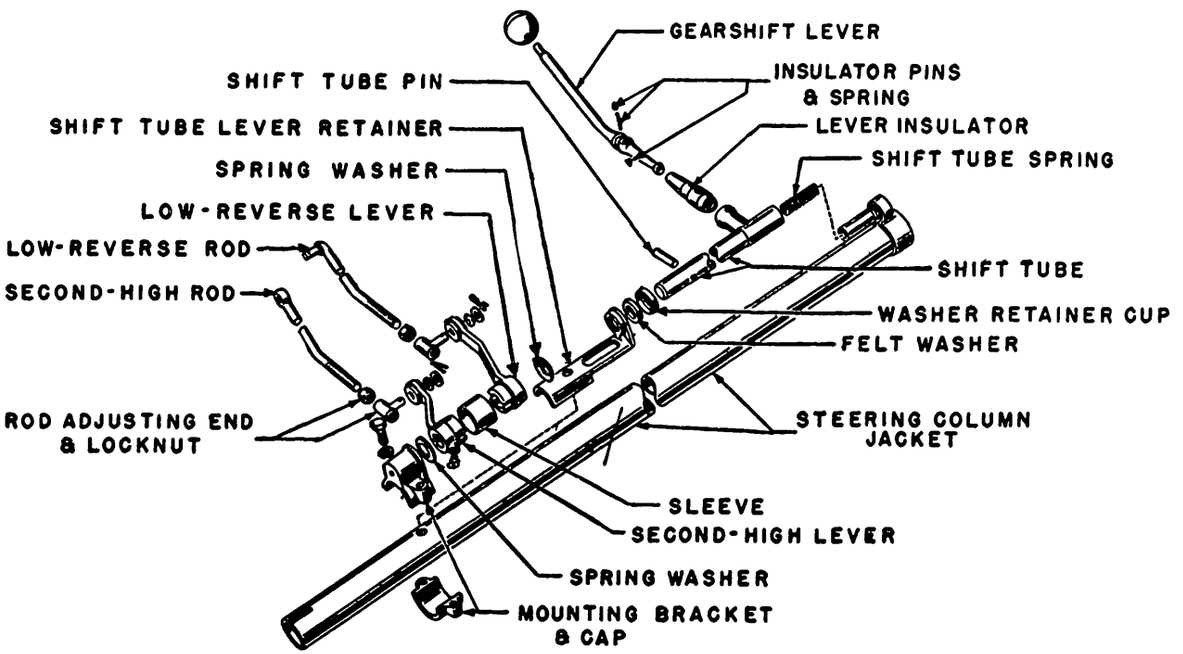
►*GEAR SHIFT BIND CORRECTION (1955 Police Interceptor):* To correct binding condition in transmission gear shift levers, weld 5/16" flat washer Ford No. 44722-S8, on each rod 5/8" from center of hole in end of rod to face of washer.

►*SECOND & HIGH GEAR SLIP-OUT CORRECTION (1955 Pass. Cars & F-100 Trucks):* Slip-out can be caused by—Improper alignment of shift rods; excessive wear at ends of shift rods; or interference between clutch release rod and second and high shifter rod or interference between floor panel and shift rod. To correct this condition proceed as follows:
1) If bent correct contour of second and high shift rod to match new rod or replace rod.
2) If rod wear causes interference with floor pan replace with new rod.
3) Interference between clutch and shift rods can be corrected by removing stock from threaded end of clutch release rod to relieve clearance when clutch is released.

►*GEAR SHIFT LEVER TO TUBE SOCKET ASSEMBLY PRODUCTION CHANGE (1955 Trucks):* When necessary to install new lever on an old tube & socket assembly, drill the tube and socket hole larger (13/64" drill) to provide for installation of the roll pin now used to attach lever to tube.

FORD, LINCOLN, MERCURY 1940-48 TRANSMISSI N CONTR L

DESCRIPTION: Remote control with steering column mounted gearshift lever. Design is similar to type used on previous models except for mounting and other detail changes (see illustration).



ADJUSTMENT (1949-51 Pass. Cars, Late 1950-52 F-1 Trucks): Required whenever steering column position changed or linkage disconnected. Place gearshift lever in neutral position, disconnect both shift levers at lower end of steering column, align shift levers so that gearshift lever freely moves up and down in neutral. Make certain that both transmission case levers are in neutral (can be determined by feel of detent balls engaging neutral notch in shifter shaft cams). Adjust each shift rod by loosening locknut and turning adjusting end on rod until rod can be connected to lever without disturbing position of either lever. Connect rods and check for smooth easy cross-over (up-and-down movement) of gearshift lever in neutral.

Pass. Cars (1952-55); F-100, F-250, F-350, P-350 & P-500 Series Trucks (1953-55)—Place lever in neutral. Remove cotter pins and flat washers from the shift rod ends, then pull rod ends out of gearshift levers. Rotate rod ends either clockwise or counter-clockwise enough to place gearshift levers in same plane when rod ends are assembled to levers. Check gearshift lever for free movement. Position rod ends in levers and install spring washers, flat washers and cotter pins.

Gearshift Lever Position (F-1 Truck)—Check clearance between gearshift lever ball and face of instrument panel in 2nd gear position. This clearance should be 1¾" (in 2nd gear plus overshift movement). If clearance not correct, adjust length of Second-High control rod by turning clevis on end of rod, then recheck shifter lever movement in neutral and make any necessary adjustment to secure smooth cross-over or up-and-down movement of the lever by adjusting the clevis on the Low-Reverse control rod.
►*CAUTION—Do not change length of Second-High Control rod after adjusting gearshift lever position.*

DISASSEMBLY: Disconnect shift rods at levers on steering column. Remove capscrews from bracket securing shift levers and lower end of shift tube assembly on steering column, remove bracket, spring washer, lower (second-high) lever, and spacer from shift tube. Remove shift tube pin, then remove upper (low-reverse) lever, spring washer, shift tube lever retainer, felt washer and washer retainer from shift tube. Move shift tube down until it clears upper bracket on steering column jacket (CAUTION—do not lose spring in upper end of tube), remove shift tube and gearshift lever from car.

REASSEMBLY: Lubricate felt washer with engine oil, assemble all parts by reversing disassembly order. Lubricate levers through fitting in lower (second-high) lever. Adjust control rods after reassembly.
TRANSMISSION CASE SHIFTER MECHANISM: *See "Ford, Lincoln, Mercury" Transmission data.*

TYPICAL 1949-55 PASS. CAR & F-1, F-100 TRUCK TRANS. C NTROL

1949-55 LINCOLN & MERCURY

All Lincoln, Cosmopolitan, & Mercury (1949-51)
Mercury, All Models (1952-55)

▷CHANGES & CORRECTIONS

▷TRANSMISSION GEAR LOCKING COMPLAINT—(First 1949 Cars): To correct first cars without Neutral Spring, this spring should be installed on lower end of steering column to center low-reverse shift lever. Dust shield over low-reverse shift lever hub must first be removed (accessible through cut-out on steering column tube for levers, cut across shield with a chisel and pull shield out of column tube with pliers). Install Neutral Spring as directed under REASSEMBLY data below.

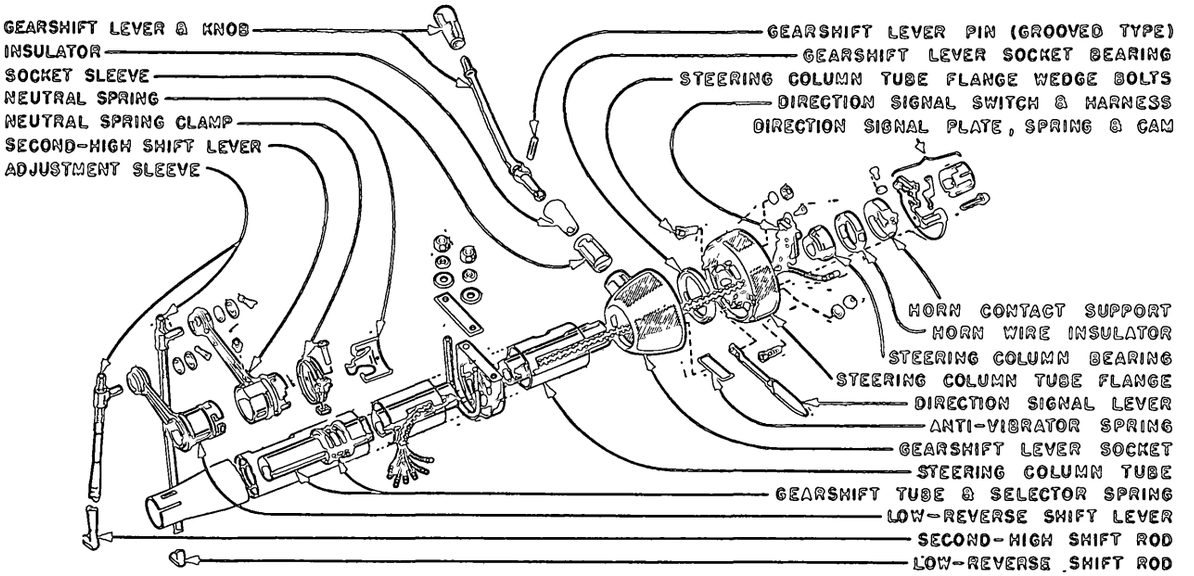
▷HARD SHIFTING COMPLAINTS—May be caused by shift levers out of adjustment (see ADJUSTMENT below), or by interference between low-reverse shift lever and fuel line bracket screw on dash (first cars), or by low-reverse control rod striking flange on dash (first Cosmopolitan cars). Correct by adjusting levers and providing clearance at any point of interference.

▷GEARSHIFT LEVER HINGE PIN CHANGE—If first type pin falls out allowing gearshift lever to come out of shifter sleeve, install latest type grooved pin which is case-hardened (can be identified by fact pins are file-hard).

▷HYDRA-MATIC DRIVE NOTE—Data below applies only to 3-spd. Synchro-mesh transmission cars.

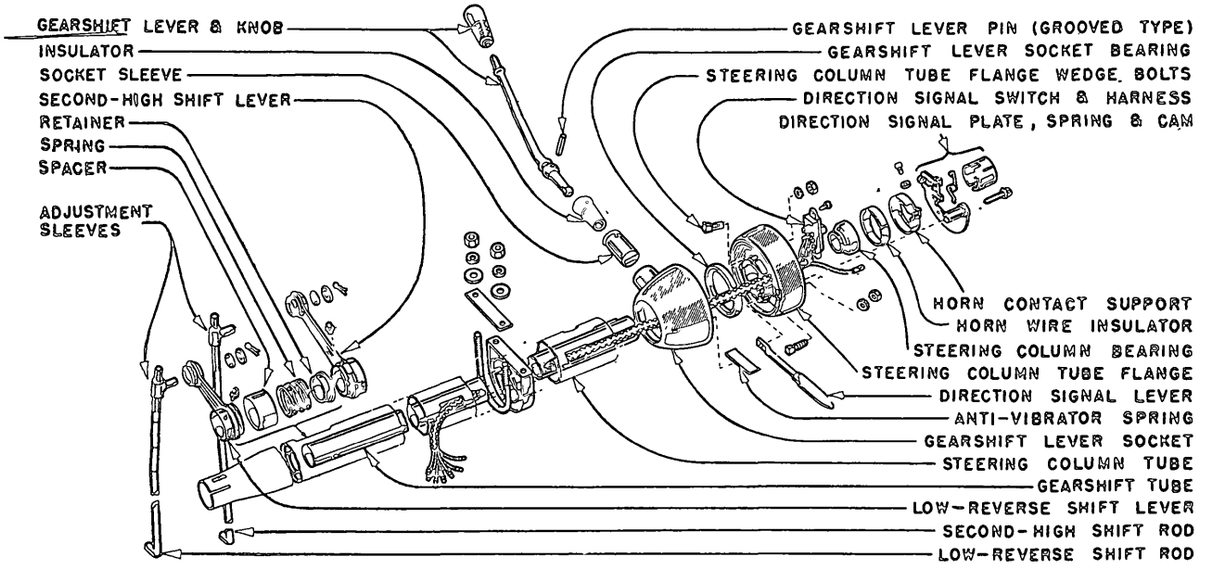
See Lincoln Hydra-Matic Drive Transmission for Hydra-Matic Drive control linkage adjustment.

DESCRIPTION: Remote control with steering column mounted gearshift lever. Design similar to type used on previous models except for assembly of steering column unit (see illustration).



▷1950 Steering Column Lower Gearshift Lever Assembly Change—Transmission selector spring is no longer on gearshift tube assembly. See illustration.

ADJUSTMENT (1949-51): Place gearshift lever in neutral, check for free cross-over (up-and-down) movement of the lever and see that both shift levers on lower end of steering column are in line and centered in opening in steering column. If adjustment required, disconnect both shift rods from shift levers at steering column, see that transmission gears in neutral (can be determined by feel of detent balls engaging notches in shifter cams). See that both shift levers on steering column in alignment and centrally located in column opening, adjust threaded sleeve on end of each rod so that rods can be connected without disturbing position of levers or transmission gears. Connect rods and check gearshift lever action.



1952-55 Mercury—Place gearshift lever in neutral. Remove cotter pins, flat washers, and spring washers from shift rod ends, then pull rod ends out of steering column gearshift levers. Rotate the rod ends either clockwise or counter-clockwise enough to place steering column gearshift levers in same plane when rods assembled to levers, then install spring washers, flat washers, and cotter pins. Gearshift selector levers should be free to move upward or downward in neutral without binding.

DISASSEMBLY: Disconnect both shift rods at shift levers on lower end of steering column. Remove steering wheel (see Steering Gear data), take out woodruff key and spring in steering column, remove horn contact ring and insulator. Remove screw retaining direction signal switch plate and lever, remove handle, lift switch plate out. Loosen, but do not remove nuts on two wedge bolts, push wedge bolts down as far as possible to free flange, lift flange assembly from steering column, pull wiring cable out far enough so that flange can be lifted over steering shaft, lift out bearing sleeve. Drive out grooved pin retaining gearshift lever, remove lever, pull shift tube from steering column. Remove socket assembly sleeve with special tool 7224. Disconnect wires from Direction Signal Switch and horn contact ring, pull wires into steering column, slide socket assembly from tube.

CONTINUED ON NEXT PAGE

1949 LINCOLN & MERCURY TRANSMISSION CONTROL

1950-51 LINCOLN & 1950-55 MERCURY TRANSMISSION CONTROL

1949-55 LINCOLN & MERCURY (Continued)

Shift Lever Removal—Requires removal of steering column tube as follows: Remove pitman arm (puller 3590), roll back floor covering and remove steering column-to-dash cover plates, disconnect direction signal and horn wire connections, free U-bolt and steering column from dash, loosen steering column clamp at steering gear housing, loosen three steering gear-to-frame mounting bolts, slide steering column tube from steering shaft. Remove shift levers from tube.

REASSEMBLY: Install all parts in reverse order of disassembly procedure and note the following precautions and adjustments:

Shift Lever Lubrication—Coat bearing surfaces of both levers with Lubriplate before installation. After assembly completed, lubricate levers through lubricant fitting in upper low-reverse lever.

Steering Column Socket Lubrication—Apply light coat Lubriplate on surface of steering column tube where lower portion of socket assembly contacts tube before installing socket.

►*CAUTION—Lubriplate should not contact pre-lubricated socket bearing.*

Gearshift Lever Socket Sleeve—Install sleeve to retain socket. Sleeve is light press fit and should be tapped into place with blunt driver.

►*CAUTION—Holes in sleeve must line up with holes in socket (for installation of gearshift lever pin).*

Steering Column Shift Tube & Gearshift Lever—When installing tube, turn tube so that lugs enter slots in shift levers. Install gearshift lever and see that lever engages shift tube. Use only latest type grooved pin to retain gearshift lever.

►*CAUTION—Use only case-hardened grooved type pin at this point (replaces original solid pin).*

Neutral Spring Installation (1949 Cars—see Correction note above)—With both the shift levers aligned one above the other, and centrally located in steering column opening, place neutral spring on column tube when center prong in slot of low-reverse lever and side prongs contacting upper edge of column tube opening. Clamp spring in this position with a hose clamp (B-8287-A) or use regular backing light switch clamp.

►*CAUTION—Center prong on spring must be free.*

Steering Column Tube Flange—Press two wedge bolts down which will spread wedges and permit flange to slide on steering column. Tighten wedge bolts lightly.

►*CAUTION—Overtightening wedge bolts will cause the wedges to damage assembly.*

Horn Insulator & Contact Ring—Insulator must be positioned in tube cutout and tab on contact ring must enter cutout in insulator. Tighten retaining screw only enough to hold ring in position (overtightening screw will distort ring).

Steering Wheel Clearance—After wheel installed, check clearance between wheel and steering column tube flange. If not exactly 1/16", loosen clamp at instrument panel, move column for correct clearance (do not tighten clamp at lower end of steering column tube until this adjustment made).

Shift Lever Adjustment—See ADJUSTMENT above.

TRANSMISSION CASE SHIFTER MECHANISM: *See "Ford, Lincoln, Mercury" Transmission data.*

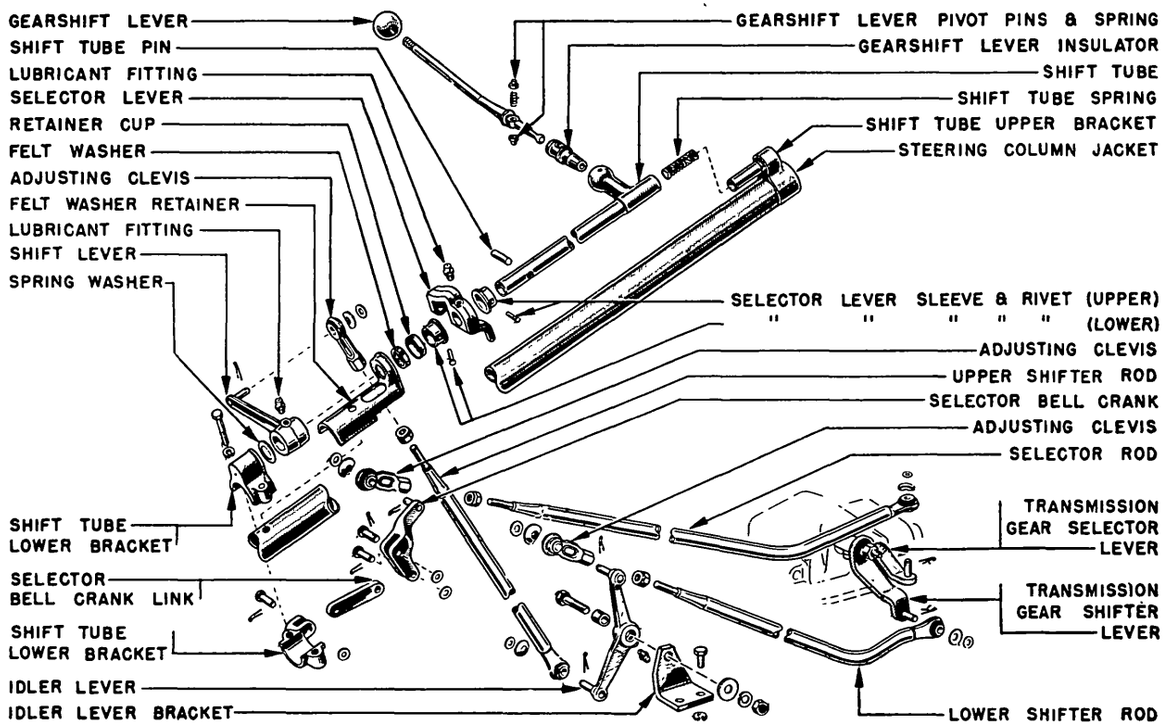
FORD PARCEL DELIVERY TRUCKS

Ford Parcel Delivery, All Models (1950-52)

►**TRANSMISSION CONTROL NOTE**—Control used on these trucks is not same as used on F-1, F-100 Trucks.

DESCRIPTION: Remote control type with gearshift lever on steering column pivoted in socket on upper end of single shift tube mounted in brackets on steering column. Shift tube has loose gear selector lever (positioned by upper and lower sleeves riveted on tube) so that up-and-down movement of the gearshift lever actuates the gear selector lever on the transmission case cover (through selector bell-crank and selector rod).

ADJUSTMENT: *Two separate adjustments required:*



1) Shift Rod Adjustment—Place gearshift lever on steering column in neutral position. Disconnect lower (adjustable) shift rod at idler lever on left frame side rail. Make certain that transmission gear shifter lever is in neutral position (can be determined by feel of detent poppet balls engaging notches in shifter rail). Adjust clevis on idler lever end of lower shift rod until pin on idler lever enters hole in clevis freely without disturbing position of transmission gear shifter lever or idler lever. Tighten clevis locknut and connect rod.

2) Selector Rod Adjustment—Move gearshift lever on steering column up-and-down in neutral (cross-shaft travel) and measure travel of gear selector lever and shifter shaft in transmission case cover. This travel must be .23" minimum from full "in" to full "out" position. To adjust, disconnect selector rod at selector bell crank on steering column, adjust clevis on rod until correct travel secured.

DISASSEMBLY: Disconnect selector rod and upper shifter rod at levers on steering column, disconnect and remove selector bell crank link. Remove cap-screws from shift tube lower bracket, remove bracket (lift off lower half, raise upper half up slightly to disengage dowel from hole in steering column jacket and then slide bracket off end of shift tube). Remove spring washer from end of shift tube, remove shift tube pin from shift lever, then remove following parts from shift tube: shift lever, felt washer retainer, felt washer, and retainer cup. Remove selector lever sleeve rivets, slide sleeves and selector lever off lower end of shift tube. Move shift tube down until it clears upper bracket (CAUTION—do not lose spring in upper end of tube), remove shift tube and gearshift lever assembly.

REASSEMBLY: Lubricate felt washer with engine oil, assemble all parts by reversing disassembly order. Lubricate shift lever and selector lever through lubricant fittings on levers. Adjust control (see Adjustment above).

TRANSMISSION CASE SHIFTER MECHANISM: *See "Ford Truck 3-Speed Heavy Duty" Transmission Data.*

1950-52 TYPICAL FORD PARCEL DELIVERY TRUCK TRANS. CONTROL

1948-51 HUDSON DRIVE-MASTER

6 & 8, All Models (1948-49-50)
Pacemaker 4A & Super Six 5A (1951)

▷DRIVE-MASTER FUSE CHANGE: 15 ampere fuse should be used on all cars (replacing 10 ampere type used on first cars). This fuse located on back of control switch (1948-49), in switch lead (beginning 1950).

▷OVERDRIVE TRANSMISSION NOTE: Overdrive is separate option and may be found installed on cars with Drive-Master Transmission. Overdrive unit is Warner Type R10D. *See Warner Type R10 Overdrive*

DESCRIPTION: Drive-Master transmission consists of a conventional 3-speed transmission with automatic controls as follows:

Vacumotive Drive: Automatic clutch control similar to type used on cars without Drive-Master except for Throttle Lock for which adjustments are given below. *See Hudson Vacumotive Drive data.*

Drive-Master Control Units: Similar to design used on previous Hudson models except for different mounting of units and linkage changes as follows:

Transmission Power Unit—Complete unit (Power Cylinder, Transfer Diaphragm Cylinder, and Solenoid Valves) mounted on bracket bolted on left side of engine block.

Transmission Switch—Mounted on power unit mounting bracket on left side of engine.

Transfer Mechanism—Mounted on bracket on rear of power unit mounting. Unit is new design three-lever type with power lever (inner) linked to power cylinder by non-adjustable strap, manual lever (outer) linked to gearshift lever on steering column, and center gear engagement lever linked to shift lever on transmission case by new adjustable rod. This center lever has transfer key (operated by Transfer Diaphragm Cylinder) by which lever is locked to inner lever (for automatic shifting), or outer lever (for manual shifting). Detent ball and spring is provided for both inner and outer levers to positively locate them in each gear position.

Instrument Panel Control Switch (1948-49): Rotary type on instrument panel (center "off" with right and left "on" positions).

Center "Off" Position—Manual gear shifting and clutch operation.

Left "On" Position—Manual gear shifting with automatic clutch operation (Vacumotive Drive on).

Right "On" Position—Automatic gear shifting and clutch operation (Drive-Master & Vacumotive Drive on).

Instrument Panel Control Switch (1950 & Later): Two button type on instrument panel with separate "on" and "off" buttons.

Left "OFF" Button—Pressing button in provides manual gearshifting and clutch operation.

Right "HDM" Button—Pressing button in provides automatic gearshifting and clutch operation.

Drive-Master Fuse: Located on back of switch (1948-49), in cartridge type holder in control switch lead (beginning 1950).

Fuse Capacity—15 amperes.

▷*CAUTION—15 ampere fuse replaces 10 ampere fuse used originally on 1948-49 cars.*

OPERATION: All units operate in exactly same manner as on previous models. Shifting limits are as follows:

Automatic Second-to-High Shift—9.5 to 14 MPH.

Automatic High-to-Second Shift—9 to 12 MPH.

Vacumotive Drive Cutout (In High Gear)—16 MPH. (minimum), 21 MPH. (maximum) and must be inoperative at all higher speeds.

CHECKING & ADJUSTMENT: Check all of the following points before making any Drive-Master adjustments:

1. Engine Performance—Must be properly tuned up with idle speed set at 580-600 RPM. with Drive-Master "on" button pressed in. Engine vacuum reading must be at least 17-18" to insure proper engine performance and Drive-Master operation.

2. Vacuum Connections—Check lines for leaks.

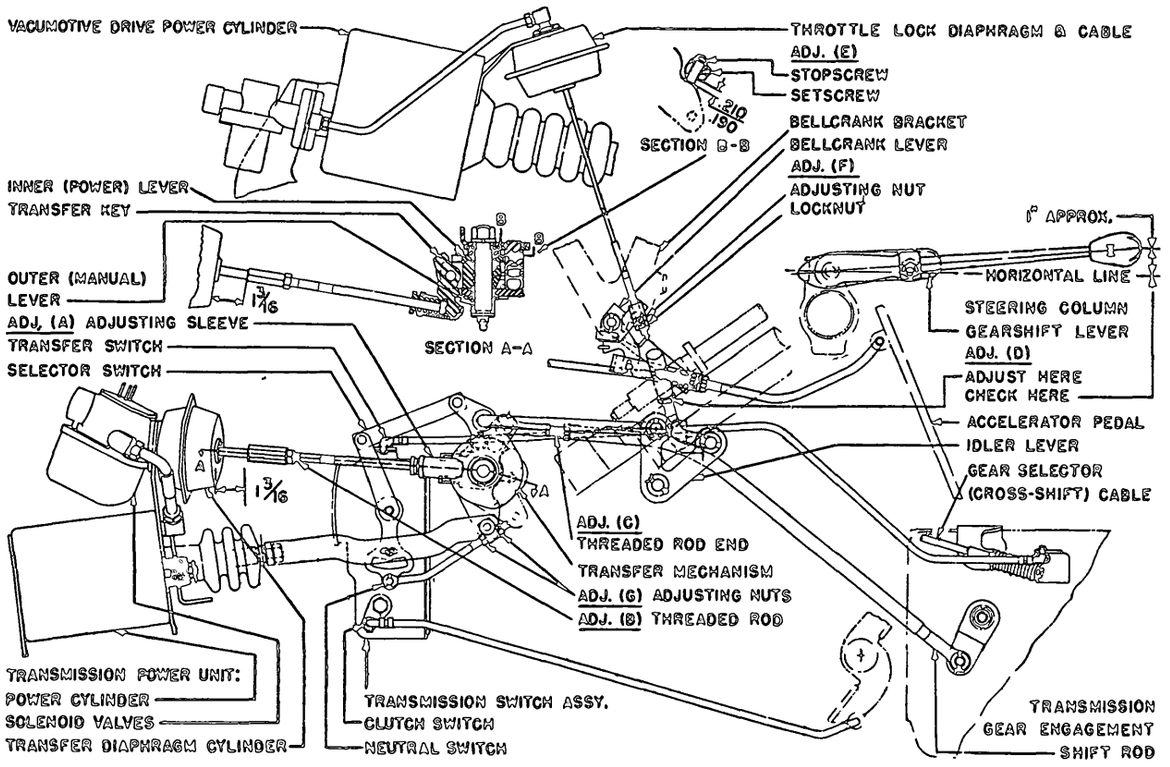
3. Battery—In good condition and not discharged (gravity reading of not less than 1225).

4. All Electrical Connections Clean & Tight—Check following plug connectors particularly: Clutch Power Unit Solenoids, Accelerator Switch, Transmission Power Unit, Transmission Switch, Governor, and Shift Rail Terminal.

5. Accelerator Linkage—Must work freely and return solidly against stop on accelerator switch when accelerator pedal is released. This is important to insure clutch release for Drive-Master operation. Adjust accelerator pedal rod so that carburetor throttle valve is wide open just before accelerator pedal touches stop (cars without overdrive), stem of kick-down switch (cars with overdrive), or tip of pedal strikes floor mat (Pacemaker without overdrive).

6. Clutch Pedal Free Travel—Must be 1½". Starter switch should become operative (starter will crank with starting button depressed) before pedal is within 2" of floor.

7. Vacumotive Drive & Drive-Master Linkage—Must work freely without binding at joints. Check with control switch "off" by opening throttle slightly and releasing pedal slowly. Accelerator bellcrank arm must return solidly against stop on bracket.



8. Vacumotive Drive Adjustments—Check operation and make all necessary adjustments.

See Hudson Vacumotive Drive in Clutch Section.

9. Drive-Master Adjustment—After all above points checked, adjust Drive-Master units as follows:

(A) Transfer Key Ball Joint: Joint at transfer key end of diaphragm cylinder rod must operate freely without any perceptible endplay. To adjust, loosen lock-

CONTINUED ON NEXT PAGE

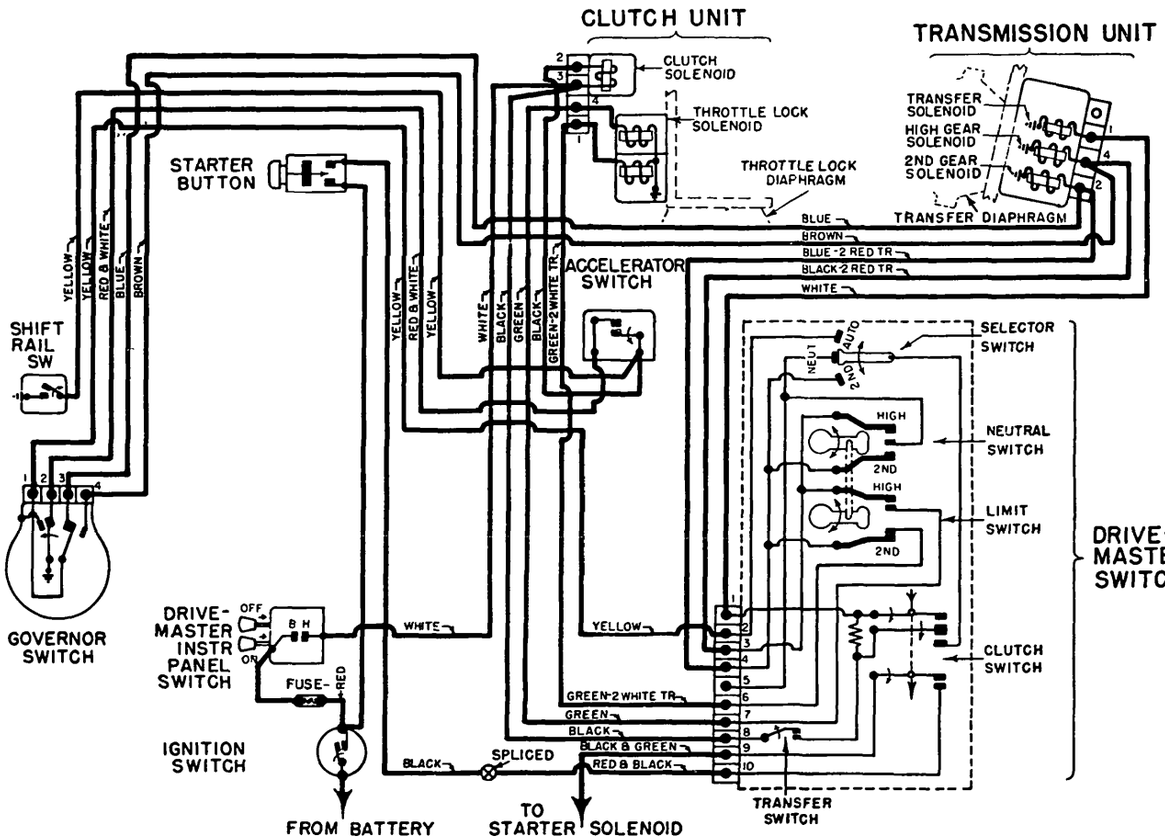
1948-49 DRIVE-MASTER ASSEMBLY

1948-51 HUDSON DRIVE-MASTER (C nt.)

nut on rod, turn adjusting sleeve inward to take up all play. Ball joint must work freely.

Lubrication Note—Lubricate with viscous chassis lubricant through grease fitting on transfer key (pull diaphragm rod forward for clearance).

(B) Transfer Diaphragm Rod (1948-49): With steering column shift lever and outer lever of transfer mechanism in neutral, check distance from rear face of diaphragm cylinder to front face of rod end (round portion of rod), which should be 1 3/16". To adjust, hold diaphragm rod from turning with wrench on hexagonal end, loosen locknut, turn outer rod in or out (knurled section provided for gripping with pliers).



(1950 & Later)—With engine not running, place steering column shift lever in High Gear, adjust length of selector diaphragm rod by loosening locknut and turning rod (knurled section provided for gripping rod with pliers) until selector key bottoms solidly in slot in hand shift lever. Check this adjustment by starting engine and shifting transmission to Neutral—selector key should bottom solidly in slot in power shift lever.

►***CAUTION—Do not allow diaphragm rod to turn when adjusting (will damage diaphragm).***

(C) Transmission Shift Rod (All Car Models except Pacemaker): See that the transmission gears are in neutral, disconnect shift rod front end (center lever connection at transfer mechanism). Push or pull slightly on rod until neutral cross-over action is free, see that gear engagement lever is in neutral position (jiggle lever to engage neutral detent), adjust rod length by loosening locknut and turning end fitting so rod can be connected without disturbing position of transmission shift lever or transfer gear engagement lever. Connect rod and recheck cross-over action. Re-adjust by shortening or lengthening rod ½-turn at a time until action is free.

Pacemaker Models—Check in same manner as the others (above), adjust by backing off one nut tightening opposite nut at end fitting on forward end of rod.

(D) Manual Lever (Gearshift Lever Position): Adjust rod linking shifter shaft on steering column to idler lever at lower end of column (loosen locknut and turn rod in end fitting) until gearshift lever under steering wheel is approximately 1" above a horizontal position in neutral.

DRIVE-MASTER WIRING DIA RAM

(E) P wer Lever Stop: Run the engine for vacuum, place control switch in HDM position (right hand "on" position), shift to second gear. Turn stopscrew on transfer mechanism down until it just contacts power lever (inner lever), then turn stopscrew down additional ½-turn, tighten Allen head setscrew to lock stopscrew in this position.

(F) Throttle Lock: Run engine and connect jumper wire from battery negative post or other hot terminal to either of the two upper throttle lock solenoid terminal pins (lower pin not used) to cause throttle lock to operate. Loosen locknut and turn adjusting nut on threaded fitting at lower end of throttle lock cable until accelerator pedal bellcrank lever is held solidly against stop on bellcrank bracket when accelerator pedal is depressed, tighten locknut.

►***CAUTION—Cable must not be adjusted so short that accelerator cross-shaft is deflected when throttle lock operates.***

(G) Neutral Switch: Run engine with control switch HDM position, shift transmission to neutral. Disconnect transmission shift rod at forward end (center lever of transfer mechanism), move gear shift lever on steering column to Second Gear position, then back to Neutral position. Jiggle shift rod until cross-over action in transmission is free. Check length of shift lever rod in relation to position of transfer mechanism lever from which it was disconnected but do not chang adjustment f this rod. Adjust neutral switch rod length (see below), then repeat test procedure (move gearshift lever to Second, back to Neutral, check rod length), until gear shift rod can be connected without disturbing position of levers.

►***CAUTION—Do not change transmission shift rod length when making this adjustment.***

Neutral Switch Rod Adjustment—Adjust by backing off one nut, and tightening opposite nut, on threaded end of neutral switch rod at transfer mechanism center lever. If transmission shift rod appeared to be too short when making above test, shorten neutral switch rod by turning up rear nut, if shift rod appeared to be too long, lengthen neutral switch rod by turning up front nut. Tighten opposite nut to lock adjustment in each case.

Final Performance Check: After all adjustments completed, check for free cross-over action (gear shift lever must return to second-high side from any position in neutral) and transfer key should move from engagement with power lever to engagement with manual lever as steering column gear shift lever is moved upward in neutral.

►***NOTE***—If cross-over action not free, recheck Transmission Shift Rod Adjustment (C) and Power Lever Stop Adjustment (E) above. See that cross-over switch rod is centered in clip at clutch housing.

DRIVE-MASTER SERVICING: All units which do not operate satisfactorily after adjustment should be replaced.

TRANSMISSION SERVICING: ***See Hudson Transmission.***

REMOVAL & INSTALLATION OF DRIVE-MASTER: Units can be removed separately as follows:

Power Cylinder & Transfer Diaphragm: Disconnect diaphragm engaging rod from rod end, disconnect shift strap by removing bolt attaching strap to power cylinder. Disconnect battery cables, remove battery and battery tray and support. Disconnect vacuum lines at transfer diaphragm solenoids. Re-

C NTINUED N NEXT PA E

1948-51 HUDSON DRIVE-MASTER (Cont.)

move cotter pins, nuts, ferrules, washers, and rubber bushings from power cylinder mounting studs, remove power cylinder and diaphragm assembly.

▷*INSTALLATION CAUTION*—Adjust Transfer Key Ball Joint (Adjustment A), and Transfer Diaphragm Rod (Adjustment B) after unit re-installed.

Power Unit Mounting Bracket: To remove this bracket from the engine, first remove power unit and transmission control switch (see above), disconnect shift rod and cross-over rod at power shift and at manual shift bell-crank, disconnect clutch rod at transmission control switch. Remove two bolts at lower bracket support, one bolt at oil pan at forward end, two nuts and lockwashers at side of cylinder block. Lift off bracket with power shift shaft and shift levers as an assembly.

Transmission Control Switch: Remove distributor (6 Cyl. models only). Disconnect clutch operating rod, transfer switch rod, neutral and limit switch rod, and selector switch rod. Disconnect wiring harness plug. Remove bolt, lockwasher, and nut at top and bottom of switch, remove switch from mounting bracket.

Drive-Master Shift Shaft & Shift Shaft Levers: Remove shift shaft nut at rear of support bracket (disconnect transfer switch rod at switch for wrench clearance). Disconnect power shift rod by taking out cotter pin and clevis pin. Slide shift shaft out toward fender (CAUTION—use care not to lose detent balls and springs which may fall out of retainers).

▷*INSTALLATION CAUTION*—When re-installing shift shaft, lubricate detent balls with water-resistant grease and make certain detent ball springs correctly positioned as follows:

Hand Shift Lever Detent Ball Spring—Part No. 163442 (19 pound tension when compressed to 11/16"). Install this spring in Drive-Master mounting bracket pin for hand shift lever assembly.

Power Shift Lever Detent Ball Spring—Part No. 41236 (30 pound tension when compressed to 13/16"). Install this spring in shift shaft mounting bracket recess.

▷*TRANSFER KEY HUB BUSHING REPLACEMENT*—If replacement of this bushing necessary, remove old bushing with driver having .625" pilot. Install new bushing (bushing inside diameter after assembly must be .625-.626").

NOTE—Shift shaft bushings also have inside diameter of .625-.626" to allow shaft clearance of .0023-.0035".

1941-47 HUDSON HANDI-SHIFT

Six, All Models (1941 to 1947)
Eight, All Models (1941 to 1947)

DESCRIPTION: Remote control type with steering column mounted gearshift lever.

Steering Column Unit—Cross-shift control cable ends protected by boots at both steering column and transmission case ends. Operating rod (gear engagement rod) has new type ends with adjusting clevis at forward (steering column) end of rod.

Transmission Case Shifter Mechanism — New type design used in conjunction with new synchromesh transmission. Gears are engaged by lever on inner end of shaft in side of transmission case which engages upper or lower shifter rail in case. This shaft and lever are shifted in or out (for cross-shift at neutral) by an inner lever on a vertical cross-shift shaft. Selector cable is connected to outer lever on this vertical shaft.

ADJUSTMENT: Operating Rod (Gear Engagement)—With gearshift lever and transmission gears in neutral position, disconnect operating rod at lever on steering column by removing cotter pin and clevis pin, loosen locknut and turn clevis on rod until clevis pin can just be installed without disturbing position of transmission case shift lever and with gearshift lever in neutral and at right angles to centerline of car. Tighten locknut and connect rod.

Selector Cable (Cross-shift)—Place steering column shift lever in Low-Reverse or 'up' position at neutral and block in this position while adjustment being made. Loosen selector cable conduit bracket capscrew at lower end of steering column and move conduit bracket up until all slack removed from cable and shift lever at transmission case is fully over in Low-reverse position (lever to rear), tighten bracket capscrew securely. See that anchor on steering column end of cable (at lower end of control lever pushrod) has clearance at top and bottom of travel.

SERVICING: Removal of steering column unit requires that horn button and steering wheel be removed first. Steering column can then be serviced as follows:
